PRESERVATION OF THE COUNTRYSIDE IN BRITAIN

THE two outstanding features of the year covered by the ninth annual report of the National Parks Commission* have been, in the Commission's own judgment, a series of Acts of Parliament with a direct bearing on its work, and Ministerial decisions on three extensive development proposals in national parks in Britain. Referring specifically to major industrial developments in the Pembrokeshire Coast National Park and the decision to sanction the construction of a nuclear generating station at Trawsfynydd in Snowdonia, the Commission affirms that, if it is to discharge the responsibilities which Parliament has entrusted to it, it must increasingly strive to ensure that every possible alternative site has been fully considered before permission is granted for such developments in a national park. It is reluctant to believe that, although it has been decreed in the over-riding national interest that particular major industrial undertakings shall be permitted in national parks, this signifies that national parks are being devalued as a national asset by those with whom the ultimate responsibility for these decisions rests.

Scant reassurance, however, on this point is to be found in the debate in the House of Commons on January 30 on the National Parks (Amendment) Bill introduced by Mr. A. Blenkinsop, though reference was freely made to the Commission's report in that debate; and it is in the light of that debate that the bearing on the Commission's work of the Acts in question—the Land Powers (Defence) Act, the Litter Act, the Local Government Act, the Milford Haven Conservancy Act and the Opencast Coal Act—is best appreciated. In so far as some of these likewise bear on the work of the Nature Conservancy†, a similar remark might apply to the ninth report of the Conservancy. Except against that background, the record of quiet but steady progress recorded in these two reports could engender an optimism that is quite unjustified and out of keeping with what remains to be done and the real national needs in regard to amenity and conservation.

Mr. Blenkinsop's Bill was opposed by the Minister of Housing and Local Government, Mr. H. Brooke, who pointed out quite rightly that the Bill was, in effect, a Financial Bill and that Parliament does not accept Private Members' Bills which propose the expenditure of public money. It is the tradition of the House that it should be the Government which shall choose and decide which proposals for additional expenditure should be placed before Parliament. Because of this principle, which is independent of the merits of the detailed provisions of the Bill from the point of view of the national parks, Mr. Brooke did not examine the Bill further. Most of its recommendations are, in fact, based on recommendations made to the Ministry by the Commission or by the County Councils Association; but in directing attention to this principle, Mr. Brooke placed the responsibility for the financial difficulties of the national parks in Britain fairly and squarely where it rests—with the Government.

There has never been any adequate financial provision made for the work of the National Parks Commission, either for its positive and constructive activities or even for its ordinary administration, largely because the burden of serving a national interest has been placed on the constituent counties, some of which are financially very weak. It is not, therefore, sufficient for Mr. Brooke to decline to undertake that the Government would introduce a Bill on the subject. If the idea of national parks is to have any real meaning, the Government must give serious consideration to their financial position and take early and adequate steps to meet their needs: a need which indeed is accentuated by the other grave threat to the whole conception—that of development. To concert the measures which keep the damage from development to a minimum usually demands much negotiation, consultation, and examination of sites, all of which costs money, and taxes to the limit the resources of the Commission and the other amenity societies.

Mr. Blenkinsop indicated clearly enough the minimum requirements. Less than £100,000 a year is being spent on the national parks of Britain, in the areas themselves or in the offices of the Commission. In the first place he proposed, in accordance with the Commission's own request, that the Minister's powers of providing grants should be widened to include any work done by the national park authorities under the broad enabling powers of the principal Act. This, in practice, would, for example, permit grants for such purposes as providing information centres in the parks, publicity action, anti-litter campaigns, etc. Secondly, he suggested the removal of those restrictions upon the powers of the Commission which prevent it from carrying out work which is the statutory responsibility of some authority but which (again often for financial reasons) is not being discharged. Thirdly, he strongly urged that, as recommended both by the Commission itself and the County Councils Association, the Minister should be allowed to make grants for the administrative expenses of the parks.

There were other minor suggestions in relation to the long-distance footpaths, the provision of wardens and making planning authorities responsible for the creation of new rights of way and their maintenance in national parks; but although the debate was poorly attended the Bill had support from all sides of the House of Commons, and it focuses attention on the neglect of the Government, when the Act was originally passed and since, to provide the financial resources without which the purpose of the Act cannot be achieved. The Commission itself made further representations to the Minister during the year regarding the need for early amendment of the Act, but in his reply of April 11, 1958, Mr. Brooke held out no hope of Parliamentary time being available for a Bill on this subject. The Nature Conservancy is more restrained in its comments on financial needs, but the report makes it clear enough how far its scientific work and the management of the reserves are limited by lack of funds. The recommendation of the Select Committee on Estimates that "Ways and means should be sought for strengthening the Conservancy's liaison with the universities and for increasing the contribution to scientific research to be expected from them" is warmly welcomed.

---

* National Parks and Access to the Countryside Act. Ninth Report of the National Parks Commission for the year ending September 30, 1958. Pp. iv+79+8 plates. (London: H.M. Stationery Office, 1958.) 5*s*. 6*d*. net.

† Report of the Nature Conservancy for the year ended 30th September, 1958. Pp. vi+119+14 plates. (London: H.M. Stationery Office, 1958.) 6*s*. 6*d*. net.

The National Parks Commission in the present report also refers to the Land Powers (Defence) Act, 1958, concerning which the Commission was consulted, and in which provision was made that military manœuvres commissions should include, in addition to a member nominated by the Commission, "at least one person appearing to the Minister to be specially qualified to watch over the amenities of the areas in which the manœuvres are to be held". The Commission also welcomes the provision in the Act which empowers Service Ministers to use land occasionally for training and minor exercises, and thus enables them to reduce their holdings. The Litter Act, which received Royal Assent last July, is also regarded as a big step forward in the campaign against litter ; but it could well increase the financial needs of the Commission if the Act is to be made effective. The Local Government Act, 1958, leaves undisturbed the existing grants to local authorities under the National Parks and Access to the Countryside Act, 1949, but it is welcomed as a recognition of the national interest in national parks and in areas of outstanding natural beauty and as leaving the way open for extending these grants. While regretting, however, that further provision for opencast coal operations is made in the Opencast Coal Act, 1958, the Commission welcomes the improved safeguards for amenity contained in the Act.

These provisions follow corresponding sections in the Electricity Act, 1957, and the Milford Haven Conservancy Act, 1958, and these sections are heartening examples of the greater concern for the preservation of amenity which is now felt both in Parliament and in Britain generally. While it is true that the work consequent on the passing of the Town and Country Planning Act of 1947 and the National Parks and Access to the Countryside Act of 1949 has had a beneficial effect on the landscape, and that the cumulative effects of planning control have been considerable, the very passage of these new Acts and the granting of Ministerial consent for development proposals in national parks which have caused such disquiet to the Commission show the extent to which the effectiveness of its work lies largely outside its control. It depends on the amount of support which the Government is prepared to give for both amenity and conservation, at least in limited and specified areas, as an over-riding national interest, and to provide the financial and other resources to maintain that interest in the face of either departmental or sectional or local interest. That in turn ultimately depends on the development of an informed public opinion, alert to support the study work of planning authorities, within and outside national parks, and determined to safeguard with intelligent care the traditional and most vulnerable and often irreplaceable beauty of the countryside of Britain.

NEW ASPECTS OF THE GENETIC CONTROL OF INDUSTRIAL MELANISM IN THE LEPIDOPTERA

By DR. H. B. D. KETTLEWELL
Nuffield Fellow in Genetical Research, University of Oxford

AN absolute necessity to achieve dark coloration in order to preserve crypsis and survive has, in the past hundred years, confronted a large number of species of moths. County lists bear witness to the fact that some have failed and have been driven out of urban areas and their surroundings : the requisite mutations have not taken place in time. In at least two species (*Procus literosa* Haw. and the *Apamea characterea* Hb.), we have evidence that, after local extinction, an urban area has later been repopulated by melanic forms of the same species[1]. Until recently, we had assumed that successful industrial melanics had nearly always come about by the successful mutation of single dominant melanic genes, which, in one step, changed the insect from white to black[2].

In *Biston betularia* L., the peppered moth, I have shown by mark–release–recapture experiments that the cryptic advantage derived from this colour-change could alone account for the spread of industrial melanism[3]. Nevertheless, it has also been shown that, apart from colour, there are profound behavioural and physiological differences[4,5]. I have postulated theories based on the fact that melanic mutants, dominant in the few known instances and similar in every way to those spreading to-day throughout the industrial areas of the world, are to be found in moth populations, frequently as a balanced polymorphism, in many parts of the world remote from the effects of industrialization : the Caledonian forests of Scotland ; the sub-Arctic of Canada ; and the rain forests of South Island, New Zealand[6]. I have suggested that this same basic one-gene switch-mechanism has probably been used in the past for very different reasons when blackness conferred advantage[7] ; for the assimilation of heat in cold climates; in dark rain forests; or possibly before deciduous trees succeeded the conifers in the northern hemisphere. In this instance, then, the 'pre-adapted' gene of Cuénot[8] is seen, not as a fortuitous happening, as has recently been suggested[9], but as a mechanism fulfilling recurring, though differing, needs which have from time to time been demanded for periods in the past history of a species. During these periods dominance has been achieved by natural selection.

Apart from this mechanism, we are finding evidence that others exist to promote darkness. One of these involves the use of polygenes, which bring about the gradual darkening of a normal population. There are certain species of Lepidoptera that have failed to mutate to a successful dominant melanic but have continued to survive in their typical form in urban areas. It has been repeatedly noted that, when these 'typicals' were compared with rural forms of the same species, the urban populations were much the darker. For example, *Gonodontis bidentata* Cl., which does not fly actively, has a single dominant black mutant, form *nigra* Prout. On Cannock Chase outside Birmingham, this comprises more than 50 per cent of the population. In central Birmingham, however, that mutant does not occur, but the typical specimens, which still survive there, are darker than their normal forms elsewhere. A large number of species in Sheffield, London and elsewhere fall into this category.

It is interesting to reflect on whether these darkening genes are the same as those which are responsible for blackening the heterozygotes of unifactorial melanics. We have previously recorded that the earliest heterozygotes of *B. betularia*, extracted from collections made in the past century, are different from the majority of specimens collected recently[10]. They were in fact somewhat intermediate in character, with varying degrees of white markings on the wings—a condition rarely found to-day. *B. betularia* form *carbonaria* now has complete dominance, the heterozygotes being indistinguishable from the homozygotes in the majority of individuals. Dominance has been achieved by the selection of modifiers in the gene-complex. Present indications are that in *B. betularia* many of these modifiers are not the same: the few remaining recessive typicals occurring in Birmingham are more variable, but not on an average darker, than rural ones. Probably the insect is so white, anyway, that it has not had the opportunity of mobilizing its polygenes for darkening, because the white form is always conspicuous in urban areas. Selective predation between typical individuals has, therefore, not taken place: they are eliminated indiscriminately. They continue to appear because of the advantage of the heterozygous *carbonaria* in the population.

Apart from the polygenic form, we encounter other modifications of the inheritance of melanism. In north Germany, *Lymantria monacha* L. has a gradation of phenotypes from white to black. The blackest (f. *atra* Linslow) is the result of three dominant genes (one sex-linked). Melanics of multifactorial origin are, surprisingly, uncommon in the Lepidoptera.

Sex-limited melanics, found in the female only, are known in a few species (*Phigalia pedaria* Fab.)[11], though whether the gene is in the Y-chromosome, or inherited cytoplasmically, has not at present been ascertained.

Until recently, I had repeatedly stated that no example was known of a *recessive* melanic mutation having spread: that recessive melanics were always rare, sub-viable and for the most part limited to non-cryptic species in which black forms, in past periods, had never been of use to the species[12]. This remains substantially true, but we have now found one: the bombycid moth, *Lasiocampa quercus* L., the oak eggar, and its two dark forms, which are increasing rapidly. One is green-black, *olivacea* Tutt (*olivaceofasciata* Cockerell), to which, until recently, all melanic *quercus* were referred. The other, *lurida* Cockayne[13], recognizably different when freshly hatched, is red-black. It seems likely that the two forms are modified expressions of the same recessive gene, or possibly they are alleles.

The oak eggar, in its northern form *callunae*, at times swarms on the heavily polluted Yorkshire moors. Unfortunately, it has a two-year life-history, the larva occurring in even years only and the moth in odd. In a sample of 493 moths collected in 1957, 23 (4·7 per cent) were of the dark recessive forms, so that about a third of the population were heterozygotes assuming equal viability of the genotypes. At present we cannot identify these with certainty, but there is evidence that a majority of the typical population are darker to-day than they were twenty years ago. Similarly, present-day melanics are darker than the earliest specimens taken from the same moor when they formed about 1 per cent of the population (though they do not fade).

A further interesting point in regard to form *callunae* is that, in Yorkshire, about 4 per cent of the wild larval population are black (82 in a random sample of 2,000 in 1956) though normally they are yellow-brown in colour (Fig. 1). They are hairy but are predated by cuckoos. A proportion (about 50 per cent) of the black larvæ produce black moths, as do a very much smaller proportion (less than 2 per cent, 1956) of yellow-brown larvæ. Natural selection, working on partial linkage between the genes controlling black larval and imaginal colouring, is the most probable explanation of the situation[14]. We are at present testing the cross-over values both in this locality and in other places where the same phenomenon occurs.

The female of the oak eggar, an insect of great size, is typically pale yellow. It hatches in the daylight hours and sits on heather stems, rarely flying except at night. The males, which are chocolate brown with bright yellow conspicuous bands, particularly on the underside, assemble in great numbers to them. The males, therefore, fly actively, in fact wildly, by day. To the human eye, form *olivacea* females were invisible on their backgrounds at, on an average, more than seventeen yards. The yellow female, on the other hand, was still visible at fifty-seven yards.

During the summer of 1957 we undertook an intensive study of this moth on Rombolds Moor, in June, where it was abundant. This is part of Ilkley Moor and is within fourteen miles of Bradford, Leeds and Skipton. The heather, walls and even the ground itself were black with pollution. Each day we observed large flocks of black-headed gulls (*Larus ridibundus* L.) flying slowly over the heather and dropping into it every few yards as they gorged themselves on the female eggars. The black-headed gull has only comparatively recently, in the past thirty years, extended its summer range to central England. Because of the insufficiency of melanic females, we were unable to undertake extensive mark-releases, comparable with those we had previously carried out on the peppered moth. On one occasion,

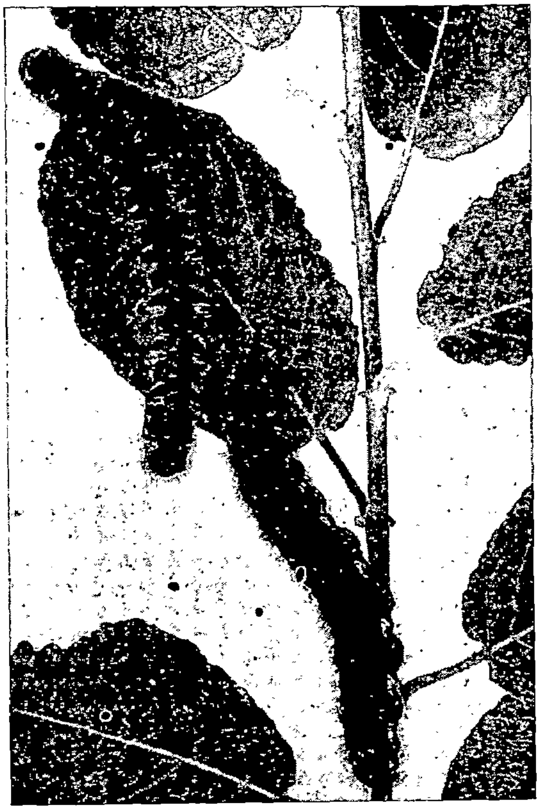

Fig. 1. Full-grown larvæ of *Lasiocampa quercus* L. Upper, normal yellow-brown colour; lower, melanic larva

however, of forty-six moths released, forty-four typical and two form *olivacea*, one *olivacea* was the only moth left after 2 hr. This suggests a very large visual selective advantage for the recessive dark mutant. Predation was so intense that few females could be seen at the end of a day, and the following year, in 1958, 134 larvæ only were found in a week compared with more than two thousand in a few hundred square yards during searching for 24 hr. in 1956 on precisely the same area.

Male eggars were also taken on the wing by the gulls and we observed swifts (*Apus apus*) catching them in numbers as well as wheatears (*Oenanthe oenanthe*). To us the melanic males were much more difficult to follow in flight than male f. *typica*. This was probably due to the absence of yellow bands, apart from their black colour (Fig. 2). We were also able to examine the 'feathering ground' of a pair of merlins (*Falco columbarius*) which were feeding extensively on the male moths. No melanic wings were present among the five dozen wings collected.

The dark mutants are to-day found throughout the industrial Yorkshire moors. Near Wallasey in Cheshire, form *olivacea* also occurs in about 5 per cent of the population, but here it has a one-year life-history[15]. In Caithness, northern Scotland, it constantly recurs in the population but is not so dark as elsewhere. In the rest of Britain it is a very rare mutant. Near Brandenburg in East Prussia, a similar or identical black mutant to f. *lurida* occurs near the estuary of the River Haval, and it is stated that it constitutes 100 per cent of the population, forming a local race[16]. 100 per cent of the caterpillars bred from this stock were also of the black form.

We have been able to collect further evidence on the spread of the recessive melanic in Britain. W. E. Collinson[17] has studied this insect in Yorkshire since 1936. He has observed the increasing frequency of the melanics which at that time formed about 1 per cent of the population. He has noted that the average colour of the typicals is getting steadily darker in this population, and he has observed the gradual darkening of the dark forms during the past twenty years. Moreover, he has recorded violent fluctuations in population size.

In 1957, I released 693 marked males and, using assembling traps placed over a square mile, recaptured 33 in a sample of 478 caught on subsequent days. This gives an approximate total male population of 10,000 for the peninsula of moorland on which I was working. There had taken place, therefore, a very high mortality-rate from the prodigious larval population of the previous year, 1956, when they swarmed in their thousands. A random sample of 311 cocoons picked up suggested the following pupal death-rate alone, regardless of late-larval mortality:

(1) Normal hatching		43
(2) Magpie predation. These have been observed to feed upon the pupæ in winter		81
(3) Disease. Virus and fungi. Unknown causes		170
(4) Parasites. Living solitary Ichneumonidae larvæ (1948)	4	= 17
Hatched Ichneumonidae	13	

This reflects a pupal mortality-rate of approximately 86 per cent. Of the total pupal population, therefore, 26 per cent were eliminated due to visual predation by magpies, and here it must be recorded that the *black* larvæ produce *black* cocoons, which are much more difficult to see than those of the typicals. Unfortunately, I was unable to recognize the differential predation on the cocoons because of bleaching.

We have then a situation in which two recessive melanic genes are spreading through a population. One controls larval colour, which is also reflected in the colour of the cocoon. The other is responsible for imaginal coloration. It seems that the genes for both are partially linked both in the Yorkshire and Cheshire localities. In Caithness, where *L.* f. *olivacea* forms a proportion of the population, the black larvæ do not occur[14]. The same situation is found in restricted areas in Holland and Denmark[18]. On

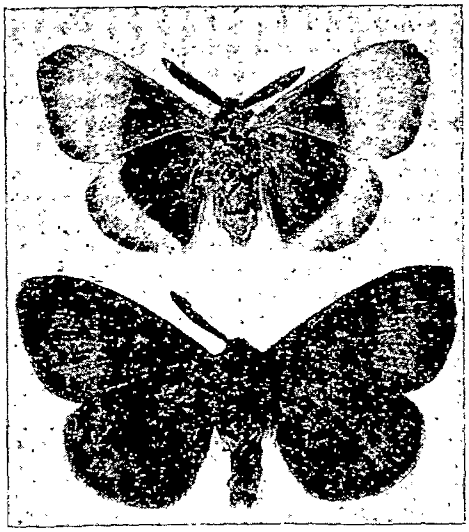

Fig. 2. *Lasiocampa quercus* L. f. *callunae*. Undersides of two males. Upper, f. *typica*; lower, a recessive melanic *lurida* Cockayne

the other hand, in Prussia there is evidence that a local population exists of black moths with black larvæ, though this is doubted by Cockayne[14].

We have worked on one other species in which larval and imaginal melanism is associated, the only other example known to me. *Arctia caja* L., the garden tiger moth, normally has crimson hind-wings which are only displayed on attack. There is a variable brown hind-winged form, *brunnescens* Stattermayer, which is the heterozygote of an all-black individual form, *fumosa* Hörhammer ; it is therefore incompletely dominant. All *fumosa* so far have been bred from black larvæ. The heterozygous larvæ are indistinguishable from those of typical *caja*, and this character, therefore, suggests that the same gene is responsible for both larval and imaginal coloration.

It will be of the greatest interest to see whether in the Yorkshire black eggars, natural selection, working on the cross-over value, will eventually bring the two genes for larval and imaginal melanism so close together that they act effectively as a single supergene. This would contrast with the situation in *Arctia* *ja*, where we feel confident that the association between black colour in larva and imago respectively has not been produced in this way. For here we are dealing with a very rare mutant, which has had no history of favourable selection necessary to bring two originally separate but advantageous genes together to form a controlling unit.

CÆSIUM-137 IN DRIED MILK

By D. V. BOOKER

Atomic Energy Research Establishment, Harwell

THE presence in human beings of traces of cæsium-137 derived from the world-wide fall-out of fission products from nuclear weapon tests was first reported by Miller and Marinelli[1] in 1956, and was also observed in human subjects in Britain by Rundo[2]. The main source of cæsium-137 in humans is probably cow's milk[3]. This article discusses the results of measurements of cæsium-137 and potassium in dried milk collected from different parts of the United Kingdom during 1957 and the first half of 1958. Measurements of the cæsium-137 and potassium contents of hay from four of these localities are also reported.

Samples of dried milk have been obtained from nine different areas in Great Britain, and studied for cæsium-137 and potassium content. Dried milk from one area has been studied since early in 1955, while most of the remaining samples were collected between April 1957 and June 1958. Table 1 gives the details of the factories, milk-collecting areas, the type of dried milk sample and the villages from which samples of hay were collected.

Estimation of Cæsium-137 and Potassium

Gamma-scintillation spectrometry was used for estimating potassium and cæsium-137 in dried milk with the aid of a sodium iodide crystal 3 in. diam. × 3 in. high with a photomultiplier and a five-channel pulse-amplitude analyser. Cæsium-137 was estimated from the 0·662-MeV. gamma-ray emitted by its short-lived daughter barium-137-*m*[4] ; potassium-40 occurs naturally in potassium and emits a gamma-ray of 1·46 MeV.[4]. Counting rates in the two photopeaks from a 2-kgm. sample of dried milk were compared with those from a similar standard sample of dried milk containing additional standardized cæsium-137 and another sample containing added potassium. A few dried-milk samples of only 500 gm. weight were measured with less accuracy.

The activity in hay samples was measured with the co-operation of Dr. J. Rundo of the Health Physics Division, Atomic Energy Research Establishment, using a gamma-spectrometer designed for monitoring the human body. This instrument utilizes four sodium iodide crystals 4 in. in diam. × 2 in. high. Counting rates were observed on a 100-channel pulse-amplitude analyser, and were compared with those from a sack of hay containing added standard cæsium-137 sources, and a sack with potassium chloride added. The hay, which was harvested

in the summer of 1957, was measured in July 1958. This delay allowed the zirconium-95 which has a radioactive half-life of 65 days to decay by a factor of about fifty. At this time the gamma-rays of about 0·75 MeV. from zirconium-95 and its daughter niobium-95[4] did not mask the peak at 0·662 MeV.

Cæsium-137 and Potassium in Dried Milk

The cæsium-137/potassium ratio in dried skimmed milk manufactured in Frome, Somerset, has been plotted in Fig. 1 for the period 1955–August 1958; the results to January 1957 have already been published[5]. Fig. 2 gives the results for the cæsium-137/potassium ratio in dried milk from other areas. The measurements show that there is little, if any, variation in the potassium content of dried milk either with time or location. The average values obtained are 15·4 gm. potassium per kgm. dried skimmed milk, and 11·3 gm. potassium per kgm. dried full-cream milk. The probable error of counting on these measurements is ± 0·3 gm. of potassium per kgm. of dried milk. On the cæsium-137/potassium ratio the probable error of counting is ± 2 μμc./gm.

From Figs. 1 and 2 it is seen that there is an apparent seasonal variation in the cæsium-137/potassium ratio. The decrease in the winter may be due to the change in the feeding habits of cows during winter, when they are given supplementary food. Samples from all areas show an increase in the cæsium-137/potassium ratio in June 1958. The rise at this time of year is associated with cows going out to pasture in the spring; but the levels observed are enhanced by the higher than usual rate of fall-out at this time from nuclear test explosions[6]. In the only area from which samples have been measured beyond June 1958, it seems that the cæsium-137/potassium ratio reached a maximum in July 1958.

Average values of the cæsium-137/potassium ratios have been taken for each of the eight areas where results are available from April 1957 to April 1958. Samples collected in late October and November have been excluded (see next section). The average ratios have been plotted against the average annua rainfall in inches for each area in Fig. 3. There is an apparent correlation between the cæsium-137/potassium ratio in dried milk and the annual rainfall. T slope of the line in Fig. 3 gives a value for the rati

$$m = \frac{\text{Cs-137/K ratio in milk } (\mu\mu\text{c./gm.})}{\text{annual rainfall in inches (in./year)}}$$

For the United Kingdom the value of m was 1 for the period April 1957–April 1958. A simil correlation between the cæsium-137/potassium rati in milk and the annual rainfall has been observe by Anderson[3] in the United States, with values o m of 1·9 and 0·7 for two different parts of the United States.

Effect of the Windscale Accident

Inspection of Figs. 1 and 2 shows that dried milk from all collecting centres south of Windscale (Buckingham, Carmarthen, Driffield, Frome and Garstang) showed an increase in the cæsium-137/potassium ratio for the first sample manufactured after October 10, 1957, while the other samples (Carlisle, Colerai and Mauchline) showed a decrease in the rati. The largest increase, of 95 μμc./gm., was in the dried milk from Garstang (the significance of these measurements of the cæsium-137 content of dried milk can be judged from the recommendations regarding the permissible intake in emergencies made to the Medical

search Council by the Council's Committee on otection against ionizing radiations (*Brit. Med. J.*, the press)), which is the station nearest Wind-ale, and is in the line of the plume of activity ich was released in the accident[7,8]. Garstang is out 70 km. from Windscale.

Mayneord *et al.*[9] have studied milk from Cardigan-ire during the period of the Windscale incident, and ve shown that the cæsium-137/potassium ratio creased from 80 μμc./gm. to more than 300 μμc./gm. day or two after the accident. By early November the ratio had decreased to about 150 μμc./gm., which is similar to the result of 107 μμc./gm. given in Fig. 2 for Carmarthen milk dried on November 5.

Using figures quoted by Booker[10] for the ratio of iodine-131 to cæsium-137 activities in herbage near Windscale, and the figures for the deposition of iodine-131 on herbage in North Lancashire, the deposition of cæsium-137 in the Garstang area can be estimated as 15 mμc./sq.m. of herbage. This corresponds to an rease of about 100 per cent on the previously isting cumulative cæsium-137 fall-out in this area rom distant bomb tests[6,11]. (Gustafson *et al.*[12] have easured the cæsium-137 content of soil from Braidwood, Illinois, which was collected in October 1957. They find 14·3 mμc. of cæsium-137 per sq.m. of soil from an area which has approximately the same rainfall as Garstang.) However, the cæsium-137/potassium ratio in dried milk from Garstang in June 1958 was as low or lower than that in dried milk from other areas. These facts are consistent with the hypothesis that most of the cæsium-137 which appears in dried milk comes from direct fall-out on the herbage and little from the soil. A similar conclusion was tentatively reached by Anderson[3].

Cæsium-137 and Strontium-90 in Hay and Milk

Hay from the 1957 crop was collected from four areas corresponding to four of the areas from which dried milk was collected. In each area a sample of hay was collected from each of five farms (in villages named in Table 1) and the samples were mixed. Table 2 gives a list of results of the cæsium-137 and potassium analyses of the hay samples. Also included are the results of the strontium-90 and calcium analyses performed on the hay samples by Bryant (private communication). The cæsium-137/potassium nd strontium-90/calcium ratios appear to be correated with each other and are of the same order of agnitude.

In Table 3 the cæsium-137/potassium and strontium-90/calcium ratios in the hay samples are compared with the same ratios in dried milk averaged over the period June–September 1957. The results for the strontium-90 and calcium in milk are quoted from Bryant *et al.*[13]. The ratio of the results for milk and hay have been included under the heading "Observed Ratio" (Comar *et al.*[14]). In using this term the following assumptions have been made: (1) The five farms from which the hay was taken were representative of all the farms sending milk to the collecting centres. (2) The grass cut for hay in the summer of 1957 was representative of the grass eaten by the cattle during June–September 1957 in respect of the cæsium-137/potassium and strontium-90/calcium ratios. (3) The cæsium-137/potassium and strontium-90/calcium ratios in the milk of the cows were representative of their feed at that time; that is, the milk was in equilibrium with the diet.

Of these assumptions (2) is probably the most doubtful, since the grass grown for hay would have a longer exposure to foliar uptake than that grazed continuously. During the summer of 1956, Bryant *et al.*[15] compared the strontium-90/calcium ratio in the accumulated growth of grass with that in which the grass had grown for only three weeks since the plot was last cut. This was done periodically during the summer at four stations. The accumulated growths had an average of only 28 per cent more strontium-90 per gm. of calcium than the new growth, which suggests that the error in taking accumulated growth would not be very large.

The assumptions are also supported by the fact that the Observed Ratios for the strontium-90/calcium ratios given in the last column of Table 3 lie not far outside the range of those reported from more carefully controlled experiments[14]. In particular, Morgan *et al.*[16] found an Observed Ratio of 0·09 for the strontium-90/calcium ratio in passage from diet to milk for a herd of cows at Sonning, Berkshire.

The Observed Ratio for the cæsium-137/potassium ratio varies considerably from region to region (from 0·6 to 1·2), but there is a clear indication that this ratio is near unity; this is very different from the Observed Ratio for the strontium-90/calcium ratio, which is about 0·1.

A qualitative comparison can be made with the cæsium-137/potassium ratios in human beings. Rundo (private communication) has found an average cæsium-137/potassium ratio of 45 μμc./gm. in individuals from Oxfordshire and Berkshire in the latter half of 1957. This result is not significantly different from the ratios in hay and milk from Frome, which has a rainfall similar to that in Berkshire. A full study of the sources of cæsium-137 and potassium in human diet would be needed to obtain an Observed Ratio, but it appears that the discrimination factors are again much nearer unity than those observed with the strontium-90/calcium ratio.

Summary

Measurements of the cæsium-137/potassium ratio in dried milk and some corresponding results for hay have been obtained for the period 1957 and the first half of 1958. In dried milk from Driffield, which has a relatively low rainfall, the ratio in the summer of 1957 was 25–30 μμc. of cæsium-137 per gm. of potassium, and dropped to 10–15 μμc./gm. in the winter. Dried milk from Carmarthen, a high-rainfall area, showed ratios of 60–70 μμc./gm. and about 40 μμc./gm. in summer and winter respectively. The decrease in the ratio in the winter may be due to the change in feeding habits of cows, which are given supplementary food in winter. A large increase in the ratios in dried milk from all areas was observed in June 1958 and is associated with a larger than usual rate of fall-out in May 1958 and subsequent months. The average cæsium-137/potassium ratio in dried milk in μμc./gm. for the period April 1957–April 1958 is shown to be numerically equal to the average annual rainfall in inches in the area from which the milk was collected. The effect of the Windscale accident on the cæsium-137/potassium ratio in dried milk is shown to have been temporary. The cæsium-137/potassium ratio in human beings in late 1957 was about the same as that in dried milk from an area having a similar rainfall.

RADIOACTIVITY OF SOILS, PLANT ASHES AND ANIMAL BONES

By SIR ERNEST MARSDEN, C.M.G., C.B.E., F.R.S.*

Department of Physics, Institute of Cancer Research: Royal Cancer Hospital, London, S.W.3

ATTENTION has been directed by Turner, Radley and Mayneord[1] to the large variation in naturally occurring α-ray activities of foodstuffs and tissues. While at present there is little direct evidence as to biological significance, the subject is of sufficient interest to make it desirable to record some recent observations, at the Institute of Cancer Research, made possible by the kindness of Prof. W. V. Mayneord in making available to me apparatus developed for such measurements.

(1) The first observations concern the relative activities of bones of sheep, cows and of their offspring. It had been noticed from tests in New Zealand that the bones of calves and lambs were low in activity compared with those of adults, and, thanks to the co-operation of Dr. C. P. McMeekan of the Ruakura Animal Research Station, New Zealand, bones were made available by air-mail of a cow and a ewe and of their new-born offspring. The mother animals had been grazed on pasture grown on soil of α-activity 8×10^{-12} c./gm. The results are given in Table 1.

These figures indicate an activity of the bones of the offspring only 10 per cent of that of the mothers and with relatively less thorium. The capsuled samples of bone ash from the mothers have shown an increase in activity of the order of 15 per cent in the three months following equilibrium with radon, etc. These increases are under long-period observation which will be reported later. Such measurements are of interest in comparison also with similar observations on many other bones of cows and sheep and of pastures, and apart from recovery of polonium there is the possibility that mesothorium is taken up relatively more readily than radiothorium. The average activity of a large number of such bones was about 5×10^{-12} c./gm. ash (max. $1\cdot4 \times 10^{-11}$), but in the case of three Suffolk sheep, killed and dissected in 1921 by Dr. J. Hammond, the average activity as now measured was only 7×10^{-13} c./gm. ash, with 10 per cent contribution from thorium products. This smaller activity may be due to decay of mesothorium and products (half-life 6·15 years) or may possibly be due in part to lesser use of superphosphate fertilizers at that time.

Table 1. ACTIVITY OF BONE ASH (C. PER GM.)

		Total α-activity	Approximate contribution of thorium products (per cent)
Mother cow	Femur shaft	$4\cdot8 \times 10^{-12}$	50
New-born calf	Femur shaft	$5\cdot8 \times 10^{-13}$	10
New-born calf	Femur head	$5\cdot2 \times 10^{-13}$	10
Mother ewe	Femur shaft	$4\cdot8 \times 10^{-12}$	40
Mother ewe	Femur head	$4\cdot0 \times 10^{-12}$	30
Lamb	Whole femur	$4\cdot8 \times 10^{-13}$	15
Lamb	Whole tibia	$4\cdot0 \times 10^{-13}$	14

(2) The second set of observations relate to the possible influence of the superphosphate on plant and animal uptake of radioactivity. Samples of rock phosphates of various origins were collected and Table 2 gives the activity of the particular samples.

It has been suggested to me by an officer of the United Kingdom Geological Survey that the activity of fossil guano arises from fixation by the phosphate of uranium from sea spray through the ages, but the

---

* Present address: Government Buildings, Wellington, C.1, New Zealand.

Table 2. TOTAL α-ACTIVITY (c./gm.)

Phosphate rock (Florida)	$2\cdot2 \times 10^{-10}$	
Ocean Island	$2\cdot1 \times 10^{-10}$	
Morocco	$2\cdot0 \times 10^{-10}$	
Nauru	$1\cdot75 \times 10^{-10}$	(*c.* 10 per cent)
Makatea	$1\cdot4 \times 10^{-10}$	
Christmas Island	$5\cdot5 \times 10^{-11}$

Peruvian phosphate (old guano)	$4\cdot5 \times 10^{-12}$	(< 10 per cent)
Peruvian phosphate (recent guano)	8×10^{-13}	

activity of Peruvian fossil guano does not fully confirm this. It is hoped to collect further samples which may provide information on this question.

It may be interesting to consider the effects on foodstuffs and animal bones of the growing use of superphosphates, a world increase of some 2½ times in the past 20 years and 10 times in the past 40 years. According to statistics from the Organization for European Economic Co-operation, approximately one million tons of superphosphate are used in the United Kingdom each year, and approximately 850,000 tons of basic slag and their content of uranium are added to the soils annually. In the United Kingdom at present, phosphate from Morocco is largely used, in New Zealand from Nauru—both active sources. This active material may be taken up by the roots into the plant or in the case of top-dressing of pastures it may, pending sufficient rainfall, remain on the leaves as dust to be consumed by grazing animals. Both these effects have been observed in the samples collected for test in the present experiments, but they were not laid out or planned with this particular type of test in view, and the quantitative aspect is influenced by varietal differences in uptake, for example, different strains of ryegrass. For plants grown in the same soil varietal differences are in general about as important as species differences, with Brazil nuts as an important exception. On average soils, plant ash shows results of the order $1\cdot6 \times 10^{-12}$ c./gm. Whole wheat and bran give results of this order also, but somewhat less and with significant varietal differences. Similarly, with the exception of such places as Devon, soils in general do not vary so much from place to place as one might expect from the activities of the parent rock material, and a general figure of 8×10^{-12} c./gm. may be used. The uptake by plants from soils is, however, governed more importantly by other factors.

Grass had been collected by the New Zealand Soil Bureau from six farms in Taranaki, New Zealand, all on andesite soil of activity approximately $3\cdot5 \times 10^{-12}$ c./gm. During the past ten years, two farms had been heavily top-dressed with superphosphate, two moderately and two received none. My measurements showed no very significant differences in activity of the grasses, especially when differing grass compositions are taken into account. More definite tests will be undertaken. In another case pasture was collected from a high-production test plot and the ash proved to have an activity of $1\cdot6 \times 10^{-11}$ c./gm. On further inquiry it was learned that the plot had been top-dressed a week or so before cutting and subsequent samples from the same plot, although at a different season, gave a value only one-tenth of this amount.

To enter into detailed description and discussion of all the results obtained would be beyond the scope of this article. Two important cases, however, are worthy of mention. The first is the soil covering of Niue Island in the Pacific. This is probably a volcanic ash shower material. Its α-activity is of the order of 7×10^{-10} c./gm., that is, some ninety times that of normal soils and with little contribution from the thorium family. By chemical analysis, kindly conducted at Woolwich, a figure of 60 p.p.m. uranium was obtained, but this would account for only about one-fifth of the activity. Qualitative α-pulse analyses conducted at Harwell indicate a major contribution of thorium-230 (ionium) and also, but less definitely, the possibility of an abnormally high uranium-235/uranium-238 ratio. If either or both of these results are corroborated, it would have very important geological significance. A study of activities of plants, bones of animals and humans of this Island will also be made shortly.

The other remarkable result is the large α-activity of slow-growing mountain pastures in Wales, Cumberland and Durham, particularly the first-mentioned. For these samples, along with many others and valuable co-operation and advice, I am indebted to Dr. Scott Russell, of the Agricultural Research Council Radiobiological Laboratory, Wantage.

At the end of the first month after ashing, the α-activity of one particular sample of Welsh grass ash was 8×10^{-11} c./gm., which rose 2½ months later to $1\cdot7 \times 10^{-10}$ c./gm. Except for the relatively small contribution of thoron as measured one might have attributed this to absorption from the soil of mesothorium and subsequent growth of radiothorium. It is hoped to secure α-pulse analysis scans of these remarkable plant ashes, also to study the uptake of uranium, radium and thorium by slow-growing plants on calcium-deficient soils and in different soil and climatic conditions. It should be noted that the last-mentioned figure of activity is greater than that of superphosphates although I am assured that no fertilizer was used.

I wish to express my appreciation to Prof. W. V. Mayneord and his staff for facilities placed at my disposal and for valuable discussion and suggestions.

---

CONTAMINATION BY EXTRA-TERRESTRIAL EXPLORATION

AT the instigation of the International Council of Scientific Unions, an *ad hoc* committee was set up in April 1958 to investigate the problem of contamination by extra-terrestrial exploration. The committee consisted of: Prof. Marcel Florkin (convenor), Laboratoires de Biochimie, Université de Liège; Dr. J. Rösch, Observatoire du Pic-du-Midi, Bagnères de Bigorre, Hautes-Pyrénées (representing the International Astronomical Union); Prof. J. Bartels, Geophysikalisches Institut der Universität, Göttingen (representing the International Union of Geodesy and Geophysics); Dr. Donald J. Hughes, Brookhaven National Laboratory, N.Y. (representing the International Union of Pure and Applied Physics); Dr. P. Alexander, Chester Beatty Research Institute, Royal Cancer Hospital, Fulham Road, London (representing the International Union of Biological Sciences); Prof. W. O. Fenn, School of Medicine, University of Rochester, N.Y. (representing the International Union of Physiological Sciences); and Prof. J. Roche, Collège de France, Paris (representing the International Union of Biochemistry). Prof. P. Swings, Institut d'Astrophysique, Université de Liège, and Prof. H. C. Van de Hulst, Sterrewacht, Leyden, were present as observers. To ensure wide regional representation the convenor asked for a chemist from the U.S.S.R. to act as representative for the International Union of Pure and Applied Chemistry. Unfortunately, it proved impossible for this to be arranged.

At the second meeting of the Committee, held at The Hague during March 9–10, the following summary recommendations were passed:

The Committee on Contamination by Extra-terrestrial Exploration was established in 1958 by the International Council of Scientific Unions to meet once to find out if the problem of contamination of extra-terrestrial objects by space vehicles represents a real problem. The report of this meeting, which was held in May 1958, was that in the Committee's view there is a real possibility that early experiments might spoil subsequent research. The Committee therefore proposed to the International Council of Scientific Unions that a code of conduct be drawn up for space research with particular reference to the allocation of priorities and sequences of different experiments. The Committee stressed that such a report would require active participation by experts, especially from the field of rocket technology. The International Council of Scientific Unions accepted this recommendation, and at its general meeting in Washington in October 1958 asked the Committee on Contamination by Extra-Terrestrial Exploration to hold a second meeting. At the same time the International Council requested the National Academies of the U.S.A. and the U.S.S.R. to assist the Committee with experts in rocket technology and with prepared documents. The Committee at its second meeting held at The Hague in March 1959 was able only to start its assigned task because the complexities of the problem made it impossible for the necessary detailed technical assistance to be available.

In the interval between the first and second meetings, a Committee on Space Research has been formed by the International Council of Scientific Unions to co-ordinate world-wide space research, and this new body enjoys the support of the American and Russian Academies. The Committee on Contamination by Extra-terrestrial Exploration feels that the detailed functions proposed for its second meeting form an integral and important part of the duties of the Committee on Space Research, and at this meeting the Committee confined itself to the general formulation of the problem and review of its initial report, which has been slightly modified.

General Principles

(1) Space research offers a challenge and opportunities which should appeal to the most imaginative minds. The greatest encouragement must be given to novel and unconventional approaches, and no proposal should be sanctioned which would hamper the experimenters' freedom of action unless there are compelling reasons. On the other hand, equally imaginative thinking is required when considering possible complications which can follow a particular type of experiment. Surprises are certain, and unlikely possibilities must be borne in mind when dealing with the problem of contamination, which is better defined as the problem of reducing the risk whereby one experiment may spoil the situation for other subsequent inquiries. The question of deciding whether such a conflict is likely to arise can best be dealt with by a committee or working group engaged in planning, or advising on, scientific experiments.

(2) Ideally, scientists should be asked to inform the Committee for Space Research as early as possible of each space experiment which is envisaged and of the methods to be used in its execution. The Committee on Space Research is broadly based and contains scientists from all disciplines; it is thus able to see much more clearly than the space research specialists possible conflicts introduced by such experiments and may be able to suggest ways of overcoming these difficulties.

(3) There are a number of obvious and necessary experiments which are bound to be done, and here the Committee on Space Research working group dealing with experiments may be able to suggest priorities. While it may not be possible to avoid all types of contamination, a proper sequence can ensure that the collection of data is not thereby hindered. For example, the Committee on Contamination by Extra-terrestrial Exploration recommends positively that no 'soft' landing, which requires the release of large quantities of gases, should be made on the Moon until experiments have been successfully carried out—or at least all reasonable attempts made—to determine the nature of the Moon's atmosphere.

(4) In view of the great uncertainties which face space research, all operations which are not capable of conveying meaningful scientific data are to be discouraged even if they do not appear to carry with them a known source of contamination. Risks with the unexpected must be taken, as otherwise no space exploration is possible; but such risks must be justified by the scientific content of the experiment.

Contamination endangering Physical and Chemical Studies

(1) *The Moon's Atmosphere.* The Moon's atmosphere contains only a small amount of matter (it is estimated at less than 100 tons) and is therefore extremely vulnerable to contamination. The release on the surface of any amount of volatile material (having a molecular weight greater than 60) within this range of magnitude, such as might be given off from explosions for marking purposes or to slow down the vehicle for 'soft' landings, is likely to remain on the Moon. Another factor which a change in the lunar atmosphere might bring about is an upset in the thermal equilibrium, and careful computation will be required before the magnitude of this effect can be assessed.

The release of any chemical marker on the surface of the Moon is therefore objectionable if it involves tons of material. If it has to be done, a flare releasing material quite unlike that normally present in the lunar atmosphere should be used, so that in subsequent investigations it can be clearly recognized as a contaminant introduced by man. Both in this connexion and because of increased ease in detection, a flare produced by sodium should be considered for this purpose. The sodium *D* lines could be detected at low intensities if a monochromator is used to cut out scattered light of other wave-lengths. Probably the quantity of material required to be visible through telescope, though not to the naked eye, would be isufficient to cause serious contamination of the tmosphere.

The possibility that a flare of this type might isturb the lunar atmosphere, due to the ionization f the sodium atoms by sunlight, has been considered, ut such an effect is unlikely to persist for long eriods.

From the foregoing it is clear that detailed exploraon can very easily modify the lunar atmosphere, hich should, if at all possible, be studied spectroopically from either Earth or Moon satellites before ndings are attempted. An accidental hit by a vehicle which has failed to go into orbit would probably not be serious, since the surface of the Moon ust occasionally be subject to bombardment by avy meteorites and the possible release of trapped es by impact will not therefore cause a departure om natural conditions.

(2) *Moon dust.* The chemical composition of the dust is of the greatest interest to a wide range of sciences. Knowledge of changes of composition at different levels would also be informative, but may be difficult to interpret since bombardment by meteorites is likely to disturb the dust. For this reason mixing of some of the dust by rocket impact is unlikely to result in loss of information.

The suggestion has been made in the recent scientific literature that there are unstable structures of a high free-energy content (that is, containing a high concentration of free radicals) on the Moon, which may be caused to react explosively on coming nto contact with organic substances from the Earth. The suggestion has therefore been made that great are be taken to exclude organic substances from pace-vehicles likely to impact on the Moon. The Committee does not support the view that such a hazard exists, since such free radical structures would be triggered off by any impact which caused intimate mixing. Meteorites or solar corpuscular radiation would act as a fuse and initiate an explosive chain-reaction. The man-made object would do no more harm in this respect. The possibility that valuable information concerning cosmic dust may be lost by disturbing the surface of the Moon has been considered but is unlikely to be serious. Analysis of Moon dust can only provide a very incomplete picture of cosmic dust, because many of the constituents will be volatilized by solar radiation.

(5) *Radioactivity.* A serious danger of altering the Moon's dust will come from nuclear explosions. These will release fission products which under the conditions of extreme vacuum will enter the Moon's atmosphere and be rapidly distributed. These radioactive atoms will be in a highly reactive form and on coming into contact with Moon dust may form involatile compounds. In this way the whole surface of the Moon may acquire additional radioactivity which may interfere with subsequent radiochemical analyses that could be of the greatest value, in particular for problems relating to the history of the Moon. The explosion of a fusion device is likely to be more serious than that of a fission bomb, since the former will give rise mainly to volatile radioactive products, notably tritium, whereas the bulk of the volatile fission products are rare gases which will not combine with the Moon dust. However, the range of the small particles by which fission bomb activity is spread is likely to be very great on the Moon, and a serious danger of contamination would undoubtedly arise.

Although the relative extent of the contamination of the planets from a nuclear explosion would be very much smaller than in the case of the Moon, it may none the less be sufficient to interfere with detailed radiochemical analyses under certain conditions. Also the effect of introducing radioactivity on another planet where there may be entirely different levels of background radiation from those found on Earth could greatly influence any form of life found there. Although the objections against nuclear explosions on Mars and Venus may not be as compelling as in the case of the Moon, they are nevertheless well justified until more information is available.

Biological Contamination

Recommendation for immediate action. The sterilization of space-vehicles to prevent the spreading of spores and other terrestrial micro-organisms in the solar system is likely to present a number of technical problems that may not be easy to solve. The Committee on Contamination by Extra-terrestrial Exploration suggests that the Committee on Space Research initiates a study immediately of the methods by which the inside of space vehicles can be sterilized, bearing in mind the presence of delicate instruments that must not be damaged. As soon as possible, methods should be published by which this can be achieved, and it should be urged that all space probes be sterilized in this way. Although the Committee on Contamination by Extra-terrestrial Exploration feels that the possibility that life can persist on the Moon is sufficiently remote to justify being neglected, all Moon probes should be sterilized so that the difficult techniques of sterilization may be worked out in practice.

The outside of space-vehicles need not be sterilized, since exposure to the unfiltered solar radiation during flight will destroy all micro-organisms which have settled on the shell. The need for sterilization is only temporary. Mars and possibly Venus need to remain uncontaminated only until study by manned spaceships becomes possible.

(1) *Contamination of the Moon by living cells.* There is no reasonable possibility by which the introduction of cells such as spores or bacteria might give rise to life on the Moon of the same type (that is, containing deoxyribonucleic acid) as on Earth which might confuse later investigators. There are no cells on Earth which grow or multiply in the absence of water, and at the high vacuum of the Moon no water can exist on its surface.

(2) *Contamination of Mars and Venus.* There is a possibility of biological contamination of these planets, since there is a reasonable probability that the conditions on Mars are such that some terrestrial organisms might grow. Carbon compounds, light for photosynthesis and probably water and nitrogen are all available. It is therefore of the greatest importance that space-vehicles should not land either accidentally or deliberately on Mars (and possibly also Venus) unless all precautions have been taken to exclude living organisms from them. Otherwise the most challenging of all planetary studies, that of extra-terrestrial life, may be put in jeopardy. The same precautions in regard to the development of complex molecules which have been dealt with in respect of lunar contamination in paragraph 4 below apply equally to both Mars and Venus.

(3) *Panspermia hypothesis.* The suggestion that Moon dust might help in evaluating the hypothesis

that dissemination of life in the cosmos occurred by transport of forms of life in the cosmic dust must be rejected, because solar radiation (in a high vacuum) would decompose 'biospores' just as it decomposes cosmic dust. The possibilities by which a spore might travel through space inside meteorites involve so many improbabilities that they do not justify special consideration at this stage.

(4) *Development of complex molecules*. The basic problem concerning the origin of life is how complex molecules (on the Earth they are based on carbon) came to be built up and become replicated. It is conceivable that the interior of the Moon dust may provide some valuable clues in this direction. It is not beyond the bounds of possibility that some 'pre-life' processes may be occurring on the Moon, and these may be similar or different from those which have taken place on Earth. If there are such processes, then the introduction of 'foreign' macromo cules from the Earth may cause a serious upset in t lunar processes. Macromolecules from the Ear might under lunar conditions act as templates a provide new foci for 'pre-life' growth. If such even were started indiscriminately all over the Moon, t pattern might be distorted. It is important emphasize that living cells are not envisaged for th process, and that in this connexion a dead bacteriu from an aseptic rocket would be as harmful as a li one. The occurrence of any such growth reactio is remote and does not justify the imposition of an irksome restrictions on lunar exploration, but whe reasonably possible it should be borne in min A simple precaution against endangering futur studies might be to limit the areas of landings on th Moon and thereby to localize the effects—if any—of terrestrial templates.

OBITUARIES

Sir Owen Richardson, F.R.S.

In Sir Owen Richardson, whose death occurred on February 15, Britain lost one of her most eminent physicists.

Owen Willans Richardson was born in 1879 at Dewsbury in Yorkshire. He won scholarships, first to Batley Grammar School, thence to Trinity College, Cambridge. He was soon absorbed in research among the famous company inspired by J. J. Thomson. By the age of twenty-two, the results of his first investigations had been published, and for more than thirty years there followed a flow of papers—attacking fundamental problems of the times—at a rate which can seldom have been exceeded.

Early at the Cavendish Laboratory, Richardson carefully observed the temperature variation of the saturation electron current from a hot platinum filament (at low pressure). From considerations of kinetic theory, he quickly developed a clear explanation based on the evaporation of conduction electrons through a potential barrier at the metal surface. He obtained the formula $i = AT^{1/2}(\exp(-b/T))$, agreeing with his experiments and related formulæ, derived, apparently, about the same time by J. J. Thomson and H. A. Wilson from thermodynamical arguments. About 1903 he was elected a Fellow of Trinity College and became Clerk Maxwell Student. He was awarded the London D.Sc. in 1904.

Throughout the first fifteen or so years of Richardson's career, phenomena of thermionic emission, in the broadest sense, retained a central position in his interests; they were complicated by the inadequate vacuum and cleaning-up techniques of the times. Largely by his efforts and those of his friend, H. A. Wilson, the thermionic emission was finally formulated by $i = AT^2(\exp(-b/T))$, which is scarcely distinguishable experimentally from the original formula. Although the electron gas concept of the conduction electrons became modified, ultimately, by Fermi–Dirac statistics and wave mechanics, the second equation, Richardson's Law, remains. The early developments are described in his book, "The Emission of Electricity from Hot Bodies", first published in 1916. For his work in thermionics, a term he himself coined, he was awarded the Nobel Prize in Physics in 1928.

While still at Cambridge, Richardson's thermionic investigations led to studies of ionic recombination, of the diffusion of hydrogen through palladium and platinum and to the theory of the diffusion of dissociated gas in solution and to other projects. He had great mathematical facility.

In 1906 he was appointed to the chair of physics at Princeton University. Papers followed on the pressure shift of spectrum lines, the gyromagnetic effect, the ratio of the charge to the mass of positive ions, the energy distribution of electrons emitted by hot bodies, which, with F. C. Brown, he proved to be Maxwellian. Work followed on the reflexion of slow electrons by metal surfaces, gravitation and electron theory, theory of dispersion and residual rays, diffusion of neon through hot quartz and various projects on problems related to the work function, including the heating and cooling effects accompanying thermionic absorption and emission with H. L. Cooke, the theory of contact e.m.f., thermo-electricity and the photoelectric effect. With K. T. Compton he played a large part in the verification of the Einstein photoelectric law. He made many pioneer studies, some in collaboration with C. J. Davisson, C. Sheard and others, on the emission and properties of positive ions from heated metals and salts. He may have been the first to observe the emission of secondary electrons by positive ion impact. He also wrote on the asymmetric distribution of electrons produced by X-rays passing normally through a metal plate, etc.

In 1914 Richardson returned to England to become Wheatstone professor of physics at King's College, London. His book, "The Electron Theory of Matter", based on his Princeton lectures, was first published in the same year. It takes its place as a landmark in the history of physics. It is a model of the *ab initio*, not too contracted presentation, which university students like and deserve. Papers followed on absolute photoelectric yields with F. J. Rogers; metallic conduction, photochemical action and (1916–17) spectroscopic researches with C. B. Bazzoni. Limiting frequencies in the spectra of hydrogen and helium for 800-V. electrons were observed at 950–830 A. and 470–420 A. and compared with Bohr's calculations. Further theoretical work on the gyromagnetic ratio followed. In 1924 he was appointed Yarrow research professor of the Royal Society, thereby being relieved of teaching duties. He began extensive investigations of the spectrum of molecular hydrogen with T. Tanaka, K. Das, P. M. Davidson, T. B. Rymer and others, and he himself made major contributions to the analysis of this most difficult of all molecular spectra. His book, "Molecular Hydrogen and its Spectrum", published in 1934, was based on his Silliman Memorial Lectures at Yale University. He retained interest in the H_2 triplet fine structures, on which he had unpublished high-resolution data, almost up to the time of his death. His last paper appeared in 1953; he had retired from the Yarrow professorship in 1944. Other work at King's College included an attempt, very early in the era of wave mechanics, to calculate the cold emission from metals under intense fields, and, in collaboration with H. T. Flint, interesting speculation concerning a least proper time.

Soft X-ray spectra of several metals were studied, especially with the late F. C. and Mrs. Chalklin. Extensive investigations of the emission of electrons during chemical reactions were undertaken, first with the late L. G. Grimmett and later with A. K. Denisoff. He acquired a splendid reflexion echelon for measurement of the wave-numbers and structure of the Lyman α line of H. He collaborated with W. E. Williams and J. Drinkwater in first measuring the wave-numbers and structures of the $H\alpha$ and $D\alpha$ lines to test the Dirac theory. Regrettably, a mysterious error crept into these observations. The results misled physicists until the Lamb–Retherford experiments. He made a notable study (1944) with the late Irena Gimpel of the reflexion of very slow electrons by copper, with apparatus earlier perfected by A. M. Crooker.

Richardson received honorary degrees of the University of Leeds (D.Sc.), St. Andrews and London (LL.D.); he was an honorary Fellow of King's College, London, and Trinity College, Cambridge. He was knighted in 1939. He was president of the Physical Society during 1926–28 and its honorary foreign secretary during 1928–45, which capacity included entertaining many distinguished foreign visitors.

There will be many who will recall his generous hospitality, and his first wife, the sister of H. A. Wilson, who was a most gracious hostess. He had a beautiful home with the finest English period furniture and a dazzling collection of paintings by Dutch and other old masters, fit for any national collection. About the house were several grandfather clocks, one in his library, by a contemporary of Thomas Tompion. They were wound once a week by the local clockmaker.

Sir Owen was a quiet and kindly man of few well-chosen words, but he had a keen sense of humour. He was exceedingly proud of his northern origins and could speak the Yorkshire dialect. His forebears of Dewsbury were manufacturers, in the trade of the district. One of his stories (generally true, with a good moral) concerned two of these individuals, engaged in the development of a machine for processing cloth. After much time and effort and failure in getting the machine to work, one remarked despondently to the other, "It wearnt go". After some thought, the other replied firmly, "It mun go!" The work proceeded. In due course the machine was perfected. It was called the Mungo machine.

Richardson was versed in botany and nearly took up this subject at Cambridge instead of physics. He kept a fine garden. About the outbreak of the Second World War he bought a large farm, some miles from his home at Alton, Hampshire, and supervised this for several years. He bought it as an investment, as a war effort, and, he said, to try and get back the fortune lost there by some of his ancestors who had migrated south to that part.

His two sons and a daughter and his second wife survive him. His elder son is professor of physics at Bedford College, London. E. W. Foster

Dr. W. H. Mills, F.R.S.

The sudden death of William Hobson Mills on February 22, at the age of eighty-five, deprived Cambridge chemistry of its last link with the nineteenth century. Mills went up to Jesus College from Uppingham in 1892, and took first classes in both parts of the Natural Sciences Tripos. After his election to a research fellowship in 1899, he went to Tübingen to work with von Pechmann, and there began his life-long friendship with N. V. Sidgwick. Upon his return to England he left Cambridge to become head of the Chemistry Department at the Northern Polytechnic in London, and during his ten years there he began the stereochemical work which was to gain for him an international reputation. He returned to Cambridge in 1912 as a Fellow of Jesus and demonstrator to the Jacksonian professor (then Sir James Dewar), and he remained there until his death.

Mills's achievements in the field of stereochemistry will always rank among the most powerful contributions made to the subject, for he had a flair for planning and carrying out a decisive experiment. By the synthesis and resolution into optically active forms of suitable compounds, he and his colleagues successfully demonstrated the non-linearity of carbon, nitrogen and oxygen in the oximes, the tetrahedral distribution of valencies in substituted ammonium ions and zinc complexes, and the planar configuration around 4-co-ordinated dipositive palladium and platinum. He played a great part in developing the steric theory to account for the optical activity of certain ortho-substituted diphenyls, and he later extended the idea of steric hindrance to free rotation to naphthalene, quinoline and benzene derivatives. Mills and Maitland, by their demonstration of optical activity in 1 : 3-diphenyl 1 : 3-di-α-naphthylallene, confirmed a prediction made fifty years earlier by van't Hoff and, as a writer in the "Annual Reports on the Progress of Chemistry" put it, "realized one of the ambitions of all stereochemists". Mills also made important discoveries in connexion with the chemistry of cyanine dyes and alkyl-substituted pyridines and quinolines.

Mills was elected to the Royal Society in 1923, and he received the Davy Medal in 1935; he was appointed to a personal readership in stereochemistry at Cambridge in 1931, and he was George Fisher Baker Lecturer at Cornell in 1937. Unfortunately, he could never be persuaded to publish the lectures and, indeed, throughout his life he seldom published anything but self-contained original papers. He was president of the Chemical Society during 1941–44. After his retirement, he seldom visited the laboratory, but he retained a wide interest in scientific matters, and his 1942 Pedler Lecture on "The Basis of Stereochemistry" anticipated much that has since been written on that subject.

No account of Mills's life would be complete without a reference to his extensive knowledge of the British flora and ornithology. He also had a long memory and a good knowledge of Cambridge history, and his excellence as a *raconteur* made him always entertaining company in the combination room of the College of which he was for nearly fifty years a Fellow, and during 1940–48 President. A. G. SHARPE

The Rev. H. H. Symonds

THE Rev. H. H. Symonds died on December 28, after a long and painful illness; by his death, the Council for the Preservation of Rural England, the corresponding body in Wales and the rural preservation movement as a whole have sustained an irreparable loss. He was a firm believer in the value and possibilities of national parks for the good of the community, and made this province especially his own. He was largely responsible for the establishment in 1935 of the Standing Committee on National Parks of the Councils for the Preservation of Rural England and Wales under the chairmanship of Mr. Norman (now Lord) Birkett. This became his absorbing interest and together with the late John Dower he took on the work of honorary drafting secretary which he carried out until 1952, when he asked to be relieved of the duties so as to enable him to devote his time to other urgent work in connexion with the North Wales (Hydro-Electricity) Protection Committee, of which he was chairman. To his labours in the field of national parks to rouse and sustain public interest may justly be ascribed the introduction of the National Parks Act and the establishment of the National Parks Commission. It was a great disappointment to him that his tenure of office as a National Parks commissioner—an appointment long overdue when it at last came—was ended so quickly and abruptly by the illness which caused his death.

Symonds was no sentimentalist. He was a very able, hard-hitting protagonist, respected by his critics and opponents and admired by his friends and supporters. He was possessed of ability and intellect of the highest order; he had the gift of making the obscure transparent and the difficult plain. We must esteem him for his unswerving fidelity to his principles and his fearless propagation of his views. It would have been a great reproach to Britain if national parks did not exist as an enduring and appropriate memorial to one who was so entirely devoted to their service. HERBERT GRIFFIN

Mr. Augustine Courtauld

MR. AUGUSTINE COURTAULD, son of Samuel Courtauld, of Courtaulds, Ltd., died after a long illness on March 3. From his Cambridge days he had been interested in exploration and had travelled in Greenland with J. M. Wordie, of St. John's College, now Sir James Wordie, and in the Sahara with Francis Rodd, later Lord Rennell of Rodd. During 1930–31 he was in Greenland as a member of Watkins's British Arctic Air Route Expedition, and during the winter manned alone the meteorological station near the centre of the ice cap. The difficulties of travel on the ice cap in the autumn had made it impossible to stock the station with sufficient food and fuel for two men, and Courtauld, at his own request, stayed there alone—a feat of personal heroism and endurance, quietly undertaken, which equals any in polar exploration.

Courtauld was not a scientist; his interests were literary, but he equipped himself as a surveyor to make himself useful on expeditions. He shared the leadership of a successful expedition in 1935 to the Watkins Mountains of East Greenland. The party climbed the highest mountain in the Arctic, since named by the Danes, Gunnbjørns Fjæld, 3,700 m.

L. R. WAGER

NEWS and VIEWS

Department of Scientific and Industrial Research Wolfe Award: Dr. L. Essen, O.B.E.

DR. L. ESSEN was recently presented by Lord Hailsham, Lord President of the Council, with the Wolfe Award of the Department of Scientific and Industrial Research, in the form of a cheque for £500. This is the first of ten annual Awards to be made, under the terms of a will, to the scientist who has made an outstanding contribution to the research work of the Department during the previous twelve months.

Dr. Essen, a senior principal scientific officer at the National Physical Laboratory, received the Award for his work on the establishment of an atomic frequency standard as a basis for the future standard of time. Although the first attempts to employ molecular and atomic frequencies as 'clocks' were made in the United States, Dr. Essen was the first to appreciate the vital importance of this earlier work as a possible basis for a new physical standard of time. The cæsium frequency standard that he designed is used to calibrate the quartz clocks at the National Physical Laboratory and to monitor the *M.S.F.* standard frequency transmissions. Valuable information has been obtained on the performance of quartz clocks, the propagation of radio signals, the periodic and irregular variations of the rate of rotation of the Earth, and the value of the present international standard of time in terms of a particular frequency of the cæsium atom. The unit of time provided by the present atomic frequency standard can be determined in a few minutes to an accuracy of 2 parts in 10,000 million. This figure of merit is ten times better than that recently announced from measurements, extending over three years, of the astronomical unit based on the period of the Earth's revolution around the Sun. The National Physical Laboratory standard has, in effect, been the time standard of the world for the past three years.

Iron and Steel Institute: Medals and Prizes

THE Council of the Iron and Steel Institute has awarded the following medals and prizes: *Bessemer Gold Medal for* 1959 to Prof. Bo Kalling, until recently director of research, Stora Kopparbergs Bergslags Aktiebolag, Sweden; *Sir Robert Hadfield Medal for* 1959 to Mr. Albert Jackson, technical adviser on steelmaking to the United Steel Companies, Ltd.; *Andrew Carnegie Silver Medal for* 1958 to Dr. P. Vasudevan, Department of Metallurgy, University of Manchester, for a paper on "The Kinetics of Bainite Formation in a Plain Carbon Steel" (*J. Iron and Steel Inst.*, p. 386; December 1958); his co-authors, Dr. L. W. Graham and Dr. H. J. Axon, were not eligible for an award; *Williams Prize for* 1958 to Mr. H. C. Child, research manager, William Jessop and Sons, Ltd., for a paper on "Vacuum-melting of Steels" (*J. Iron and Steel Inst.*, p. 414; December 1958); his co-author, Mr. G. T. Harris, was not eligible for an award.

Honorary Member

Mr. Arnold Hugo Ingen-Housz, president of the Iron and Steel Institute during 1957–58, has been elected an honorary member of the Institute. Mr. Ingen-Housz, who was born at The Hague, received his technical education at the Technical University of Delft, obtaining a degree in mechanical engineering in 1911. After working with Royal Dutch Shell and the municipality of The Hague, he joined the Koninklijke Nederlandsche Hoogovens en Staalfabrieken N.V. in 1917 as technical assistant to the founder of the company, Mr. Wenckebach, in the planning and construction of the Ijmuiden plant. On the death of the founder in 1924, Mr. Ingen-Housz became joint managing director of the company, together with Mr. Kessler. When Mr. Kessler died in 1945, Mr. Ingen-Housz assumed the position of president of the management board, and held that position until his retirement this year. When he became president of the Iron and Steel Institute in 1957, Mr. Ingen-Housz was the first overseas member to receive this distinction since the late C. P. E. Schneider, who served during 1918–20.

Royal Aircraft Establishment:

Mr. S. F. Follett, C.M.G.

Mr. S. F. Follett, who has been appointed deputy director (equipment) of the Royal Aircraft Establishment, graduated with first-class honours in engineering at the University of London. He served the Electrical Research Association on switchgear research during 1924–27, and joined the Electrical Engineering Department of the Royal Aircraft Establishment in 1927, where he was concerned with the application of electrical engineering to the aeronautical field, including electric power supply systems for aircraft, engine ignition work, early application of plastics, etc. He was appointed to Ministry of Supply headquarters as assistant director of instrument research and development (electrical) in 1946. In 1950 he was made director of instrument research and development, concerned with aircraft instruments, aerial photography and bomb-sights. He was made principal director of equipment, research and development in 1954 and, two years later, deputy director general. His former responsibilities were extended to cover armament and general mechanical accessory fields. He was appointed director general, Ministry of Supply Staff, British Joint Services Mission in Washington in 1956, and held this post until he took up his present appointment as deputy director of the Royal Aircraft Establishment.

Dr. A. G. Touch

Dr. A. G. Touch has been appointed senior superintendent of the Radio Department, Royal Aircraft Establishment, in succession to Dr. J. S. McPetrie (see *Nature*, 182, 768; 1958). After graduating at Oxford, Dr. Touch served under Mr. (now Sir Robert) Watson-Watt at the Air Ministry Research Establishment, Bawdsey Manor, in 1936, where he was engaged on early work on airborne radar. In 1940, he continued the development of airborne radars at the Royal Aircraft Establishment, but left in 1941 to join the British Air Commission, Washington, until 1947. On his return in 1947 he became superintendent of the Blind Landing Experimental Unit. In 1952 he was appointed deputy director of electronics, research and development (air) at the Ministry of Supply headquarters and, in 1954, became the director responsible for the development programme for radio and radar equipment for the Naval Air Branch and the Royal Air Force. In 1956 he was appointed director of electronics research and development (ground), responsible for the development of ground radar for the Army and the Royal Air Force. At the end of 1956 Dr. Touch carried out an independent investigation into the crash of a 'Vulcan' aircraft at London Airport, at the request of the Minister of Transport and Civil Aviation. After a year (1957) at the Imperial Defence College, he returned to his previous post.

Mr. R. J. Lees

Mr. R. J. Lees has been appointed head of the Instrument and Photographic Department of the Royal Aircraft Establishment in succession to Mr. C. N. Jaques, who has taken up an appointment with the British Joint Services Mission in Washington. Mr. Lees was educated at King Edward's School, Stourbridge, and was a major scholar of St. John's College, Cambridge. He obtained first-class honours in Part I and Part II (physics) of the Natural Sciences Tripos. He also obtained a first-class external degree in physics at the University of London. Soon after the outbreak of the Second World War he joined the Air Ministry Research Establishment, Dundee, to work on radar and, apart from a period during 1955–56 when he was director of scientific research in electronics at the Ministry of Supply, London, he continued at this Establishment, now the Royal Radar Establishment, Malvern, until receiving his present appointment. For the past two years he has been head of the Airborne Radar Department of the Royal Radar Establishment.

The Nature Conservancy

In an attractive booklet in which the illustrations are liberal and sometimes coloured, the Nature Conservancy describes its growth and development since its birth ten years ago (see also pp. 917, 935 of this issue of *Nature*). Besides maps showing the location of the many nature reserves which have been established, the booklet describes the organization of the Conservancy and the way it operates under the ægis of the Privy Council. Of the staff of about two hundred employed, rather more than one-third are scientists engaged in research or conservation. The remainder include land agents, wardens and estate workers, cartographers and administrative staff. Regional officers were first appointed to different parts of England and Wales in 1953. Among the professions and skills represented by the staff are soil analysis, diagnosis of herbage eaten by voles, construction of sluices, deer stalking, mathematical design of scientific experiments, tree-planting, interpretation of aerial photographs, procedure for making by-laws, extraction of minute animals from the litter layer in woodlands, negotiations for land acquisition, control of peat erosion on high moorlands, stomach analysis of seals, use of herbicides on vegetation between high- and low-water mark, mountain rescue, recording of vegetation changes on grassland, fixation of shifting sand dunes, and interception and arrest of deer poachers operating after midnight. The booklet (obtainable from the Nature Conservancy, 19 Belgrave Square, London, S.W.1, post paid 1*s.* 6*d.*) contains details of the public relations and educational work carried out by the Conservancy and is itself a model of how such publications should be produced.

Protection of the Shropshire Hills

The Minister of Housing and Local Government, Mr. Henry Brooke, has confirmed an order made by the National Parks Commission, establishing about 300 square miles in Shropshire as an area of outstanding natural beauty. The designated area includes the fine landscape around Church Stretton, with Caer Caradoc, the Long Mynd, the Stiperstones and the long ridge of Wenlock Edge, from which it extends north-east to take in the Wrekin and the Ercall. To the south-east, parts of the Clee Hills are included, and to the south-west the Clun Forest area on the Welsh border. Responsibility for preserving and enhancing the natural beauty of the landscape rests with the local planning authority, Salop County Council. Government grants can be made at the rate of 75 per cent toward the cost of treating derelict land, tree planting and preservation work. Grants are also available toward expenditure incurred in making agreements or orders for public access to open country and in appointing wardens. Designation does not of itself provide any additional right of access to private land.

Chinese Scientific Literature

The Lending Library Unit of the Department of Scientific and Industrial Research has started to collect Chinese scientific literature, and now receives regularly about 150 Chinese scientific and technical periodicals. The Lending Library Unit in London, which forms the nucleus of the new National Lending Library for Science and Technology, which will be set up at Thorp Arch, near Boston Spa, Yorks, in 1961, already has a large collection of Russian scientific literature, which is available to research, industrial and other organizations, through a loans service, and operates a scheme for the translation of Russian scientific literature, in collaboration with the U.S. National Science Foundation. This may possibly be extended in the future to include scientific literature from China.

Bulk Production of Silicon in Britain

Imperial Chemical Industries, Ltd., has brought into operation a large-scale development plant for the manufacture of high-quality silicon of semi-conductor grade. This remarkable material, which costs more than £100 per pound, has become of commercial importance during the past few years in the manufacture of semi-conductor devices, such as transistors, which are fast replacing conventional thermionic valves in many applications. The I.C.I. plant is operated by its General Chemicals Division on Merseyside. By the middle of this year capacity will approach 4,000 lb. per annum. Plans for much larger production are well advanced. Lump silicon, *p*-type, of resistivity greater than 200 ohm cm. is now available in quantity. Silicon in rod form, deposited direct from vapour and of exceptionally low boron content, is being produced in limited quantities in lengths of 24 in. and diameters up to 1 in. These rods are suitable for zone refining.

Smoking Habits

It often happens that investigators, particularly in the social sciences, must try to collect the information which they need by using questionnaires. One of the many problems that are apt to arise concerns the reliability of answers to questions which require an exercise of detailed and specific memory. Recently, the Tobacco Manufacturers Standing Committee issued a Research Paper (No. 2) entitled "The Reliability of Statements about Smoking Habits", by G. F. Todd and J. T. Laws (pp. 50; 1958). This should be consulted by anybody who has to try by questions to obtain factual information about habits or events covering any period in the past from a month or two to several years.

The authors show how statements about current smoking habits are generally reconstructed from a sort of 'mental picture' that the informant has of himself 'in his role as a smoker'. Changes in smoking habits are far more frequent than is generally thought to be the case, and so any information about them which refers to the past, based, as it must be, upon a general and personal assessment of current practices, is very likely to be in error. But the changes do not appear to be distributed in a random manner and, provided the sample groups investigated are large enough and the questions asked are answered seriously, so far as group tobacco consumption is concerned, information gained in this way is probably reasonably accurate in a statistical sense. For individuals, recall is frequently mistaken both as regards the amount and the kind of smoking carried on. Apart from the special topical interest of this study, it has wide methodological implications which ought to be considered by all users of questionnaires.

Bibliographies on Geology

Within recent years the United States Geological Survey has been very active in the publication of annotated bibliographies ranging over a wide spread of geological topics, many of them of world-wide interest. Among these works is a series of "Contributions to the Bibliography of Mineral Resources" (*Bulletin United States Geological Survey*, 1019*A-L*; 1954–58), which embrace separately published chapters reviewing the literature on the iron-ore resources of the world, on the world's quicksilver, titanium and nickel ores, and on the domestic distribution of magnesium salts, thorium and rare-earth deposits, salt beds, asbestos, and various industrial rocks. A second series of "Selected Bibliographies of Uranium Geology" (*Bulletin*, 1059 *A-E*; 1957–58) reviews the principal papers on uraniferous coal deposits, phosphorites, hydrocarbons, and uranium-bearing sandstones and igneous rocks in North America. Similar reviews of the international literature (including Russian works) on geophysics are published quarterly under the title "Geophysical Abstracts" (*Bulletin*, 1048, 1956; 1066, 1957; 1084, 1958); and another noteworthy compilation in the same category is "Bibliography of North American Geology", published yearly. A recently published bibliographical index to North American geology for the decade 1940–49 extends to 2,200 pages (*Bulletin*, 1049, 1957).

Apart from *Mineralogical Abstracts* (shortly to be published in a new format), British activity in geological bibliography has not of late been noteworthy, and for twenty years the only literature list covering Great Britain has been one compiled in the Library of the United States Geological Survey and published by the Geological Society of America. At the British Commonwealth Scientific Official Conference on Geology and Mineral Resources in 1948, it was resolved that each Geological Survey should produce an annual volume of abstracts covering its home ground. Most Commonwealth countries have now fulfilled this obligation, but there is not yet available any systematic compilation of abstracts covering the 300 or so papers on the geology of Britain published each year. In current international conversations on abstract journals in geology, it is to be hoped that this British domestic responsibility will not be overlooked.

Time Measurement

It will come as a surprise to many people who take their modern time services for granted to read that the first mechanical clock was made in the fourteenth century and that in earlier times the sundial and water-clock were the chief time-keepers. The Science Museum, South Kensington, has recently published the fourth edition of Part 1 of its Handbook of the Collection illustrating Time Measurement (pp. 60 + 12 plates. London: H.M. Stationery Office, 1958. 5*s.* 6*d.* net). Compiled by Dr. F. A. B. Ward, it traces the history of time measurement from its beginnings through the development of mechanical clocks and watches to chronometers. Chapters are devoted to electric clocks, including the Shortt free-pendulum and the synchronous motor clocks, to the quartz-crystal clock and to the atomic clock. Two chapters on chronographs and on various accessory mechanisms conclude the Handbook. Three hundred years ago, when the first pendulum clock was developed by Huygens, the maximum accuracy attainable was an error of ten seconds a day. To-day, the cæsium atomic clock has an error not exceeding one second in three hundred years, an improvement compared with Huygens's clock by a factor of one million. Indeed, the measurement of time is the most precise measurement of any physical quantity yet attained. This high accuracy is far beyond that required for civil purposes, and astronomers and geophysicists are likely to derive the most important benefits from the extreme accuracy now available. Those who are less interested in modern developments than in the history of science will welcome this descriptive Handbook for its account of the mechanical and electrical inventions which have contributed to the improvement of time-keeping.

Basic Biodynamics

In a recent publication, E. J. Kempf (*Ann. N.Y. Acad. Sci.*, 73 (4), 871; 1958) discusses current ideas on the interplay of genes and cytoplasm in relation to tissue and organ differentiation of multicellular organisms. After pointing out defects in existing explanations, he postulates six basic laws of biodynamics which he believes will "provide the biological sciences of genetics, cytology, embryology, biochemistry, physiology, psychology and sociology with a formulation of the basic natural processes involved in their special fields of investigation. These laws will clarify and facilitate the further development of secondary laws of the sciences of living behaviour". This somewhat extravagant claim is put forward in a singularly obscure and cumbersome style. Nevertheless, the paper contains a number of novel and stimulating ideas, and is worth close study.

Instruments in Industry

Evans Electroselenium, Ltd., Colchester Road, Halstead, Essex, has issued a series of twenty leaflets, each applicable to a particular industry, entitled "Instruments in Industry", which form a comprehensive guide to the various determinations that can most usefully be carried out using EEL photoelectric instruments. The fields of application include agriculture, ceramics, food, glass-making, medicine, photography and printing, plastics, sewage and water analysis, and textiles. The company has also produced a series of detailed method sheets for use with the EEL absorptiometer, the EEL flame photometer and the EEL colorimeter.

Textile Institute Scholarships

The Textile Institute is offering the following scholarships, for which applications should be made before April 30. The Textile Institute Cotton Industry War Memorial Trust Scholarship is intended to enable the holder to follow a whole-time course of study in textile technology at an advanced level (preferably, though not necessarily, a degree course) and/or obtain industrial training and experience of a special character at home or abroad for a period of three years. It has a maximum value of £300 for each of the first two years and £350 for the final year. The Peter Coats Scholarship is for two or three years to a value of not more than £100 per annum, for students at present studying in a public, grammar, or secondary technical school, or attending a part-time course at a technical college, who wish to take a course leading to a college diploma or other qualification in subjects connected with the cotton industry. The Rowland Spencer Scholarship, established in memory of the late Rowland Spencer of Helmshore, Haslingden, Lancashire, is open annually for training or research, to young persons of British nationality by birth who intend to enter and make their career in the textile industry and who are in their last year at a public, grammar, or secondary technical school or attending a technical college, or who have already qualified in textile technology, either as university graduates or as associate members of the Textile Institute. There is an annual grant of £100 during the period of this scholarship.

Canadian Society of Plant Physiologists

The Canadian Society of Plant Physiologists was founded at a meeting held in Saskatoon, Saskatchewan, on October 27, 1958. The new society grew out of a series of annual research conferences on plant physiology that had been held at various Canadian universities and research institutions during a period of eight years. The officers of the new Society are: *President*, Paul R. Gorham; *Vice-President*, E. R. Waygood; *Secretary-Treasurer*, D. Siminovitch; *Eastern Director*, R. O. Bibbey; *Western Director*, Stewart A. Brown. Correspondence can be addressed to the Secretary-Treasurer of the Society, Chemistry Division, Canada Department of Agriculture, Ottawa.

Biochemical Engineering

The various biological industries, including the large-scale production of citric acid, antibiotics, vitamins and other pharmaceuticals for both human and animal consumption have developed extremely rapidly during the past decade. These, together with the expanding food-processing industries, require men trained in the somewhat rare combination of fields of engineering, microbiology and biochemistry. Man has for long controlled the activities of micro-organisms and enzymes on an empirical basis, either using them for fermentation processes or inactivating them to enhance the storage life of food. A much clearer understanding of the mechanisms involved is emerging, which is bound to be applied progressively to industrial and farming problems, and which, ultimately, will do much to overcome world-wide problems of ill-health and malnutrition. Biochemical engineering will necessarily play a major part in these developments, and it is important that British universities and technical colleges provide sufficient well-trained men and women in this field, able not only to improve existing methods but also to develop new ones as the need arises. There has already been some move to provide suitable training at the University of Birmingham and elsewhere, and University College, London, is now offering a one-year postgraduate course in biochemical engineering, starting in October. It is aimed at co-ordinating fundamental chemical engineering teaching with the requirements of the biological industries and will be balanced to suit previous experience of the student.

Photoelasticity at University College, London

Fifty years ago the late Profs. E. G. Coker and L. N. G. Filon began their collaboration in the development of the photoelastic method of stress analysis. To-day the method is recognized all over the world as one of the most valuable aids to efficient engineering design. The jubilee is to be celebrated at University College London, where most of the work was carried out, by a commemoration lecture and an exhibition of work in photoelasticity at the College. Sir Arnold Hall, president of the Royal Aeronautical Society, will preside at the commemoration lecture, to be delivered by Col. H. T. Jessop on April 15 at 6 p.m. The exhibition will be open on April 15, from 7 to 9 p.m., and on April 16 and 17, from 10 a.m. to 1 p.m., 2 to 5 p.m., and 6 to 9 p.m. The lecture and the exhibition will be open to the public free of charge and without ticket.

Announcements

Mr. J. McNicholas, general manager of the Manchester Rivers Department, and Dr. C. H. Mortimer, director of the Marine Station, Millport, and secretary of the Scottish Marine Biological Association, have been appointed members of the Water Pollution Research Board from April 1, in succession to Prof. J. E. Harris and Mr. A. Holroyd, whose terms of office have expired.

A one-day symposium on "Separation Processes in Analytical Chemistry" organized by the Royal Institute of Chemistry will be held in the Inorganic Chemistry Lecture Theatre, South Parks Road, Oxford, on April 24, at 10.30 a.m. There will be no charge for admission, which is not restricted to members of the Institute. Further details can be obtained from E. S. Lane, Chemistry Division, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

The British Congress of Cosmetic Science, organized by the Society of Cosmetic Chemists of Great Britain, will be held in University College, Gower Street, London, W.C.1, during April 15–17. Sessions will be devoted to the analysis of raw materials; assessment of finished products; manufacturing or processing; and biological assessment. Further details can be obtained from the honorary organizer, Dr. R. H. Marriott, County Laboratories, Ltd., Honeypot Lane, Stanmore, Middlesex.

The second International Conference on Operational Research organized by the International Federation of Operational Research Societies (IFORS) will be held in Aix-en-Provence, France, during September 5–10, 1960. Suggestions for papers should be sent to the Secretary of IFORS, 11 Park Lane, London, W.1, before May 1, 1959, with a copy to the Secretary of the Operational Research Society of the country of origin. Manuscripts will be required by December 1, 1959, so that preprints can be made available before the Conference.

A symposium, intended for health physicists of atomic energy centres or installations, is being organized by the European Nuclear Energy Agency and the Danish Atomic Energy Commission, in co-operation with a number of scientists from Europe, from the United States and from Canada. It will be held at the Danish Atomic Energy Commission research centre at Risø, near Copenhagen, during May 25–28. The purpose of the symposium is to discuss scientific and technical aspects of health physics in atomic installations (radiation protection, control of radioactive contamination, emergency measures). Further information can be obtained from the European Nuclear Energy Agency, 38 Boulevard Suchet, Paris 16.

The twenty-fourth Cold Spring Harbor Symposium on Quantitative Biology will be held during June 3–10. The topic of the meetings will be "Genetics and 20th Century Mendelism"; and geneticists, anthropologists and palæontologists will participate. Individual sessions will deal with the theory of the gene and raw materials of evolution, natural selection and race formation, ecological systems and social organization, isolating mechanisms and speciation, the fossil record and rates of evolution, and trends of evolution. The Symposium is open to all who are interested, but because of limitations of space it is important to make advance reservations. Further information can be obtained from the Biological Laboratory, Cold Spring Harbor, New York.

The Tenth Congress of the International Astronautical Federation is to be held at Church House, Westminster, during August 31–September 5. Papers will not be restricted to a single theme, but will cover a wide range of astronautical topics, including: research applications of satellites and space-probes; existing and proposed projects for manned and unmanned space vehicles; conventional and unconventional methods of propulsion in space; problems in dynamics, control and navigation; re-entry problems; biological and medical aspects of manned spaceflight; legal problems. Papers for presentation should be submitted by June 1. Further details can be obtained from the Congress Secretariat, British Interplanetary Society, 12 Bessborough Gardens, London, S.W.1.

Nutritional Biochemicals Corp. of Cleveland, Ohio, has recently published its new catalogue listing more than 2,500 biochemicals for use in research and industry and now available through the Cleveland company. The catalogue can be obtained from the Nutritional Biochemicals Corp., 21010 Miles Avenue, Cleveland 28, Ohio.

THE NATURE CONSERVANCY

REPORT FOR 1957–58

THE ninth annual report of the Nature Conservancy for the year ended September 30, 1958*, follows the pattern of the previous report. There is a brief reference to the examination of the Conservancy's work conducted by the Select Committee on Estimates, and the Committee's recommendations in its seventh report for the session 1957–58 are being carefully studied. The declaration of fourteen new reserves during the year brought the total in Great Britain to seventy, with an area of 133,081 acres, and better progress was made in overtaking the arrears of estate management on existing reserves and in the preparation of management plans. The principles of land use and management emerging from ecological research and conservation have begun to take shape and to secure wider recognition, as in the recent reports of the Royal Commission on Common Land and of the Committee of Inquiry into Inland Waterways, and in the Government's introduction of a Bill for the conservation and control of red deer in Scotland on the lines of the recommendations submitted by the Nature Conservancy and the main interested national organizations in Scotland.

Research grants to universities and outside bodies were again severely restricted by lack of funds, but the Conservancy welcomes the review of grant policy described in the last annual report of the Advisory Council on Scientific Policy and is examining its own functions in this respect. Three new grants became effective during the year and eight were extended or renewed. The creation of the new Council for Nature is warmly welcomed, and the Conservancy is already planning liaison with the Council in the fields of education and public relations.

The recommendations of the Royal Commission on Common Land regarding the avoidance of permanent enclosure and the preservation of common land as a national reserve to be available for multiple uses are closely in line with the Nature Conservancy's approach, but the Conservancy considers that the absence of detailed provisions for enabling commons in poorer areas to be brought under satisfactory management in the national interest, or in that of adjoining wealthier regions wishing to use common land for amenity or other purposes, is a serious weakness, and the report appears to pass somewhat lightly over the very real problems of relating the use of each area to its soil capability and to the use of adjoining areas of common land.

The Nature Conservancy considers that the findings and recommendations of the committee of inquiry into inland waterways deal adequately with matters raised in the Conservancy's evidence to the committee. No evidence was submitted by the Conservancy on the future of the Norfolk Broads, and while the committee was not impressed by the proposal to make the Broads a national park, it thought that an expenditure of £30,000–£60,000 a year in place of the present £19,000 would be sufficient if the Great Yarmouth Port and Haven Commissioners were reconstituted (possibly including nominees of the National Parks Commission and the Nature Conservancy). The Conservancy agrees that these proposals would not run contrary to the interests of the naturalist and scientist, as some broads are unlikely to be restored to navigation and can be retained primarily as nature reserves. Moreover, the Conservancy urges that it is imperative to stay the deterioration of the broads and that this would not prejudice further action in the light of long-term research. The Conservancy considers there is no reason why agreement should not be reached on these lines.

Apart from recording progress in national nature reserves, the section of the report dealing with conservation is of particular interest for the details given of the management plans for three reserves: Woodwalton Fen (Huntingdonshire), Roudsea Wood (Lancashire) and Newborough Warren–Ynys Llanddwyn (Anglesey). For the first the objectives are: to conserve the characteristic plant and animal communities, including rare species of special interest which exist on the Fen; to encourage and carry out research and survey work on the fauna and flora of the Fen, and any other subject which may increase our knowledge of fen natural history and the factors which influence it; and to permit access to the reserve by interested members of the public, provided a permit is held, and to allow reasonable collecting, as well as to maintain good relations with neighbours with respect to boundary dykes, water levels in external systems and control of pests. For Roudsea Wood, the plan aims to establish a sample of native woodland characteristics of north-west England; to encourage the fauna and flora associated with this; and to provide facilities for study and research. The principal objectives at Newborough Warren are to carry out detailed surveys and to compile records of the entire range of scientific interests; to conserve examples of distinctive dune and slack flora and fauna; to increase the diversity of wild life within the reserve by extending some habitats and creating new ones; to enrich the ornithological interest, by influencing the balance of populations to preserve adequate numbers of species of birds and mammals most characteristic of the habitat; to control public access by a permit system, but to allow as much freedom as is compatible with conservation and research; and to develop the educational potentialities of the reserve.

Both the sections of the report dealing with conservation and that dealing with scientific research describe in some detail the rapid progress made in providing man-power, accommodation and other resources to make a firm base for research and con-

R316

servation on the Isle of Rhum. It has been shown conclusively that it is impracticable to produce commercial timber on Rhum, and the immediate and medium term productive potential of Rhum is being assessed, particularly as regards livestock and red deer. The Macaulay Institute of Soil Research is making a comprehensive soil survey, and a preliminary report has already resulted on the soils and geology of Rhum. A programme of vegetation recording has presented a picture of widespread erosion of the soil and deterioration in the quality of the cover.

In this report the section describing the scientific advisory services of the Conservancy is specially interesting. At Milford Haven the developers submitted new alternative proposals involving the exploitation of old gravel workings high up the shore, which will not be inimical to the scientific interest of the area, after it had been pointed out that the original plan to extract sand and gravel from Dale Bay and the adjacent Gann Flats would destroy the existing delicate balance of environment and living organisms within the Crabhall Saltings and the Dale Bay shore. The outcome of this case thus illustrates how early and full discussion between developers, planning authorities and the Conservancy can avoid developments which would be inimical to wild life. A detailed biological survey of the estuary is being undertaken by Prof. E. W. Knight-Jones with a grant from the Development Commission. Increased urgency was expressed over the conservation and use of water and the need of ancillary research, particularly in opposing the Tees Valley Water Board's proposal to build a reservoir in Upper Teesdale, and special attention has been directed to accurate methods of measuring rainfall, loss of water from evaporation and run-off.

Further representations were made in connexion with the use of chemical sprays to control vegetation on roadside verges, but it has not yet been possible to set up the panel on risks to wild life. The Conservancy has not so far received any substantial evidence that toxic chemicals used in agriculture are causing any important or widespread reduction in bird or mammal populations. The red deer survey undertaken by Dr. Fraser Darling has now provided detailed information on about one-third of the ground in Scotland on which red deer are established, and sufficient material to prepare, negotiate and adopt a soundly based national scheme for red deer conservation and control in Scotland acceptable to all the main interests concerned. The Conservancy has been enabled to develop a red deer research programme and provided with the experience and resources to undertake further development of investigation and advising services in this field. The present red deer population of Scotland is estimated at about 120,000, and it is hoped that the Deer (Scotland) Bill, which received its second reading in the House of Commons on February 3, will put a stop to the cruelty from poaching by gangs, which is the most urgent aspect of the problem. The red grouse investigation continued, as well as research on seals on the Farne Islands. The Development Commission was considering the possibility of a grant to continue and expand the research on grey seals by appointing a zoologist to investigate the fishery and marine biological aspects.

Among the research programmes which have already yielded definite results is the vegetation survey of the Scottish Highlands which had led to improved understanding of the reasons for the striking patterns of contrasting heather and grass moorlands and bracken and scrub-covered slopes which are so conspicuous in the Highlands. The Conservancy proposes to apply this knowledge within its own mountain reserves and to attempt to unravel some of the problems the Survey has indicated with the view of demonstrating a sound system of hill management. The geological survey of the Moor House Nature Reserve has been in progress for four years and work continued on the experimental introduction of Arctic–Alpine and montane species of plants into selected areas fenced off to exclude sheep. A study of the productivity of alluvial grasslands was initiated as well as longer-term experiments to estimate the annual production of plant material by peat under different regimes of extraction cropping. Other experiments at Moor House relate to the reclamation of eroded peat areas, the establishment of high-level woodland, the relation between seasonal growth in height of Scots pine, rowan and birch, and air temperature and soil temperature at rooting depth. In a further study of the craneflies (Tipulidae) particular attention is being paid to the short-palped craneflies which are restricted to peat moor.

In Snowdonia investigations on the soils, vegetation and land use continued, and the recording of chalkland grassland transects in south-east England has afforded evidence of continued increase in the proportion of the more palatable grasses and the legumes in places where the numbers of rabbits had been much reduced.

Seven important papers have now been published on the development of woodland conditions under different trees and major sections of this research are now complete. In the present report, work on the influence of site factors on sessile oak (*Quercus petraea*), Scots pine (*Pinus sylvestris*) and silver birch (*Betula verrucosa*) is described, as well as continued studies on the oak and ashwoods of northern England, and on the defoliation of oaks by the oak-leaf roller moth (*Tortrix viridana*). Besides detailed studies of the ecology of earthworms at the Moor House Nature Reserve, the study of earthworms in woodland soils is an expanding part of the work of the Merlewood Research Station. Studies of the ant populations of east Dorset heathland and on dragonflies continued, as well as the study of the population cycle and food of the short-tailed vole (*Microtus agrestis*), and the investigation on the pine martin on Benin Eighe. In coastal research the survey of brackish marsh communities of *Spartina townsendii* in Poole Harbour was extended from Arne Bay to the north shore of the harbour at Keyworth and Lytchett Bay. Studies are being made of the rate of accretion of mud on *Spartina* marsh in Bridgwater Bay and of the control of *Spartina* by herbicides. A further study has confirmed that Brent geese make use of a much wider range of salt-marsh foods at Scolt Head Island than has been generally supposed. Experimental work into the movement of beach material at Bridgwater Bay has yielded interesting results on the development of shingle complexes and on the interaction of shingle and grass. The large-scale mapping of the physiographical forms of the coast eastwards of Hinkley Point has been completed. At Braunton Burrows extensive planting of marram grass (*Ammophila arenaria*) has effectively stabilized much of the dune area over which military movements had destroyed the protective cover of vegetation.

THE NATIONAL PARKS COMMISSION

REPORT FOR 1957–58

THE ninth annual report* of the National Parks Commission covers the year ended September 30, 1958, and records the establishment of three further areas of outstanding natural beauty, the Minister having confirmed the Commission's orders designating the Northumberland coast, the Surrey hills and Cannock Chase. Decisions are awaited on the Dorset coast and hinterland and the Shropshire hills, and the Commission expects during the next few months to be submitting for confirmation orders for the Cornwall areas, sections of the north and south Devon coasts, the Malvern Hills and the Sussex Downs. As regards the 'Long Distance Routes', the Commission has completed its report on the South Devon Path and its work on the North Devon Path is well advanced. Solutions are being sought for a new line in the Pennine Way, the Blakehope Fell area of Northumberland, and this will leave Edale Bridge as the only major problem of the route outstanding. The Commission again comments on the good work being done by voluntary assistance in clearing disfigurements from disused gun-sites and other sites of wartime activities in the Pembrokeshire Coast National Park, the Lake District, the Peak District and elsewhere, but rightly points out that it is a national disgrace that so many disfiguring marks should still remain. It welcomes the assurance given in the House of Commons on July 2 by the Parliamentary Secretary to the Ministry of Housing and Local Government that purchasers of an airfield are now required to leave it reasonably tidy.

As regards the National Parks themselves, the Commission's report stresses the creative work being undertaken in the Peak District, where the Board's current programme includes many plans for the removal and concealment of scars and blemishes on the landscape; public access is being extended, as well as information work and the development of the voluntary warden service. In the Lake District, caravan sites have received much attention and anti-litter work has increased, while in Snowdonia an economic survey of the Park is proposed with particular reference to amenity. Substantial agreement was also reached with the Forestry Commission, through the Forestry Consultative Panel, on the definition of zones within the Park where the Forestry Commission would undertake not to carry out planting, and of further zones where planting would only occur after consultation with the Committee. The Park Planning Committee for Dartmoor has now reached agreement with the South Western Electricity Board on detailed procedure for early informal consultation on proposals for overhead electricity supply lines within the Park, and its efforts to remove or mitigate disfigurements and advertising continued to meet with success. Anti-litter work further developed in the North York Moors, and in the Yorkshire Dales the West Riding Park Planning Committee reports further negotiations for public access to Barden Moor and Barden Fell.

The report of the Commission refers to new action to secure publicity for "The Country Code" and for national parks in general as well as to the campaign to abate the litter nuisance. Nearly four hundred development proposals were referred to it during the year, and the Commission does not conceal its disquiet at the granting of Ministerial consent for three major industrial undertakings in National Parks. These decisions must result in grievous damage to the landscape of the Snowdonia and the Pembrokeshire Coast Parks, and the particular and general issues involved are discussed in some detail in the report, while examples of other development issues handled during the year are given in appendixes. These three development proposals and a series of Acts with a direct bearing on the work of the Commission are regarded as the outstanding features of the year under review, but their implications are considered elsewhere.

MAGNETIC FIELD OF THE EARTH

IN recent years the maintenance of the Earth's magnetic field has generally been ascribed to dynamo interaction between the field and convective motions in the Earth's core. Such an explanation receives support from the relatively rapid fluctuations in the field and its apparent reversals during geological times. However, theoretical investigations of the suggestion have met considerable difficulties. The field is supposed to be expanded in a series of harmonics, and in order to get soluble equations it is necessary arbitrarily to chop off the series at an appropriate point. Questions of convergence arise, and though the work of Bullard and Gellman, using all the resources of an electronic computer, made the convergence appear plausible, it could do no more.

A recent paper by A. Herzenberg* has discussed a dynamo model for which the question of convergence can be decisively answered. He represents the Earth by a large solid conducting sphere; two eddies in its interior are represented by smaller solid conducting spheres with their centres some distance apart, and which are constrained to rotate uniformly around diameters. The smaller spheres are in electrical contact with the material of the larger one, in which they are imbedded.

The system operates as a self-exciting dynamo if the angular velocities of the inner spheres are sufficiently great, and their axes of rotation are suitably oriented. The mechanism of dynamo maintenance is roughly as follows. The rotation of the first sphere twists the lines of magnetic force which penetrate the sphere, and generates a magnetic field large compared with the exciting field, the lines of force of the induced field being circles around the axis of rotation. This induced field is propagated through the surrounding material to the vicinity of the second sphere, where it provides a seed field which is similarly twisted by the rotation of that sphere and provides a much larger field with lines of force around the axis of rotation. This induced field in its turn is propagated back to the first sphere, where it provides the primary field which is twisted by the rotation of the latter. With roughly half the possible directions of the axes of rotation, the dynamo interaction amplifies the existing field. Herzenberg finds it necessary to discuss the reflexion of magnetic fields at the boundary of the large sphere, but it is difficult to believe that this can have any decisive importance to maintenance of the dynamo.

---

* *Philosophical Transactions of the Royal Society of London*, A, 250 (21 August, 1958): Geomagnetic Dynamos. By A. Herzenberg. Pp. 543–585. (London: Royal Society, 1958.) 13s.

Herzenberg's mechanism possesses definite advantages from the mathematical point of view. If the distance between the centres of the smaller spheres is sufficiently great, the higher-order harmonics of the field which is induced by the rotation of one sphere are strongly attenuated before they reach the other sphere. This ensures the convergence of the expansions used by Herzenberg; a large part of his paper is, in fact, concerned with the convergence. The mechanism also has the advantage that the method of feedback is clearly evident; in Bullard and Gellman's work the same mass of fluid partook of two different sorts of motion at the same time, and it was virtually impossible to separate the effects of the two motions.

Like other earlier workers, Herzenberg made no attempt to consider the reaction of the induction process on the motion which causes it, and indeed his mechanism does not lend itself to considering such a reaction. The reaction must clearly be important, and be responsible for the tendency for the Earth's magnetic axis to approximate to its axis of rotation. Thus the importance of Herzenberg's work is primarily not physical, but mathematical. It decisively clears up any lurking doubts about the dynamo theory due to defects of convergence in earlier discussions. In considering the physical picture it is now no longer necessary to worry lest deeper research may show that failures of convergence invalidate the whole dynamo hypothesis.

T. G. COWLING

RAILWAY ECONOMICS

ALTHOUGH it appeared after the House of Commons debate on December 11, when the Transport (Borrowing Powers) Bill received its second reading, the broadsheet, "Paying for the Railways" (No. 429. December 19, 1958), issued by Political and Economic Planning, throws much further light on the problem of the future of railways, reviewing briefly the origin of the financial difficulties of British Railways since the War, the policies recently proposed, including the problem of wages, and finally setting forth four possible alternative solutions. In moving the second reading of the Bill, Clause 1 of which extends the borrowing powers of the British Transport Commission by a further £600 million, the Minister of Transport and Civil Aviation, Mr. H. Watkinson, said that the crux of the problem was how the railway system of the Victorian age could streamline itself to fit the age of the motor-car and nuclear power. For the first forty-four weeks of 1958 merchandise traffic was 14 per cent below 1957 and 10 per cent on 1956. Nevertheless, the Commission was pressing on with modernization of heavy traffic, but it was inevitably slow and took long to come to fruition. By the end of 1958, fitted freight trains would represent 35 per cent of the whole and wagons fitted with continuous brakes number 270,000; 44,000 containers suitable for door-to-door carriage would be in use, 150 older marshalling yards would be closed and 27 new yards constructed. Each working day 4 million passengers and 1 million tons of freight were moved.

Mr. Watkinson said a severe fall in heavy freight traffic in the last two months of the year was the main cause of the deficit for the year, which is expected to be about £85 million. Transport of coal was at present down by about 500,000 tons a week; production of crude steel in 1958 was probably about 10 per cent lower than in 1957, and the Commission's report indicates a fall in receipts from coal and mineral transport of more than £600,000 a week on 1957, but assumes that this is a temporary decline, calling for temporary measures only.

Mr. Watkinson said that at his request the Commission had already initiated a full, detailed and urgent review of the whole modernization plan, taking account of both present and probable changes in traffic in the light of the probable level of activity in the coal industry, in view of competition from oil and future developments in nuclear energy. He hoped to lay the findings of this review before Parliament by the early spring. Meanwhile, with the Government's full support, the Commission was proceeding with more modernization on a narrower front. It proposed to concentrate resources for main-line electrification on the London Midland and Scottish line to Manchester and Liverpool and to accelerate its completion by several years. The introduction of diesel locomotives to eliminate the use of steam would be accelerated as quickly as possible on an area basis, particularly on routes north of Newcastle upon Tyne: by 1961 nearly 1,100 main line diesel locomotives would be in use. Multi-unit diesel trains would be doubled, from 2,300 to 4,600, by the end of 1961. As a result of these and other measures the Commission expected to achieve additional savings of at least £30 million in a full year. Although there had been a reduction in the labour force of 20,000 during the past year, this had been effected with proper agreements between the Commission and the trade unions. In replying on the debate, Mr. C. R. H. Nugent, Joint Parliamentary Secretary to the Ministry, referred to the encouraging position of passenger services, revenue for which in November 1958 showed an increase of £0·3 million on 1957. The Minister himself also referred to the success of some of the luxury trains and to the Commission's intention to pursue a more flexible policy in fares.

Dealing with the modernization programme, first published in 1955, the Planning broadsheet agrees that the most important feature, the gradual substitution of electric or diesel traction for steam locomotives, as well as the plans for extending automatic train control and colour light signalling, fitting all goods trains with vacuum brakes, the improvement of express train services and provision of door-to-door containers, should both provide economies and improve the quality of passenger and freight services. If the expectations of the Commission are justified, the initial cost of the modernization programme should be covered by improved revenues, and there is no justification for slowing down the programme to remove an immediate financial predicament.

The broadsheet is more critical of the policy of cutting uneconomic services, and while some adaptation of railway services is obviously necessary in the light of those provided by road hauliers and road passenger undertakings, Political and Economic Planning does not consider it is always in the interest of the railways to cut their services to solve an immediate financial problem. In reducing the frequency of passenger services the railways are following a dangerous policy of reducing costs by lowering the standard of their service, and experiment with the variety of alternative means of curtailing losses is advocated. Rejecting as economically unsound a flat subsidy without any re-organization of the national transport system, it points out that the solution of allowing the railways to operate purely as a commercial undertaking would involve a break with their long tradition of public service obligations. Although this would probably not cause serious hardship because so many alternative forms of private transport are now available, it is politically controversial although economically sound.

That also applies to the solution by joint control of the transport system as a whole by the same undertaking, as was envisaged when the British Transport Commission was created. The merits of the transport structure which emerged from nationalizing road haulage and long-distance '*C*' licence road transport, however, would depend on the way in which co-ordination plans were formulated and implemented. The solution suggested by J. R. Sargent as a solution to the problem of unremunerative public transport services depends on a compromise between a commercial undertaking and a public service with the merits of each clearly defined, and has the merit of being politically neutral on the question how far the railways should function as a public service, since the decision how many, and which, services should be subsidized is referred to another authority. It could be applied without imposing any drastic changes on the ownership of the rest of the transport sector. The choice between any of these solutions, however, involves first a Government decision whether it wishes unremunerative services to be continued. If so, the Government must decide how these services should be financed, and in choosing the method to be used, the effects on the efficiency of transport as a whole and on the current distribution of work between road and rail require careful examination. Finally, Political and Economic Planning insists that decisions on these matters are urgent.

POSSIBLE ENZYMIC MECHANISM FOR THE DEVELOPMENT OF RESISTANCE AGAINST FLUOROURACIL IN ASCITES TUMOURS

By Dr. PETER REICHARD and OLA SKÖLD

Department of Chemistry I, Karolinska Institutet, Stockholm, Sweden

AND

Prof. GEORGE KLEIN

Department of Tumour Biology, Karolinska Institutet, Stockholm, Sweden

THE uracil analogue 5-fluorouracil was introduced by Heidelberger *et al.*[1] as an antimetabolite inhibiting tumour growth. In extensive metabolic studies[2-5] it was demonstrated that the pyrimidine was incorporated into ribonucleic acid of both normal tissues and tumours and, furthermore, that the compound inhibited the incorporation of labelled formate and uracil into deoxyribonucleic acid-thymine of Ehrlich ascites cells both *in vivo* and *in vitro*. The latter finding together with similar results by Eidinoff *et al.*[6] suggested a block in the methylation of deoxyuridine-5′-phosphate. Cohen *et al.*[7] recently demonstrated such an inhibition of thymidine-5′-phosphate synthetase from *E.coli* by 5-fluorodeoxyuridine-5′-phosphate.

These studies indicate two points at which the fluoropyrimidine might interfere with nucleic acid metabolism[1,5]: (1) inhibition of synthesis of deoxyribonucleic acid through the inability of the cells to synthesize thymine; (2) formation of a 'fraudulent' ribonucleic acid containing fluorouracil in place of uracil. Both mechanisms seem to require a transformation of the fluoropyrimidine to the nucleotide stage, and such transformations to fluorouridine phosphates and fluorodeoxyuridine-5′-phosphate, respectively, were also observed to occur in the ascitic cells[3,5]. In line with this idea is also the demonstration that in several tumours 5-fluorouridine and/or 5-fluorodeoxyuridine had a considerably higher tumour-inhibiting activity than the free pyrimidine[8].

Fluorouracil also strongly inhibits uridine phosphorylase[9] and thus inhibits synthesis of ribonucleic acid from uracil. This type of inhibition might also contribute to the carcinostatic activity of the compound.

One of our laboratories has for some time been interested in the utilization of uracil for synthesis of nucleic acid as an alternative mechanism for pyrimidine synthesis[10]. It was found that the Ehrlich ascites tumour possessed relatively high activities of the enzymes uridine phosphorylase and uridine kinase which, by their combined action, transform uracil to uridine-5′-phosphate[11]:

$$\text{uracil} + \text{ribose-1-phosphate} \rightleftharpoons \text{uridine} + \text{phosphate} \qquad (1)$$

$$\text{uridine} + \text{adenosine triphosphate} \rightarrow \text{uridine-5'-phosphate} + \text{adenosine diphosphate} \qquad (2)$$

It was also found that these two enzymes occur at much higher concentrations in the tumour than in mammalian liver[12] and in most other normal tissues[13].

In the Ehrlich ascites tumour, uracil is also transformed to deoxyuridine-5′-phosphate through the combined action of deoxyuridine phosphorylase and deoxyuridine kinase:

$$\text{uracil} + \text{deoxyuridine-1-phosphate} \rightleftharpoons \text{deoxyuridine} + \text{phosphate} \qquad (3)$$

$$\text{deoxyuridine} + \text{adenosine triphosphate} \rightarrow \text{deoxyuridine-5'-phosphate} + \text{adenosine diphosphate} \qquad (4)$$

The enzymes catalysing reactions 1 and 3, respectively, have been partially separated by ammonium sulphate fractionation[14], while there is only indirect evidence that reactions 2 and 4 are catalysed by two different enzymes.

Fluorouracil can be substituted for uracil in reactions 1 and 2 and thus give rise to fluorouridine-5′-phosphate[9]. A similar substitution of uracil in reactions 3 and 4 has not yet been demonstrated, but seems very likely.

It is well known that tumour cell populations can become resistant against different types of antimetabolities when exposed to prolonged treatment. It has been suggested that such changes have a mutation-selection basis, in analogy with similar events in microbial populations[15]. Very little is known about the biochemical nature of such hypothetic mutations. The purpose of our investigation was to determine whether any change occurs in the activities of some of the enzymes described above concurrently with the development of resistance against fluorouracil. We were particularly encouraged by the report of Heidelberger *et al.*[8], who mentioned the occurrence of a line of an Ehrlich ascites tumour, resistant to fluorouracil but susceptible to fluorouridine, and also by experiments with bacterial mutants resistant against azauracil[16] and 6-mercaptopurine[17].

Fluorouracil-resistant lines were developed from the Ehrlich ascites tumour and the ascitic form of lymphoma *L* 1210 by serial transfer under prolonged treatment. Heterozygous mice were inoculated with 10^6 cells of the Ehrlich tumour while the same number of *L* 1210 cells were injected into the peritoneal cavity of *DBA*/2 mice. The animals were treated by intraperitoneal injections of 20 mgm./kgm. fluorouracil every second day, starting the day after inoculation. As a rule, 10 mice were treated while 5 were left as untreated controls. As soon as any of the treated animals developed ascites, they were punctured and about 1 ml. of fluid was collected. After appropriate cell counts have been made, 10^5 cells were inoculated to a new recipient group, consisting of 15 mice. In this new group, 10 mice were again treated while 5 served as controls. If ascites became available in the treated group, the procedure was repeated in the same way.

Three independent lines of the Ehrlich ascites tumour were treated. Considerable inhibition was obtained in the first generation, in agreement with the findings of Heidelberger *et al.*[1]. Two lines did not show any tendency to increased resistance and were lost after 3 and 5 passages, respectively. A third line showed a marked increase in resistance during prolonged treatment (Fig. 1). The increase in resistance was particularly pronounced between the third and fourth transfer, and by the fifth passage resistance was nearly complete, although not absolute, as indicated by the survival curves of Fig. 1. No additional increase in resistance has been observed during six consecutive passages under treatment.

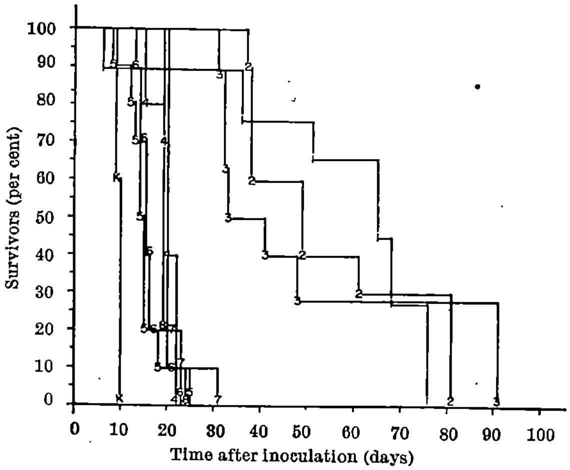

Fig. 1. Survival curves of fluorouracil-treated mice inoculated with untreated Ehrlich ascites tumour cells (group *K*) and with cells carried under prolonged treatment for 1–8 passages (groups 1–8). *K*, control; 1–8, first to eighth treated generations

L 1210 was much less sensitive than Ehrlich but showed, nevertheless, a slight but definite inhibition during fluorouracil administration. This inhibition decreased in the course of prolonged treatment and was entirely abolished after six passages (Fig. 2).

The enzymes of reactions 1–4 were assayed in extracts of acetone powder and in tumour homogenates[12,13]. Table 1 shows that, within the limits of our methods, both uridine and deoxyuridine phosphorylases were absent from the resistant Ehrlich ascites cells. Some decrease in uridine kinase activity also occurred whereas deoxyuridine kinase activity showed little changes.

In another experiment intact Ehrlich ascites cells were incubated with uracil labelled with carbon-14 at

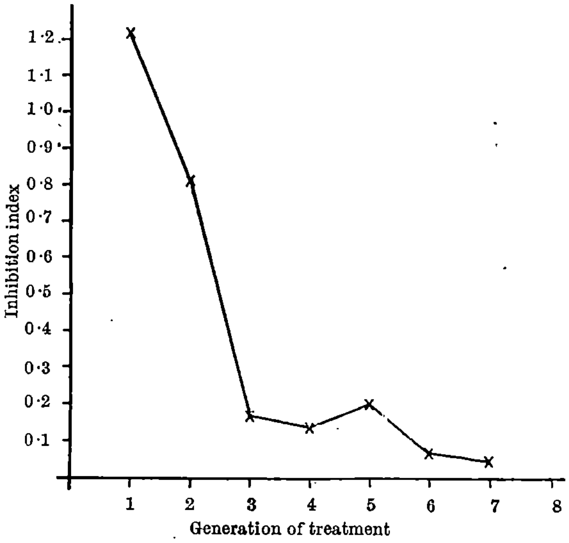

Fig. 2. Inhibition index (mean survival time of treated mice–mean survival time of controls/mean survival time of controls) of *DBA*/2 mice inoculated with lymphoma *L* 1210, under consecutive passages in the presence of fluorouracil treatment

Table 1. DETERMINATION OF ENZYME ACTIVITIES IN A NORMAL AND FLUOROURACIL-RESISTANT STRAIN OF EHRLICH ASCITES TUMOUR

	Acetone powder extracts		Homogenates	
	Normal	Resistant	Normal	Resistant
Uridine phosphorylase	74	< 0·5	11	< 0·5
Uridine kinase	80	25	5·3	2·7
Deoxyuridine phosphorylase	30	< 0·5	3·6	< 0·5
Deoxyuridine kinase	1·5	2·7	—	—

The values are given as mμmoles of product per mgm. of acetone powder or per mgm. wet weight (10 per cent homogenates) formed during 15 min. incubation at 37°.

Table 2. ANALYSIS OF ACID-SOLUBLE FRACTION FROM INTACT ASCITES CELLS AFTER INCUBATION WITH URACIL LABELLED WITH CARBON-14

	Normal cells	Resistant cells
Uracil	540	370
Uridine	1·6	—
Uridine-5′-phosphates	151	< 2
Deoxyuridine-5′-phosphate	0·8	—
Thymidine-5′-phosphates	1·5	—

The values represent mμmoles of the different compounds in one ml. of ascitic cells.

37° for 30 min. in Tyrode solution. Analysis of the acid-soluble fraction (Table 2) showed that the normal and resistant cells were permeable to uracil to about the same extent. In the normal cells uracil also gave rise to uridine-5′-phosphate. Besides small amounts of uridine, deoxyuridine-5′-phosphate and thymidine 5′-phosphates were also formed by the normal cells. No significant amounts of any of these compounds were found in the resistant tumour.

Enzyme determinations were also carried out in a normal and fluorouracil-resistant line of lymphoma *L* 1210 (Table 3). The normal tumour is much less susceptible to inhibition by fluorouracil than the Ehrlich ascites tumour, and it is interesting that in the normal lymphoma both phosphorylases show a relatively low activity. The changes in enzyme activities from the normal to the resistant lymphoma are less spectacular than in the Ehrlich ascites tumour, but it is nevertheless evident that a considerable decrease in uridine phosphorylase and kinase activities had taken place.

Table 3. DETERMINATION OF ENZYME ACTIVITIES IN ACETONE POWDER EXTRACTS OF A NORMAL AND A FLUOROURACIL-RESISTANT STRAIN OF LYMPHOMA 1210

	Normal	Resistant
Uridine phosphorylase	10	5
Uridine kinase	67	16
Deoxyuridine phosphorylase	4	4
Deoxyuridine kinase	3	3

For explanation of values see Table 1.

In summary, our experiments with the Ehrlich ascites tumour indicate that during the development of resistance the cells lost the capacity to transform uracil (and therefore also fluorouracil) to the riboside and the deoxyriboside. The fact that both enzymes are missing from the tumour might mean that the cells must lose both the ability to incorporate fluorouracil into ribonucleic acid (which proceeds via the riboside) and the ability to form fluorodeoxyuridine-5′-phosphate (which proceeds via the deoxyriboside) before a complete resistance against the drug has developed. Alternatively the loss of both enzymes might take place simultaneously through a single genetic event, even though the two enzyme activities are represented by two different proteins, which can be separated from each other by ammonium sulphate fractionation.

It is hoped that a choice between these two alternatives will be possible through an analysis of the enzyme pattern of partially resistant lines. Further experimentation is also required before one can decide whether resistance against fluorouracil in the Ehrlich ascites tumour generally is due to a lack of one or several of the enzymes necessary for the transformation of the pyrimidine to nucleotides, or whether such a mechanism only represents one of several possibilities.

This work has been supported by research grants from the Swedish Cancer Society, the Lady Tata Memorial Trust and the Damon Memorial Fund for Cancer Research. We wish to thank the Hoffmann-La Roche Co. for a generous gift of 5-fluorouracil.

ELECTRON-MICROSCOPIC STUDY OF FINBACK WHALE MYOGLOBIN CRYSTALS

By D. E. BRADLEY

Research Laboratory, Associated Electrical Industries, Ltd., Aldermaston Court, Berks

THE visualization of the molecular arrangement in crystals of virus proteins of high molecular weight has been successfully achieved by Wyckoff and Labaw[1]. More recently, Dawson and Watson[2] studied the crystal structure of the protein ribonuclease, which has a lower molecular weight, using carbon replicas, and in addition, direct examination. These two methods of examination have also been used in the study of myoglobin described here.

The protein myoglobin has been studied in detail by X-ray analysis, and, with the information obtained, it has been possible to build up a three-dimensional model of the molecule[3]. The dimensions of the molecule are 43 A. × 35 A. × 23 A., well within the limit of resolution of the electron microscope and existing specimen preparation techniques. It would therefore seem possible that these molecules, or at least structures relating to the unit cell, could be seen in crystalline myoglobin. The dimensions of any such structures observed could then be related to the X-ray results.

The two possible approaches to the electron microscopy of protein crystals have already been mentioned. The specimen can either be examined in transmission, or by means of replicas, which give a picture of the surface topography. In the case of transmission, very thin crystals must be used to permit penetration by the electron beam. With replicas, a technique permitting the attainment of reasonably high resolution is required. Electron micrographs of the myoglobin lattice have been obtained by both methods, but the most useful information has so far come from surface replicas.

Myoglobin can be obtained from many different animals, and crystallizes in different forms[4]. In this examination, the material was obtained from the finback whale and recrystallized from sodium and potassium phosphates, the resulting crystals being known as type *F* myoglobin. The X-ray analysis has been described by Kendrew and Pauling[5]; the crystal morphology given by them is as follows.

The crystal habit is orthorhombic, the crystals being in the form of six-sided plates with the flat face the {001}. There are two inclined side faces which are {101}, and the remaining four vertical side faces are {210}, as shown in Fig. 1. It can be seen that this form of crystal is particularly suitable for electron microscopy since the {001} face will be predominant and easily recognizable, and the {210} will be distinguishable from the {101}.

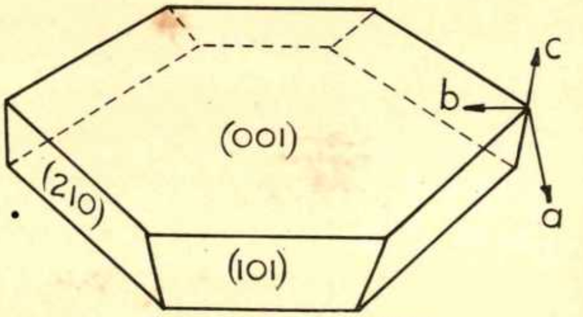

Fig. 1. Type *F* myoglobin crystal

The lattices of many proteins shrink when the crystals are removed from the suspending liquid and dried. This is the case with myoglobin; the following cell constants are given by Kendrew and Pauling[5]. In wet conditions $a = 97 \cdot 4$ A., $b = 39 \cdot 8$ A., $c = 42 \cdot 5$ A. In dry conditions $a = 88$–94 A., $b = 36$–37 A., $c = 35$–38 A. The reason why a range of values is given is that the degree of shrinkage in dry crystals is not constant.

Before proceeding with the preparation of replicas, it was necessary to separate the crystals from the ammonium phosphate solution in which they were suspended and to mount them on a suitable substrate without resuspension in any other liquid medium. This precaution was taken in order to minimize disturbance of the molecular organization. The operation was carried out by placing a drop of the suspension on a thin, freshly cleaved mica sheet which had been pierced with a needle. The underside of this sheet was pressed against a filter paper, and the suspending liquid drained through the hole, leaving the crystals behind.

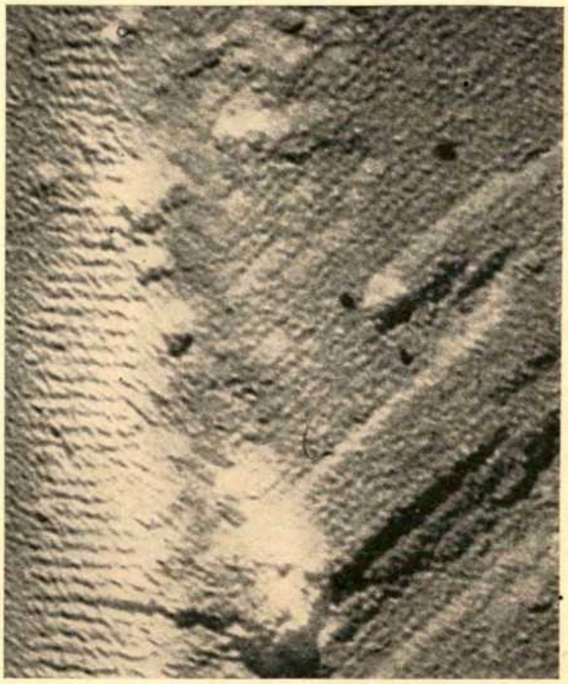

Fig. 2. {001} and {210} faces of a type *F* myoglobin crystal. Platinum/iridium/carbon replica (angle 2 : 1) The larger spacing is on the {210} face. (× 200,000)

Replicas were made by placing the mica strip in a vacuum plant and depositing a thin film containing platinum, iridium, and carbon using an evaporating technique described elsewhere[6,7]. The combined film and crystals were floated on to water, where the crystals dissolved, leaving a replica ready for mounting on support grids. The simultaneous evaporation of the three elements provided an amorphous deposit containing very sharp shadows (the angle being 2 : 1). Though the same structure could be observed using conventional platinum metal shadowing, the result was somewhat sharper using the technique described.

Electron micrographs were obtained of the three crystal faces mentioned, and of these, the {001} and {210} showed a periodic structure (Fig. 2). This consisted of dark lines parallel to the *b* and *c* axes respectively. A close examination of some micrographs indicated that the dark lines were grooves rather than steps. The spacings were measured over a number of micrographs of different crystals and gave an average value of 88·5 A. for the {001} face and 114·5 A. for the {210}. Assuming that the grooves correspond to the unit cell structure, the spacings observed on the {001} face should be equal to *a* and the spacing on the {210} to its projection, which is $\sqrt{a^2 + 4b^2}$. The value of *b* obtained by equating this expression with the observed 114·5 A. is 36·5 A. The experimental values $a = 88 \cdot 5$ A. and $b = 36 \cdot 5$ A. are consistent with the unit cell dimensions of the dry crystals.

While no periodic structures from which the value of *c* could be calculated have so far been observed, an approximate value can be estimated from the layer growth structures which have been observed on the

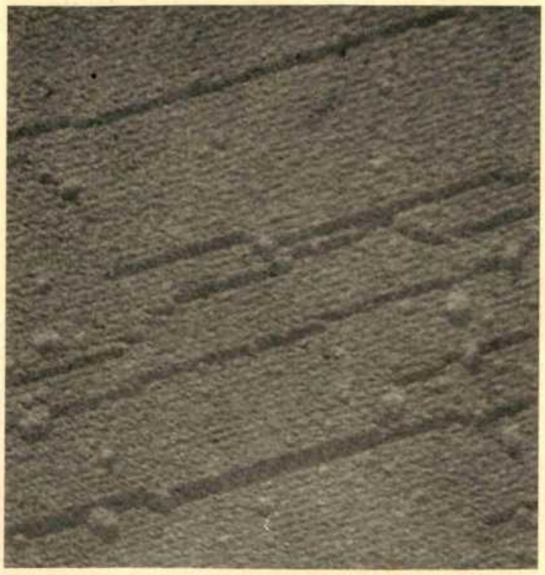

Fig. 3. {001} face of a type *F* myoglobin crystal showing layer growth. Platinum metal shadowed (angle 2 : 1) carbon replica. (× 125,000)

{001} faces (Fig. 3). The thicknesses of the layers can be calculated from lengths of shadows and should correspond to an integral number of *c* spacings. A large experimental error arises because the crystals may be tilted on the mica sheet, so giving a range of different shadowing angles. The value obtained in this way is (43 ± 15) A. Taking into account the experimental error, this result is consistent with the *c* dimension for dry crystals.

This method for measuring the c dimension is more accurate if the step consists of a large number of units (at least 10) so that the step height is large (at least 200 A.), as is the case with steps on cleaved sucrose[7].

It has already been mentioned that the myoglobin lattice can be seen in direct electron micrographs of thin regions of the crystal. This fact, together with the results of Dawson and Watson[2], indicates that it is possible to examine the lattices of easily denatured materials directly. The mechanism of image formation is similar to that proposed by Menter[8] for platinum phthalocyanine and the mineral sodium faujasite.

The results obtained here for the cell dimensions of type *F* myoglobin agree well with the results of Kendrew and Pauling. This indicates that the electron microscope can be used for providing reliable data for the evaluation of the crystal structures of materials difficult or impossible to study by X-rays.

I am grateful to Dr. J. C. Kendrew for supplying the myoglobin, Mr. R. Phillips and Dr. J. S. Halliday for their help and advice, and Dr. T. E. Allibone, director of the Research Laboratory, Associated Electrical Industries, Ltd., for permission to publish this article.

STRUCTURE OF SOME HYDROXIDES AND HYDROUS OXIDES

Binding of Water in some Hydroxides and Hydrous Oxides

INFRA-RED absorption spectra of hydrated aluminium oxides have recently[1] been interpreted as follows: these oxides contain hydroxyl groups, and on rehydration of the anhydrous oxides, these may be built into the lattice. In most cases no change in lattice of the oxides can be observed. The experiments were extended to compounds of the systems manganese dioxide/water[2], silicon dioxide/water and ferric oxide/water[3,4], and the presence of hydroxyl groups in these substances has been proved in the same way. We were interested in the brown precipitate formed in solutions of iron (III) salts by adding hydroxyl ions. These precipitates are either (incorrectly) formulated as $Fe(OH)_3$, or supposed to be iron (III) oxide with a very large specific surface[5]. In Fig. 1 the infra-red spectrum of a sample containing 15·1 per cent water is given, obtained from a solution of iron (III) nitrate by precipitation with ammonia, compared with the spectrum of water.

The centre of gravity of the hydroxyl band of water is located at 2·95μ. However, the centre of gravity of the band in I has moved to longer wave-lengths, between 3·1 and 3·2μ. Also an asymmetrical broadening to longer wave-lengths is observed. In I, therefore, we assume that the hydroxyl groups form O—H . . . O hydrogen bonds which are, in part, very strong because of the shorter O—H—O distance; the stronger these bonds are, the longer the OH absorption wave-length[6].

Proton magnetic resonance measurements have been carried out on aluminium and iron hydroxides and on manganese oxide hydrates (see following

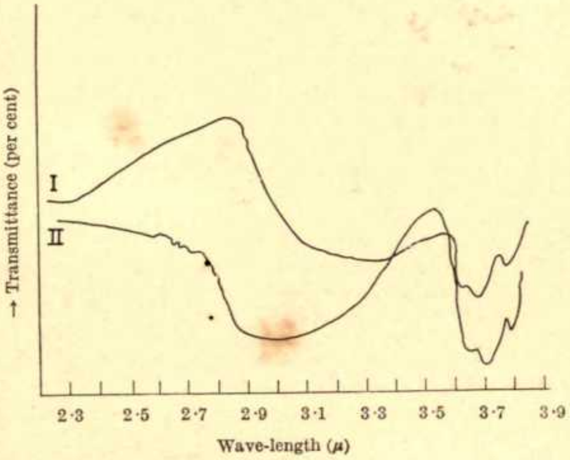

Fig. 1. Infra-red spectra (lithium fluoride prism, dispersion in 'Nujol') of iron (III) hydroxide (Fe_2O_3. 1·49 H_2O) and the spectrum of water

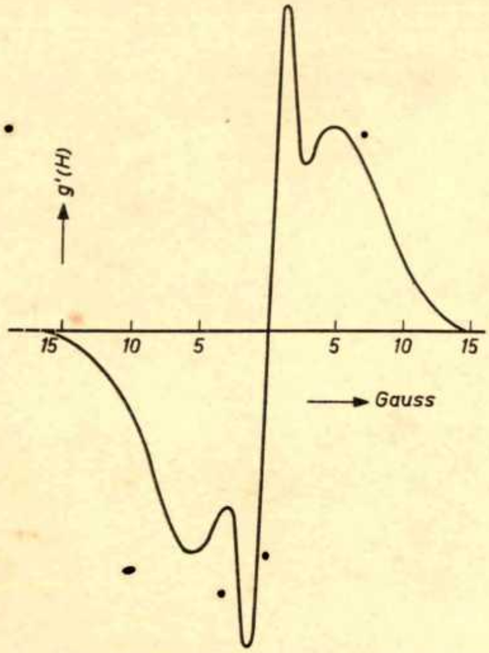

Fig. 2. Pseudo-differentiated absorption curve of boehmite (γ-AlOOH)

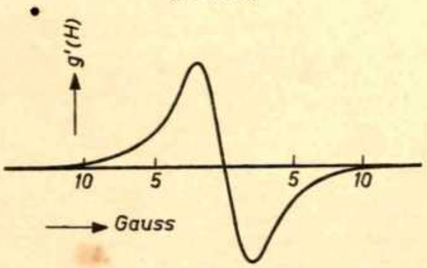

Fig. 3. Pseudo-differentiated absorption curve of an iron (III) hydroxide ($Fe_2O_3 \cdot 2{\cdot}72\ H_2O$)

communication). All aluminium oxides showed a broad line with a superimposed narrow line which is thought to be due to adsorbed water (Fig. 2). Table 1 summarizes the results for aluminium hydroxides. In general, the absorption signals of iron hydroxides and manganese oxides consist of a narrow line which is broadened at the base (Fig. 3).

Table 2 contains the results for iron (III) hydroxide gels and manganese oxides.

To obtain an absorption signal sufficiently large to permit measurement of the broad lines, it was necessary to choose a rather large field modulation (1·6 gauss). The tabulated values of the line-widths of the narrow lines are mainly determined by this modulation and are therefore too large. The tabulated percentage of adsorbed (free) water represents only a rough estimate in the cases where the narrow line and the broad base, which is thought to be due to bound water, strongly overlap.

Table 1. PROTON MAGNETIC RESONANCE RESULTS ON ALUMINIUM HYDROXIDES

Sample	Formula	Line-width (gauss)		Mole per cent 'adsorbed' water
		Narrow	Broad	
Hydrargillite	$Al_2O_3\ 3{\cdot}01\ H_2O$	2	14·3	0·8
Bayerite	$Al_2O_3\ 3{\cdot}18\ H_2O$	2·6	11·7	6
Boehmite	$Al_2O_3\ 1{\cdot}06\ H_2O$	2·6	10·5	6

Table 2. RESULTS OF MEASUREMENTS ON IRON (III) HYDROXIDE GELS AND MANGANESE OXIDE HYDRATES

Formula	X-ray data	Line-width (gauss)	Base-width (gauss)	Mole per cent 'adsorbed' water
$Fe_2O_3\ 2{\cdot}72\ H_2O$	Some broadened lines of α-Fe_2O_3	4	29	55
$Fe_2O_3\ 1{\cdot}72\ H_2O$	γ-FeOOH	4	29	40
$Fe_2O_3\ 1{\cdot}96\ H_2O$	amorphous	3·9	~33	43
$Fe_2O_3\ 1{\cdot}2\ H_2O$	amorphous	5·3	~25	25
$MnO_{1{\cdot}93}\ 0{\cdot}86\ H_2O$	δ-MnO_2	2·1	11	60
$MnO_{1{\cdot}93}\ 0{\cdot}21\ H_2O$	γ-MnO_2	2·2	25	40

Table 2, as well as the infra-red spectra, show the impossibility of isolating precipitates with the formula $Fe(OH)_3$ from solutions of iron (III) salts by the addition of hydroxyl ions. Probably the hydroxyl groups condense with the formation of water, and this may occur during aging or heating via compounds with gradually decreasing water content, until the water-free end-product, α-Fe_2O_3, is formed.

On one hand, the existence of hydroxyl groups in manganese oxide supports the suggestion of Feitknecht and Marti[7] that the deviation of the oxygen content from the ideal stoichiometric formula $MnO_{2{\cdot}00}$ arises from the replacement of oxygen ions by hydroxyl ions. On the other hand, it is difficult to consider samples with a higher hydroxyl content, for example δ-MnO_2, as polymorphic modifications of manganese dioxide.

Our results on the compounds belonging to the oxide/water system suggest two new groups of hydroxides: (1) *condensed hydroxides* resulting from the elimination of water, for example, iron (III) hydroxides, silicic acid; (2) *non-stoichiometric hydroxides* with non-stoichiometric hydroxyl contents, for example, aluminium hydroxides with different hydroxyl contents in identical lattices.

The proton magnetic resonance experiments were carried out at the Philips Research Laboratories in Eindhoven.

Positions of Protons in Aluminium Hydroxides derived from Proton Magnetic Resonance

PROTON magnetic resonance measurements have been carried out on some aluminium hydroxides with the object of ascertaining whether the water was present in free (for example, adsorbed) or in bound form (see preceding communication). All samples consisted of powdered material. The measurements were carried out at room temperature with a simple nuclear magnetic resonance spectrometer of the autodyne type (to be published). The resonance absorption of protons was determined at a frequency of 17·5 Mc/s.

From the second moment of the absorption line $g(H)$ defined as:

$$\int_{-\infty}^{+\infty} g(H)\,(H - H_0)^2 \mathrm{d}H \Big/ \int_{-\infty}^{+\infty} g(H)\mathrm{d}H$$

information may be obtained about the positions of the protons in the crystal lattice[1]. In Table 1 the calculated values of the second moment are given, assuming a certain model as well as the second moment derived experimentally from the broad line (see preceding communication). The second moments of the aluminium oxide hydrates were calculated as follows.

Table 1. CALCULATED AND EXPERIMENTAL SECOND MOMENTS OF THE ALUMINIUM HYDROXIDES STUDIED

Sample	Second moment calculated (gauss^2)	Second moment experimental (gauss^2)
Hydrargillite	26·0	26·5 ± 1·2
Bayerite		18·8 ± 1·0
Boehmite	19·0 – 19·2	18·2 ± 1·0

Hydrargillite ($\gamma Al(OH)_3$). The structure of hydrargillite has been determined by Megaw[2]. In this structure the aluminium atoms are located between two planes of oxygen atoms which are close-packed and surround the aluminium atoms octahedrally. These planes form an *AB—BA—AB—B* . . . sequence. According to Megaw, the protons are found between these 'sandwiches'.

Fig. 1 shows the octahedron triangles formed by the oxygen atoms in one plane.

One may assume a model where the O—H bonds are directed from an oxygen atom in the lower plane to an oxygen atom in the upper plane in the next 'sandwich', but translated over one triangle side. In alternate triangles these OH bonds are pointing upward and downward (Fig. 1*a*). From this model a second moment of 26·0 gauss^2 is calculated (taking the OH distance equal to 0·96 A.). In a similar model (Fig. 1*b*), with the projections of the OH directions in the different triangles forming an angle of 120°, one obtains 29·4 gauss^2. In these models it is clear that there exists a special triangle in agreement with the X-ray data. It will be shown elsewhere that from other models a completely different value of the second moment is obtained. (For example, for the model suggested by Bernal and Megaw[3] the second moment is less than 15 gauss^2.)

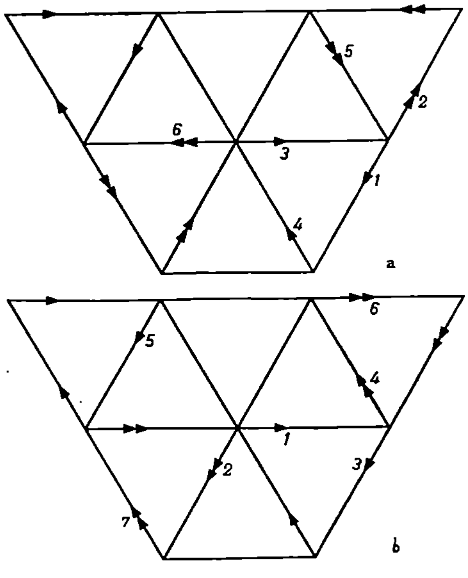

Fig. 1. Octahedron triangles of the oxygen atoms of one layer of hydrargillite: single arrows, OH bonds pointing upward; double arrows, OH bonds pointing downward

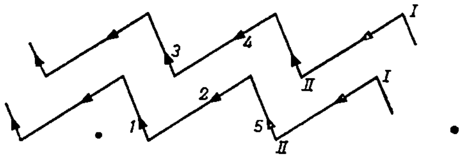

Fig. 2. Zigzag chains of the OH bonds in boehmite in the parallel position

The calculations on hydrargillite were carried out starting from a regular hexagonal structure. In practice, the octahedra are slightly deformed; the effect upon the second moment is small.

Boehmite ($\gamma AlOOH$). The structure of boehmite has been determined by Millikan and McAtee[4]. The OH directions form zigzag chains between the planes of the oxygen atoms (Fig. 2). Nakamoto, Margoshes and Rundle[5] have correlated the OH-stretching frequency and the O—H . . . O distance in different compounds. They give a graph of O—H distances against corresponding O—H . . . O distances. In this graph an O—O distance of 2·70 A. corresponds to an O—H distance equal to 0·98 A. With an assumed OH distance of 0·98 A. a second moment of 19·0 gauss^2 is obtained in the case of parallel OH bonds in successive chains, whereas for anti-parallel OH bonds one obtains 19·2 gauss^2. It is thus not possible from values of the second moment alone to distinguish between these models.

After the work described here had been completed, a recent paper of Holm *et al.*[6] came to our attention, giving experimental data and calculations of the structure of boehmite in complete agreement with our results.

Bayerite (α-$Al(OH)_3$). The structure has been determined by Yamaguchi and Sakamato[7]. They assume a model not unlike the structure of brucite, $Mg(OH)_2$, but without one-third of the metal atoms. However, the calculation of the second moment for this structure leads to values larger than 33 gauss^2. (The OH distance was assumed to be 0·98 A.)

The discrepancy between the experimental and calculated second moments is so large as to suggest a completely different structure.

We thank Prof. O. Glemser, of the Anorganisches Chemisches Institut der Universität at Göttingen, for preparing the samples.

ACTION OF AUXINS ON *ACETABULARIA* AND THE EFFECT OF ENUCLEATION

By PROF. KENNETH V. THIMANN and DR. KURT BETH

Harvard University Biological Laboratories, Cambridge, Mass., and Stazione Zoologica, Naples

THE effect of auxins on algæ has never been as clear-cut as on higher plants. While some positive effects, both on multiplication of unicellular forms and on organ formation in larger algæ, have been demonstrated, many of the results have been uncertain or even conflicting. In the case of *Chlorella*, some, but not all, of the disagreement may have been due to the use of ethanol as solvent for the added auxin, since concentrations of ethanol as low as 0·01 per cent markedly increase the growth[1,2]. However, there are other sources of variation; Elliot[3] found indoleacetic acid, made up without alcohol, to promote the growth of *Euglena gracilis* at 0·1–1·0 mgm./l., while in our own (unpublished) experiments no effect could be found at any concentration with autotrophic or mixotrophic nutrition. Other factors were uncovered by Algeus[4], who has made the most thorough study to date with unicellular forms. He found indoleacetic acid (made up without alcohol) caused marked increases in cell number in two strains of *Chlorella* and in *Scenedesmus obliquus*, but not in others. There was no increase in cell size. Naphthaleneacetic acid and indole-3-butyric acid were much less effective than indoleacetic acid. He observed that the stimulation in indoleacetic acid came to an end after about six days, and traced this to photo-destruction of the auxin and consequent formation of an inhibitory product; the product of the action of hydrogen peroxide on indoleacetic acid was also inhibitory. Algeus and other workers have also reported that when sugar was added to the medium the growth is better, but the promoting effect of auxin disappeared. Presence or absence of sugar, like that of ethanol, may explain some, though not all, of the earlier discrepancies. A comparable influence of soil extract has been noted in our work reported here.

Work on the larger algæ is somewhat more definite. The growth of germinating zygotes of *Ulva*, zoospores of *Enteromorpha*, and sporelings of *Fucus* and *Ascophyllum* are all reported to be promoted by indoleacetic acid[5,6], but in the case of *Fucus* sporelings iodoacetic acid was about equally effective; the stock solutions were made up with alcohol in this case[6]. In the green alga *Rhizoclonium*, indoleacetic acid caused marked elongation, the mean cell-length being doubled at the optimal concentration, which was 10^{-9} M; the dry weight showed a smaller increase[7]. Again the stock solutions were made up in alcohol, which may vitiate these results. However, isolated apical segments of *Codium* gave a marked elongation response to 5 mgm./l. (3×10^{-5} M)[8] of indoleacetic acid, and this solution contained no alcohol. Organ formation may be promoted, too; the development of rhizoids on the thallus of *Bryopsis*[9] and *Enteromorpha*[10] was strongly promoted by indoleacetic acid, though Jacobs's method of application (suspension of a few indoleacetic acid crystals in the sea water) probably involved very high concentrations[9]. Indoleacetic acid hastened both shoot and rhizoid development on separated internodes of *Nitella*[11,12], but the action of other auxins was equivocal: naphthaleneacetic acid hastened formation of rhizoids but not that of shoots, indolebutyric acid hastened that of shoots but not that of rhizoids, while 2,4-dinitrophenol hastened neither. The effects were quite non-specific since riboflavin and ascorbic acid were about equally active; pyridoxin and niacin were also active on rhizoid formation. Another apparently non-specific effect is that of indoleacetic acid, kinetin or adenine in promoting the initiation of filaments on the thallus of *Ulva lactuca*[13]. Recently, Hustede[14] has found a striking effect of indoleacetic acid in promoting the formation of zoospores of *Vaucheria* and causing its antheridia to grow into vegetative tissue. Tryptophan has the same effect, but indolecarboxylic acid acts in the opposite direction, suppressing the formation of zoospores and promoting the formation of oogonia. Finally, Dao[15] has reported marked acceleration of growth by indoleacetic acid in *Acetabularia mediterranea*; but the effects varied with the season. Later, however, she could not confirm these results, either with indoleacetic acid or naphthaleneacetic acid, though high concentrations of the former or tryptophan still promoted growth somewhat[16]. The solutions were not changed during the experiments and became brownish due to photodestruction (cf. ref. 4). As actual growth data were not given, and the ranges of growth-rate quoted were higher for her plants growing in unsupplemented sea water than for those of other workers in the more favourable Erdschreiber solution, it is difficult to appraise this work.

The general impression from these studies is that some aspects of algal growth are indeed promoted by auxins under some conditions, but that these conditions are not well defined, the specificity of the action is uncertain and the effects are subject to wide variation. Since many processes in algæ are fundamentally the same as in higher plants, and since there is no special reason for believing that the processes of growth constitute an exception, promotion by auxin should be expected. It seemed, therefore, desirable to re-examine the problem. In the microscopic forms, cell multiplication is the only convenient criterion for growth, whereas in higher plants the most prominent effects of auxin are on cell enlargement and organ formation. For this reason an alga with large cells was preferable. The specially favourable structure and long growing period of *Acetabularia*, as well as the marked morphogenetic capacities of its parts, which have been the subject of numerous investigations, made it peculiarly well adapted for the purpose.

Plants of *Acetabularia mediterranea*, 6–9 months old and 10–30 mm. in length, were the experimental material. They were grown in Erdschreiber solution, and the experiments were carried out in artificial-light cabinets at 20° C. Erdschreiber, Schreiber solution, or sea water were used as a medium, and indoleacetic acid, naphthaleneacetic acid, or in a few cases other compounds, were used as auxins. The stock auxin solutions, from which dilutions were prepared, were made up in sea water and adjusted to pH 8·0–8·2.

Two different and independent effects of auxins on *Acetabularia* have been established in this work. They are complexly interrelated with both the simultaneous and the previous exposure of the plants to light, as well as with the nutrient solution used. In the first place, indoleacetic acid promotes elongation of the stalk. The effects range up to nearly 100 per cent increase: they can be observed in both bright and medium light, and are best seen in Schreiber's solution. The optimal concentration of indoleacetic acid is from 10^{-5} to 10^{-6} *M* (1·75–0·175 mgm./l.). An example is shown in Table 1.

Table 1. GROWTH OF INTACT *Acetabularia* PLANTS IN INDOLEACETIC ACID

Bright light, 20° C., Schreiber solution. Plants which had formed caps at 25 days omitted

Concentration of indoleacetic acid (*M*)	0	10^{-6}	10^{-5}	10^{-4}
Initial length (mm.)	19·8	20·3	19·0	19·9
Increase in next 11 days (mm.)	1·7	2·8	4·4	4·5
Increase in following 14 days (mm.)	5·2	5·0	8·7	7·2
Total increase in 25 days	6·9	7·8	13·1	11·7

In the second place, indoleacetic acid promotes the formation of the 'cap' (the organ in which the reproductive cysts are formed later). This also can be observed best in Schreiber solution, but has been noted to a lesser extent in Erdschreiber, in which all the plants, controls included, form caps more readily. The optimum concentration of indoleacetic acid for cap formation is in most experiments 10^{-4} *M*, that is, 100 times as great as for elongation. One of several comparable experiments is shown in Fig. 1.

Naphthaleneacetic acid also acts powerfully on cap formation; its optimum concentration is at 10^{-5} *M*, while 10^{-4} *M* is inhibitory and eventually toxic. It is thus clearly effective at lower concentrations than indoleacetic acid. In promoting stalk growth its optimum concentration is 10^{-5}–10^{-6} *M*, though it is apparently somewhat less potent than indoleacetic acid.

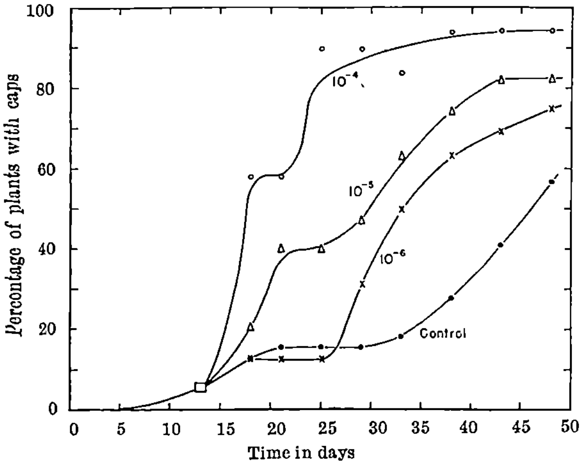

Fig. 1. Time course of cap formation in *Acetabularia mediterranea* at 20° and about 100 ft. candles white light; in Schreiber solution and with three concentrations of indoleacetic acid, 10^{-4}, 10^{-5}, 10^{-6} *M*, renewed about every 7 days

A feature of the responses, both in stalk growth and in cap formation, is that they occur only after a considerable period of time, 10 days being about the minimum for a detectable effect. Since the pH of the suspending medium is about 8·2, a value at which indoleacetic acid and naphthaleneacetic acid are fully dissociated and therefore might perhaps be restricted in their entry, a study was made of the action of the neutral auxins methyl indoleacetate and indoleacetonitrile. However, while both these substances clearly promote cap formation, and in addition the nitrile promotes elongation, their action was found to be no more rapid than that of indoleacetic acid. Indeed, the elongation caused by the nitrile was not observed at all at 11 days, when indoleacetic acid had shown a pronounced effect, but was only seen after 28 days. The slow action of the acidic auxins is not, therefore, due to slow entry into the plant.

That the slow action is also not due to photodestruction (cf. Algeus[4]) follows from the fact that the action of naphthaleneacetic acid, which is resistant to photo-destruction, is no more rapid than that of indoleacetic acid. To make this point certain, however, an experiment was carried out with the latter acid in which the solution was changed daily, instead of every 5–7 days as in the other experiments. There was no marked increase in the growth promotion, nor did it begin earlier. The slow reaction thus seems to be a characteristic of the system under study.

A substance which antagonizes the action of auxin in some assay systems, though not in all, is 2,3,5-triiodobenzoic acid. This compound was found to inhibit both elongation and cap formation. The effective concentration was 10^{-4} *M* and higher levels were toxic.

The isolated rhizoids (which contain the nucleus) behave somewhat differently. So far as auxin is concerned, the rhizoids are in most cases inhibited in elongation by added auxin at all levels down to 10^{-7} *M*. However, after the plants have been removed from the auxin solution and returned to unsupplemented Schreiber solution, they may afterwards show a striking growth promotion which lasts for several weeks. This is illustrated in Fig. 2. Such different behaviour to auxin by different parts *of a single cell* is of considerable interest.

The facts: (1) that the concentrations of auxin effective for the two actions are different and (2) that in some experiments, especially with methyl indoleacetate, cap formation was clearly promoted while elongation was not, suggest strongly that elongation and cap formation are independent processes. This supports previous conclusions as to their independence, based upon the evidence that cap formation is mediated by specific substances[17–19] and on the very different light-intensity requirements of the two processes[20].

It is well known that the addition of soil extract to sea water or to Schreiber solution ('Erdschreiber') promotes both growth and cap formation. This effect is evidently not the same as the action of auxin, as the following experiment shows. A group of plants in sea water with added naphthaleneacetic acid in a series of concentrations formed 55 per cent of caps in the optimal concentration (10^{-5} *M*)—a figure which

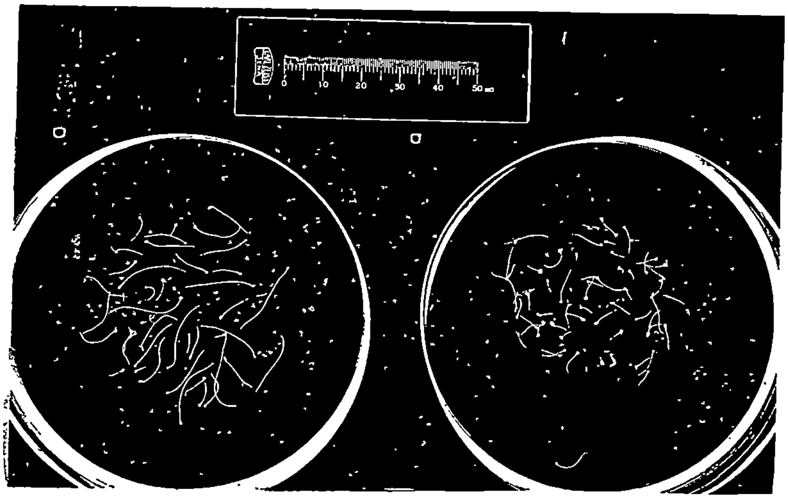

Fig. 2. Isolated rhizoids from plants pre-treated with indoleacetic acid 10^{-5} *M*, grown afterwards in Schreiber solution for 20 days

did not increase further in an additional 6 weeks. At this point Erdschreiber solution was added. Within one week the percentage of caps had risen to 90 per cent. Comparable increases occurred in the other concentrations. It is suggested that soil extract and auxin act upon essentially the same process but in different ways.

Some of our experiments point also to the probability that in bright light a growth-limiting factor is used up or destroyed, but that this factor can be synthesized from the constituents of Erdschreiber solution. This light-labile growth factor also cannot be identical with auxin.

Effect of Enucleation

Since in *Acetabularia* the single primary nucleus lies in the rhizoids, another, and a long-standing, problem of auxin action could be attacked. Many attempts have been made to demonstrate an action of auxin on *in vitro* systems, but always without success. In consequence, it appears that the intact cell is necessary for auxin action, and this has led to the speculation by one of us that the primary action of auxin may be exerted on the nucleus, which then secondarily modifies enzyme systems controlling growth. *Acetabularia* is one of very few organisms in which this proposal can be readily tested, because its enucleated cells can be easily prepared and they have been shown to survive well and even to grow. The action of auxin was therefore studied on enucleated *Acetabularia*. The part cut off in these experiments comprised the whole rhizoid plus about 1 mm. of stalk.

Enucleation slows down elongation very greatly. This fact, although mentioned by Hämmerling in 1934[17], does not seem to have been clearly brought out in subsequent work. However, the growth of enucleated plants is still readily measurable. From our experiments it seems clear that they still show some growth promotion in response to auxin, though the responses are smaller than those in intact plants. For example, elongation of enucleated plants (30 mm. long) in 3 weeks was increased from 2·6 mm. in the controls to 4·7 mm. in 10^{-4} *M* indoleacetic acid. Furthermore, the percentage of caps was increased from 14 (controls) to 44 (indoleacetic acid) in the same period. As an average of four experiments in Schreiber solution, cap formation in enucleated controls was 14 per cent and in optimal auxin 31 per cent (final figures reached); in an additional two experiments, however, there was no response to auxin. On the whole, it seems clear that indoleacetic acid does promote cap formation in enucleated plants, and it increases not only the rate of formation but also the final number of caps. In most cases a higher auxin-level was needed for the optimum effect in enucleated than in intact plants.

Additional evidence is supplied by the finding that triiodobenzoic acid, 10^{-4} *M*, inhibits strongly the formation of caps by enucleated plants. It can be concluded that both auxin and an auxin antagonist are able to act on the cytoplasm. Whether or not the nucleus makes the action more effective must be left open.

In general, our experiments indicate that auxin plays a growth-promoting part, rather than being itself one of the previously postulated morphogenetic substances. Since it does not increase cap formation when applied to old plants which have already begun to form caps, it cannot be the cap-forming substance itself. It cannot be the precursor which is converted to cap-forming substance by bright light[19,20], because if so it should always (in optimum concentration) produce 100 per cent caps in bright light. For the same reason it can scarcely be any earlier intermediate in the chain. Therefore it must act only to promote one or more of the reactions leading to cap formation. This role is comparable with the influence of externally applied auxin on elongation in *Acetabularia*, which is also only a promotion. The part played by endogenous auxin in these reactions will be a subject for further study. In the meantime, the fact that these effects can occur, albeit to a limited extent, in the absence of the nucleus, seems to us of importance for theories of auxin action.

This research was carried out during the tenure of a Guggenheim Fellowship by one of us (K. V. T.). Use of the facilities of the Naples Marine Station, and the helpful co-operation of the director, Dr. R. Dohrn, and his staff are gratefully acknowledged.

Fluorescence Effects from Corals irradiated with Ultra-Violet Rays

In January 1957, three months after the official inauguration of the Aquarium of Nouméa which my wife and I established in New Caledonia, we obtained the first effects of fluorescence through irradiation with ultra-violet rays of deep-water corals. The different specimens treated had been collected in the lagoon at a depth of 35–40 m., about twenty miles from our station where they are kept alive.

The first corals on which we experimented belonged mainly to the genus *Flabellum*, with which we obtained green fluorescence of great intensity. (There is no doubt that it is fluorescence, as the phenomena stop as soon as the excitation ceases. In other words, there is in these corals no residual photoluminescence, which becomes apparent as soon as the irradiation ends.) Since then, all specimens of corals, collected in the same region and elsewhere from varying depths, have been systematically exposed to treatment with ultra-violet radiation.

Our preliminary observations are as follows: (1) Only a certain number of species respond to irradiation. (2) All individuals belonging to the same genus produce generally the same colour of fluorescence (thus the *Flabellum* show greens, the *Trachyphyllia* oranges, etc.). However, certain genera may present several colours in the same individual. In that case a particular colour is always localized in the same region on each organism. (3) Colours and frequency-range are, at present: green, varying from light to dark, and at times with a glow; orange, varying from light to dark and at times with a brilliant glow; silver blue (very small range); reddish (either dull or shiny); beige (very small range); brown (very small range); and grey (sometimes silvery).

The definite green colour of certain corals may sometimes change to pink either after frequent or too lengthy exposures to irradiation or perhaps from other causes. (4) Only the fleshy parts of corals are fluorescent; the skeleton itself never reacts. (5) The expansion of polyps of certain species, especially those which expand normally in day-time, is greatly excited by ultra-violet irradiation, while species which expand at night do not react positively. (6) Most corals exposed to ultra-violet irradiation suffer from this treatment. In certain cases it may be fatal if the experiment is repeated too often or if it is of too long duration. Generally speaking, the intensity of fluorescence decreases day after day in proportion with the decreased vitality of the subject treated.

Other organisms collected from a depth of 35–40 m., particularly anemones and calcareous algae, show fluorescence, but its intensity is much less than that observed with corals.

Apart from the exceptional beauty of the fluorescent corals, the phenomena suggest research in different fields such as chemistry, physics and biology. Finally, this fluorescence might be a new approach to the systematic study of these corals. In fact, certain specimens which seem *a priori* to belong to the same species react to ultra-violet irradiation with quite different colours.

Lumpy Skin Disease of Cattle in Kenya

Lumpy skin is an infectious disease of cattle characterized by the eruption of cutaneous nodules on any part of the body together with generalized lymphadenitis. It has been known for some time in several African territories, including Northern Rhodesia (1929)[1,2], Bechuanaland (1943)[3], the Union of South Africa (1944)[4], Southern Rhodesia (1945)[5], Mozambique (1946)[6], Swaziland (1946)[7], Basutoland (1947)[7], Madagascar (1954)[8] and Belgian Congo (1955)[9]. The dates of first confirmation in these countries are in parentheses.

To the above list must now be added Kenya, where the disease was recognized for the first time towards the end of 1957 on a farm in the Nakuru area. The source of infection in this outbreak is unknown. The disease was confined to calves, some of which were severely affected. The natural mortality was very low, and all active cases were slaughtered. After confirmation of the initial outbreak, field staff of the Veterinary Department carried out an extensive and systematic search for further cases of the disease over a wide area of the surrounding districts. Only a few active cases were found on widely separated farms. These were generally mild in character, and involved, as a rule, only one or two animals in each herd. Over the past year lumpy skin disease has spread slowly and sporadically despite the enforcement of stringent quarantine restrictions and sanitary arrangements. Cattle on recently affected farms in the vicinity of Lakes Nakuru and Elmenteita, however, have shown a higher morbidity, and individual cases have been more severe.

In Kenya, as in other affected territories, the spread of the disease has been unaccountable. Outbreaks have occurred in herds several miles apart with no evidence of infection on neighbouring or intervening farms. There was severe infestation by mosquitoes on the first farm where the disease was diagnosed. Infestations of varying severity have also been reported on 54 out of 56 farms afterwards infected by lumpy skin disease. The possible role of mosquitoes as vectors of the disease is under investigation.

In the more severe cases in Kenya nodules have been found not only in the skin but also in the internal organs, for example, oral cavity, pharynx, larynx, trachea, lungs, liver and proventriculi. Histological examination of skin and other lesions has revealed the presence of intracytoplasmic inclusions in a large proportion of cases in the epithelial and infiltrating mononuclear cells similar to those first described by Thomas and Mare[4].

Alexander *et al.*[10] have isolated three types of infective agents from cases of lumpy skin disease. One of these, their group II, produces a generalized response on the part of susceptible animals with the development of nodules over practically the entire body following subcutaneous inoculation of virus. In tissue-culture monolayers this agent gives rise to the rapid formation of large syncytia and the development of large intranuclear inclusions. Agents of this type have not, so far, been isolated in Kenya. Another type of agent, group III, rarely produces generalized skin eruptions on inoculation of susceptible cattle. In tissue culture the cytopathic changes develop more slowly than those of the first type and the inclusions are intracytoplasmic. Seven separate isolations of agents of this type have been made so far in this Laboratory from different farms, including the farm originally infected.

In addition there have been five isolations of a type of agent from active cases of the disease which gives rise to characteristic cytopathogenic changes in cell cultures but which elicits no clinical response whatsoever on inoculation of susceptible cattle. In this respect these resemble the agents of Group I as described by Alexander *et al.*[10].

Fuller details of the work carried out so far on lumpy skin disease in this Laboratory will be reported shortly.

We are grateful to the Director of Veterinary Services for permission to publish this preliminary communication.

Records of Young Eels in Kenya Rivers

Frost[1] published the first account of the biology of freshwater eels in Kenya. She showed that, of the three species of eel found in the easterly flowing rivers, *Anguilla nebulosa labiata* Peters is the most abundant above 3,000 ft.; *A. mossambica* Peters is comparatively rare, and *A. bicolor bicolor* McClelland is both uncommon and apparently restricted to the lower reaches of rivers. Our own (unpublished) records from the lower Sabaki (Athi) River and from upper tributaries of the Tana River confirm this distribution.

The elvers of *A. mossambica*, the common South African eel, are now well known, and runs up the Buffalo River (Eastern Cape) in February and March have been recorded for three successive years[2-4]. Recently, the elvers of *A. b. bicolor*, known previously only from Madagascar, were found at sea-level in the Mzinga River near Dar es Salaam (Tanganyika) in late January and mid-February[5]. With these elvers were two which could be referred to *A. n. labiata*, the first to be recorded. But apart from two rather damaged early stages (165 and 115 mm.) collected by Frost[1], the largest of which she tentatively assigned to *A. n. labiata*, there have been no records of elvers or young eels in Kenya rivers.

Table 1

Source	No. of specimens	Total length (mm.)	Ano-dorsal fin ratio		Vertebral count†
			Elvers	Adults*	
A. Merilla Barrage (Tana River) April 24, 1958	18	104–161	9·7–13·4	10·0–14·9 (*A. n. labiata*)	105–108
B. Jilore (Sabaki River) Nov. 1956	1	87·5	11·4	14·6 (*A. mossambica*)	91

* Based on Frost's Kenya collection (unpublished).

† Counts determined in *A* by dissection (one) and by X-ray photographs (five); in *B* by X-ray only.

In June 1957 we received reports of numerous 'elvers' having been found among the debris caught up in the draft tubes of the turbines at the Tana Hydro-electric Power Station on the Tana River, at an altitude of approximately 3,800 ft. (0° 40′ S.; 37° 14′ E.). Unfortunately no specimens were kept. However, further investigation in the vicinity of the power station in April 1958 produced eighteen young stages of eels which had been trapped in the syphon-priming chamber of the dam serving this power station (the Merilla Barrage), the construction of which device enables it to function as a very efficient elver trap. Subsequent visits have proved negative, but more young stages are expected in the appropriate season, which is probably during the 'long rain' floods of March–May in this area. The total lengths of the young eels (104–161 mm.) are considerably larger than the lengths of elvers recorded by Frost[5] at sea-level, suggesting that they are in fact post-elvers. Although apparently caught while migrating upstream, there is no indication of their date of arrival at the Tana River mouth, some 300 miles to the east, and it is also possible that they had remained in the priming chamber for some time. We have also been able to examine a much smaller eel (87·5 mm.) caught in a native basket-trap at Jilore on the Sabaki River (3° 8′ S., 40° 4′ E.) by Mr. John Kadenge, this locality being only 20 miles from the sea at an altitude of 100 ft. There is some doubt regarding date of capture, but it is believed to have been trapped during the 'short rain' floods of November 1956.

Adults of the three Kenya species of eel can be separated on the basis of dentition, coloration, the ano-dorsal fin origin formula used by Frost[1], and vertebral counts. These characters are not entirely satisfactory for the young stages, although vertebral counts are probably the most reliable.

Coloration. The eighteen Tana River eels were distinctly mottled, as are the adults of *A. n. labiata*, but after preservation in formalin or alcohol only the largest retained this coloration. The single Sabaki River elver, first inspected after about 18 months in formalin, showed a light peppering of chromatophores above the mid-lateral line, but no suggestion of mottling.

Dentition. As in adult *A. n. labiata*, the largest Tana River eels appear to have a slight groove between the lateral rows of teeth in both jaws, but in the smaller specimens and in the Sabaki River elver the teeth are rather irregularly placed.

(*Continued on p.* 971)

Supplement to NATURE

No. 4666 APRIL 4, 1959 Vol. 183

FROM DAN TO BEERSHEBA: EXCAVATIONS IN NORTH AND SOUTH PALESTINE

Lachish (Tell ed-Duweir) IV

The Bronze Age. By Olga Tufnell. With contributions by D. F. W. Baden-Powell, Dorothea M. A. Bate, Jaroslav Černý, David Diringer, Madeleine Giles, Hans Helbaek, B. S. J. Isserlin, Margaret A. Murray, Barbara Parker, Edith Porada, F. C. Thompson, Eric Todd and John Waechter. Text: Pp. 351. Plates: pp. 6+96 plates. (The Wellcome-Marston Archæological Research Expedition to the Near East.) (London: Oxford University Press, 1958. Published for the Trustees of the late Sir Henry Wellcome.) 168*s*. net (text and plates).

Hazor I

An Account of the First Season of Excavations, 1955. By Yigael Yadin, Yohanan Aharoni, Ruth Amiran, Trude Dothan, Immanuel Dunayevsky and Jean Perrot. (The James A. De Rothschild Expedition at Hazor.) Pp. xxiv+160+184 plates. (Jerusalem: At the Magnes Press of the Hebrew University; London: Oxford University Press, 1958.) 168*s*. net.

THE appearance of Lachish IV brings to a close the immense task of publishing the results of six seasons of excavations at Tell ed-Duweir in southern Judea, and Miss O. Tufnell and her collaborators are to be warmly congratulated on their achievement. The excavations themselves ended in 1938 with the tragic death of their director, J. L. Starkey, and since then it has been the task chiefly of Miss Tufnell to gather together the records of the work and present them to the public. Previous volumes have given accounts of the Biblical city, the Canaanite temple, and of important epigraphic material. The present volumes trace the history of the *tell* itself and the neighbouring cemeteries from the Chalcolithic period until the destruction of the city by Israelites or Philistines about 1200 B.C. Although the only important structure described is the Middle Bronze Age glacis defence system, a wealth of material from the Early, Middle and Late Bronze Ages is carefully analysed, and an outstanding contribution is made to our knowledge of south Judean civilization during the third and second millennia B.C.

The most interesting sections deal with what Miss Tufnell calls the 'Caliciform culture' (Albright's Middle Bronze I, and Miss Kenyon's Intermediate Early–Middle Bronze). Miss Tufnell prefers to see in the differences between various groups of Caliciform pottery evidence for a chronological succession, rather than for different ethnic groups, as Miss Kenyon has suggested at Jericho. If the "straggling house walls" of the north-west settlement (p. 42) really belong to this period, then their plan (Plate 95) lends support to this theory, since they obviously belong to several superimposed building phases. It is a pity that these phases are not noted or analysed in the report.

It is not to be expected that this is an ideal publication. An interval of twenty years between excavation and report is too long, and Miss Tufnell has had to cope with another archæologist's records, which were, plainly enough, in many cases inadequate. The treatment of the north-east section, for example, is very sketchy, as is the drawing of the section itself, and consequently the discussion of the development of pottery types lacks that close stratigraphic control which is essential. In this respect the charts (Figs. 2–5) are especially suspect; sherd No. 123, for example (Fig. 3), from the 22-ft. level of the Middle Bronze glacis fill, looks very like a Chalcolithic bowl-rim. So, too, the references to the earliest material from Duweir—a Natufian end-scraper, a Neolithic painted sherd, and a grooved stone of Mesolithic/Neolithic type—are tantalizingly brief. There is enough evidence here to suggest that at the base of the mound the remains of a Neolithic community still lie buried.

The weakest point of the Lachish report lies in its arrangement. The student looking up comparative material is sent from page to page by a confusing series of cross-references and repetitions. Thus, there is a partial discussion of the Caliciform culture on p. 31 and a second, with new remarks, on p. 41; while the important group 1529 is treated on both p. 42 and p. 171 ff., and other groups of the same period on p. 153 ff. Similarly, on pp. 132–33 Prof. Černý reports on the Egyptian hieratic inscription on Lachish bowl III, while another opinion by Sir Alan Gardiner is quoted on p. 37. This leads to confusion and unnecessary labour.

Nevertheless, Miss Tufnell deserves great praise for publishing the material and records, however scanty, of this excavation. For many years to come these volumes will be one of the most important sources for the archæological history of Palestine. Their format is of the usual high standard of the Oxford University Press. I would make only one criticism: the form "ist", "iind", etc., for "1st", "2nd", is, to my mind, extremely ugly.

Tell el-Qedah is by far the largest (185 acres) ancient site in Palestine, and guards the main northern cross-roads in the Huleh plain. Its importance as the centre of Canaanite civilization in the north can be gauged from the number of times it is mentioned in Egyptian, cuneiform and Hebrew texts, and Dr. Y. Yadin and his army of assistants have now uncovered an impressive amount of the remains of this civilization, together with equally important remains of the Israelite period. Deserving of special mention are the pillared building of the time of Omri and Ahab (ninth century B.C.), the eighth century citadel, and the Late Bronze Age shrine, which, with its steles and cult-objects, throws a flood of light on Canaanite art and religion.

The wealth of archæological material found is here superbly presented, and this attractive volume is a credit to the Israeli printers and publishers responsible for it. I doubt, however, whether it is altogether wise to publish on so lavish a scale the results of the first of a series of excavation seasons. Dr. Yadin is himself aware of the drawbacks (p. xix), but considers them to be outweighed by the advantages of prompt publication. One cannot help feeling, however, that most of the important material could have been published in a series of more modest preliminary reports, leaving the final discussion of the major structural remains to a later date. An excavator's appreciation of the significance of his discoveries and of the history of his site must continually change with every new find. Even in Hazor I the evidence of later seasons is incorporated into the discussion at several points, for example, in the case of the Late Bronze Age shrine, while, conversely, the analysis of certain strata is left incomplete, to be discussed in a future volume. Promptness in publication is an admirable aim, but not if it means unnecessary duplication, especially when volumes are 8 guineas each.

Dr. Yadin's method of elucidating the history of Hazor has been to divide up his excavated areas vertically into a number of strata, each containing a complex of contemporary buildings. The criteria for establishing contemporaneity seem to be the plans of the buildings and the absolute levels of their floors. The strata are dated by the objects found therein. This method has undoubtedly established the broad outlines of the chronology of Hazor; but the treatment is really not as detailed as it could have been. Within any one stratum there are bound to be a number of sub-phases, which here usually pass unremarked. For example, the plan of area *A*, stratum VI (Plate CLXXIII) suggests that locus 76 was originally an open space between two buildings, and that the northern wall is a later addition. The exact sequence in this area could only have been ascertained by a much closer observation of the stratigraphy than the published report indicates. Again, it is axiomatic that all the material from one 'stratum' is not of equal value for the dating of that stratum. The pottery lying on the floor of a house will date from the last period of its occupation; the pottery from the deposit between one house and another above it may, according to whether that deposit is a destruction debris or a deliberate filling, either date the destruction of the lower house or the construction of the upper; while the latest sherds from the foundation trenches of a building will usually date its construction. Very seldom, if at all, are foundation trenches mentioned in this report. Pottery is said to come from a given locus, which is sometimes described as a room, a wall, a floor, etc.—sometimes, even, as 'undefined'—while the important fact, whether it comes from occupation material, debris, a deliberate filling, etc., is rarely stated. A curious instance of this failure to appreciate the significance of the exact provenance of finds occurs in the discussion of shrine I*A*, in area *C*. On p. 91 it is stated that a Cypriot milk-bowl of White Slip II type is one of the most significant sherds for dating the shrine. This bowl comes from locus 6062, which the plan (Plate CLXXX) shows to be a spread of small stones overlying wall 6134, the west wall of the shrine; this wall seems to have been destroyed at this point (it is shown only in broken lines on the plan, Plate CLXXXI). This stony spread is, according to the absolute levels printed on the plan, about 30 cm. above the top of wall 6134, and is surely one of the "several layers of small rubble stones" which on p. 75 are said to cover the slopes of the earthen rampart, west of the shrine, and to be either an intentional revetment or debris from houses above. In either case, this milk-bowl, and the sixteen other sherds published from the same locus, can scarcely be used as dating evidence for shrine I*A*.

Despite this lack of precision in the analysis of the stratigraphy of the site, this volume is most welcome as providing a yardstick for future work in Palestine. The drawings and the plans are excellent; especially is one grateful for the generous folders on which the plans are printed. The photographs are not so good. Too many of them have been taken in strong sunlight, which produces confusing shadows (for example, Plate VI, No. 6), while illustrations of objects *in situ* are of little use if, as is often the case here, the *situs* is not readily discernible in the picture. Fewer, better, photographs might have helped to reduce the cost of this report.

PETER J. PARR

"ARMS AND THE MAN"

No More War

By Dr. Linus Pauling. Pp. x+254. (London: Victor Gollancz, Ltd., 1958.) 16*s*. net.

The Devil's Repertoire *or* Nuclear Bombing and the Life of Man

By Victor Gollancz. Pp. 192+2 plates. (London: Victor Gollancz, Ltd., 1958.) 10*s*. 6*d*., cloth bound; 5*s*. paper covers.

The Arms Race

A Programme for World Disarmament. By Philip Noel-Baker. Pp. xviii+579. (London: Atlantic Book Publishing Co., Ltd., 1958. Distributed by Stevens and Sons, Ltd.) 25*s*. net.

THESE three books are essentially variants on the thesis that the advent of the nuclear bomb has made the renunciation of war inevitable if mankind, let alone civilization, is to survive. The thesis is stated succinctly by Dr. L. Pauling in his preface, but the level of that preface is scarcely sustained, and even the scientist may find Dr. Pauling's the least satisfactory book of the three. It is indeed addressed to the non-scientist and successive chapters explain in non-technical terms for the general reader the nature of nuclear weapons, what is meant by radioactivity and fall-out, the relations between radiation, heredity and disease. The facts about fall-out are summarized in a separate chapter, which, while not attempting to conceal the incompleteness and contradictions in existing knowledge, strongly supports the recommendation of the Committee on the Biological Effect of Atomic Radiation set up by the U.S. National Academy of Sciences—National Research Council that exposure to radiation should be kept as low as possible. After explaining, in a chapter on the nature of nuclear war, the reasons for his fear that such a war would mean the end of civilization, Dr. Pauling surveys in the following two chapters the several appeals for peace made by scientists and the need for international agreement. Finally, he outlines his own proposal, namely, research for peace.

He suggests that a World Peace Research Organization should be set up within the United Nations to study how to solve great world problems of the kind that have in the past led to war, including an attack on the problem of preventing the outbreak of a nuclear war by design or by accident. Dr. Pauling visualizes such an organization, after a thorough analysis of the problems involved in an international agreement to stop all testing of nuclear weapons, formulating a system offering the maximum safety and the least risk of violation, and he is prepared to place at the disposal of the organization a staff of some 2,000 specialists within two years, a figure which might rise to 10,000 within a decade, and puts the cost of the proposal as initially some 25 million dollars a year and ultimately 100 million dollars. He argues that if world problems were attacked in this way, imaginatively and with original methods by outstandingly able investigators, there are great possibilities of progress and of discoveries which would make the outbreak of a nuclear war far less likely. Except in its scale the proposal is scarcely novel, as the work of the Institute of Pacific Relations has shown for a quarter of a century.

Dr. Pauling is convinced that such an organization would repay its cost in savings in defence budgets and in other ways, and points out that the sum he contemplates is only a small fraction of the military budget of even one country such as the United States or the U.S.S.R. He does not, however, quite meet the point of urgency that is one of the critical aspects of the situation, nor what is implied in the diversion of such a proportion of the world's limited resources in highly varied scientific man-power to this constructive purpose. If the nations were prepared to take that immediate step, may not some more direct action in regard to disarmament be possible now ?

The interest of the book to the scientist lies largely in these last chapters and, while its bibliographical references are rather scanty, it reproduces the Mainau Declaration of Nobel Laureates of July 1955, Schweitzer's declaration of April 1957, and a statement of Einstein's which are convenient for reference. Dr. Pauling does not, of course, ignore the moral aspect, and he argues in conclusion that the use of nuclear weapons is immoral and that morality must now take its proper place in the conduct of world affairs. This, however, is the essence of Mr. Gollancz's book, which presents persuasively, sensitively and with real felicity and sincerity the spiritual and moral issues involved, taking the thesis one step further to argue for unilateral nuclear disarmament. Mr. Gollancz does not shrink from what might be involved in such a step, but no more than Dr. Pauling does he really face some of the real practical difficulties or the moral issue of involving others in the consequences of a unilateral decision.

In this respect, the major contribution comes from Mr. Philip Noel-Baker. Much the longest of the three, his book considers nuclear disarmament as a facet of general disarmament and in the light of the experience gained in the long negotiations for disarmament under the League of Nations. Mr. Noel-Baker is convinced that much of that work is relevant to present problems, and without disguising the need for anxiety and urgent action he takes a hopeful view of the possibilities. The scientist will find much of interest in this lucid, well-documented and authoritative survey; not least, a compelling demonstration of the futility of military or defence research. The argument is realistic, without ignoring or despising the moral argument, and although it does no more than outline the broad stages by which disarmament should proceed, it calls just as incisively as Dr. Pauling for bold and large steps, including the abolition of military research, and for the patient and determined pursuit over many years of new policies and reforms based on known facts, which the recently established Institute of Strategic Studies could well help to disseminate. R. Brightman

MODERN MIND

The Emergence of the Modern Mind

Edited by Prof. Frederick C. Gruber. (The Martin G. Brumbaugh Lectures in Education.) Pp. 93. (Philadelphia: University of Pennsylvania Press; London: Oxford University Press, 1958.) 20*s.* net.

THIS book consists of the four Martin G. Brumbaugh lectures given at the University of Pennsylvania in 1957. They are popular lectures, designed mainly for students of education. Prof. Conway Zirkle, writing on "Our Biological Inheritance", paints a lively but gloomy picture of man as the most successful of animals, yet ill-adapted to the cultures he has produced; knowledge has grown too big for us, our work is dull, civilization is a strain from which the human animal sometimes seeks violent escape; perhaps hope is possible when we look back in history and see what catastrophes we have survived or consider what further successful adaptations we may achieve in the next half million years; we may even survive some of our present world-views. Prof. Edel, on "The Greek Image in American Thought", emphasizes the freshness of Greek thought for Western civilization and our need to look back to the Greeks for new ideas. He is scornful of those bolstering up reactionary philosophies by skilful quotation from Plato. The Greeks must be approached in their own spirit of free inquiry; the questions they discussed are the ones we find important; as an example Edel gives a skilful analysis of the underlying assumptions of democracy, looked at in the light of Plato's "Republic".

The other two lectures are less interesting. Prof. Ethel Alpenfels's essay on "The Mind and the Mores", is very slight; she applies the social anthropologist's view of culture to American 'folkways and mores'; but she never makes it clear how far human beings are 'determined' by their cultures and how far they are free individuals capable of independent thought. Prof. Percy Miller's picture of "Nineteenth Century New England and its Descendants" would be of more interest to Americans than to Britons; his references are too off-hand for us to judge the relevance of his criticisms; and although he wants to show us the greatness of Henry Thoreau, he does not tell us enough about his life, work and writings to convince.

It will be noticed that the link between these essays and the title of the book is tenuous, but this is not important. Although there is nothing original in these lectures and the writing is sometimes pretentious or naïve, they are on important topics and would have a stimulating effect if used, for example, in the sixth forms of grammar schools as a basis for discussion. T. H. B. Hollins

NEUROPHYSIOLOGY OF BEHAVIOUR

Ciba Foundation Symposium on the Neurological Basis of Behaviour

Edited by G. E. W. Wolstenholme and Cecilia M. O'Connor. (In commemoration of Sir Charles Sherrington, O.M., G.B.E., F.R.S., 1857–1952.) Pp. xii+400. (London: J. and A. Churchill, Ltd., 1958.) 52*s*. 6*d*. net.

THIS volume contains a collection of some nineteen papers presented at a Ciba symposium commemorating the birth of Sir Charles Sherrington in 1857. As is usual with Ciba symposia, the meeting was attended by only a small international group, and the book is intended to present the proceedings to a much wider circle. The papers covered many fields related to neurology, but the main emphasis was, as might be expected, on neurophysiology and experimental neurology.

The latest data on the activity of single neurones of the spinal cord are reviewed by Eccles, while the behavioural effects of lesions (Bard, Brierley, Kluver) and electrical stimulation, both in animals (Olds, Andersson, Monnier) and in man (Penfield) are very adequately covered. Other fields discussed are: sexual behaviour (Harris), the effects of stress (C. P. Richter), the rhinencephalon (Green), brain enzymes (Rosenzweig) and drug action (Elkes). Many of the papers are reviews containing material much of which has already been published; nevertheless they serve to bring this together for discussion, which follows each paper. On the other hand certain papers contain a proportion of new information, and these, while they illustrate trends in research, also focus attention on the fact that new developments in this field must depend upon advances in technique. For example, Olds outlines the new results which are coming from experiments on electrical self-stimulation in animals; Jasper reviews the responses of single cortical neurones in unanæsthetized animals during conditioning; and Malcolm discusses the activity of cortical neurones in freely moving animals. All these developments and many others which are providing information linking electrophysiological and behavioural studies depend upon new technical skills.

The only criticism which one might make is that the contributions made by psychology and biochemistry to this symposium are small, yet both these fields of study are becoming increasingly important to work on neurological mechanisms. However, no symposium can ever be truly comprehensive if it is to be confined to a single volume at a reasonable price, and this book provides an excellent review of our present state of knowledge in this subject. It is well illustrated and contains an adequate index.

P. B. BRADLEY

PHYSIOLOGY OF THE CEREBELLUM

The Physiology and Pathology of the Cerebellum

By Prof. Robert Stone Dow and Prof. Giuseppe Moruzzi. Pp. xv+675. (Minneapolis, Minn.: University of Minnesota Press; London: Oxford University Press, 1958.) 100*s*. net.

STUDENTS of cerebellar physiology have been well served by a sequence of splendid critical writings, each marking a distinct advance in knowledge, and in some degree defining the direction of later research. Foremost among them stand those of Sherrington (1900), Luciani (1915), Bremer (1935) and Holmes (1939). Dow and Moruzzi's new book will take its place with these. A physiological and pathological study of the cerebellum, it is planned as companion to a forthcoming morphological treatise by Larsell.

In their general nature, and in the technical approach to them, cerebellar problems resemble those presented by other parts of the central nervous system, but without preoccupation with the relation between nervous and mental events. The oldest approach tries to analyse the disorder of function—in this case, of posture and movement—resulting from destruction of the cerebellum or of some part or parts of it. Following the injury, the pattern of disability undergoes progressive change until a final steady state is reached. It is difficult to determine how far the disability at each stage is 'negative', due to lack of cerebellum, and how far 'positive', due to new activity of surviving nervous tissue. The general conclusion, however, is that the cerebellum tends to subdue postural reflexes on one hand, and on the other, to reinforce and steady the motor outflow from the brain. Electrical stimulation, although its effect is mixed, confirms the reality of these two streams of action.

The large and richly folded cerebellar cortex (with an area only a small fraction of which is exposed on the surface of the organ) receives impulses from all the receptors, and not only from the proprioceptors, as would have been expected from pioneer work. These impulses arrive at areas the surface localization of which is sharpest in deep anæsthesia. The cortical Purkinje cells send impulses to the cerebellar nuclei and thence to brain and cord. How far is this cortical output directly driven by the afferent input, and how far by intrinsic neuronal activity of the cortex? This cortex has the same apparently homogeneous, but very complex, microscopical structure throughout its extent. In the past there has been some loose usage of the term 'functional localization'. Anatomical localization of areas of arrival and departure of impulses has been abundantly shown. Is the active response of the cerebellar cortex to incoming impulses also localized, or is there, rather, spread and mass action, converging ultimately upon the different corticofugal systems?

On these and many other questions, this book assembles a wealth of experimental and clinical fact. The bibliography has about 2,000 references, old as well as new, and in many languages. These are not merely quoted, but critically appraised: the authors have taken great trouble to extract from them the facts needed for reasoning, and to reject poor observations (for example, those with inadequate anatomical control). The arrangement is methodological: ablation experiments; stimulation experiments; electrophysiological experiments; the cerebellum and other central structures; clinical symptoms; pathology. The analysis of clinical symptoms reveals the full stature of Gordon Holmes's contribution to cerebellar physiology. The pathological processes affecting the cerebellum are admirably described from the physician's point of view. Some of the sections end with interesting general essays, and these, and the essay "General Considerations on the Function of the Cerebellum", might well be read consecutively. The book as a whole would probably not be read consecutively by anyone other than a reviewer; but it is all very readable, well indexed and well supplied with cross-references. Its great virtue is that it proclaims the important matters on which we are ignorant, and does not somehow convey the idea, as other writers on the nervous system, no doubt unintentionally, have sometimes done, that our understanding is all but complete. By this frankness it hopes, and is likely, to stimulate research. It is the fruit of more than twenty years practical work, thought and reading by both authors. It could not possibly be mistaken for a mere journalistic compilation. C. G. Phillips

CLINICAL AND EXPERIMENTAL CANCER RESEARCH

Carcinoma of the Lung

Edited by J. R. Bignall. (Monographs on Neoplastic Disease at Various Sites, Vol. 1.) Pp. xii+298. (Edinburgh and London: E. and S. Livingstone, Ltd., 1958.) 55*s*. net.

Variables Related to Human Breast Cancer

By A. Elving Anderson, Harold O. Goodman and Sheldon C. Reed. (A Study from the Dight Institute of Human Genetics.) Pp. xiii+172. (Minneapolis, Minn.: University of Minnesota Press; London: Oxford University Press, 1958.) 32*s*. net.

Proceedings of the Second International Symposium on Mammary Cancer

Held at the University of Perugia, 24th to 29th July, 1957. Edited by Lucio Severi. Pp. liv+871. (Perugia: Division of Cancer Research, 1958.) 12,000 lire; 145*s*.; 20 dollars.

THREE recent books illustrate a current trend towards the detailed study of neoplasia in particular organs or tissues in human beings as well as in animals. Carcinoma of the lung is the subject of the first of a series of monographs designed to cover the range of neoplastic disease in special sites. The series is based primarily on the first-hand clinical experience of a group of postgraduate teaching hospitals in London supplemented by expert aid from other sources. The present volume, reflecting the practice of the Royal Marsden and Brompton Hospitals, includes a discussion of etiology, occupying about one quarter of the whole, by R. Doll. Dr. Doll expounds his views on the etiological importance of cigarette-smoking lucidly and persuasively. The weakest link in the argument seems to be the identification of the mechanism of carcinogenesis; the evidence for decisive operation of carcinogenic hydrocarbons is unconvincing. The main thesis rests on information about what actually happens in human beings, and although Dr. Doll is convinced by the evidence incriminating cigarette-smoking, he recognizes that inconsistencies persist and that interpretation is difficult.

The intrinsic hazards in the study of the etiology of human neoplasia are well shown in a report from Minnesota of a careful and critical investigation of the role of genetic factors in cancer of the human breast. The authors give especial attention to the validity of research methods; many previous investigations are clearly inadequate. Their own conclusions are cautious. They find good evidence that mothers, sisters and daughters of breast-cancer patients are about twice as liable to cancer of the breast as other women of similar age, and that the enhanced liability does not apply to cancer at other sites. Genetic factors are probably involved in the etiology of human breast cancer but are less important than non-genetic factors. These investigators are not satisfied that information now available about such factors as marital status, number of pregnancies and breast-feeding is sufficient to justify the advocacy of prophylactic measures, and they show a welcome recognition of the danger of meddling with the lives of human beings on the basis of imperfect and incomplete understanding of neoplastic processes in the breast.

The limitations of knowledge are also evident in the report of the Second International Symposium on Mammary Cancer held in Perugia in 1957. More than eighty contributions from fifteen countries cover a wide range of observations and opinions, human and animal studies being about equally represented. The endocrine aspects of mammary cancer receive most attention. Although there is wide agreement among the contributors that hormones are important in the etiology of cancer of the human breast, the mechanism of their action is not known. Moreover, the endocrine management of advanced breast cancer remains almost wholly empirical. These matters call for the closer integration of clinical and experimental research which this valuable symposium was designed to encourage; the clinical and experimental approaches are complementary and not alternative or competitive. The report scarcely does justice to the value of a symposium that brought clinical and laboratory workers together for informal discussions as well as formal expositions, but it is welcome, nevertheless, as a record of current thought and research on mammary neoplasia. All three books may be commended as valuable contributions in their several ways to the study of a subject of great complexity. L. Foulds

MECHANISM OR VITALISM?

The Physical Foundation of Biology

An Analytical Study. By Prof. Walter M. Elsasser. Pp. x+219. (London and New York: Pergamon Press, 1958.) 30*s*. net.

THE conflict between mechanistic and vitalistic philosophies has never quite subsided. Biologists, who on the whole have a profound respect for the senior physical sciences, tend to hold mechanistic views, at least as a working hypothesis, while physicists, knowing rather more of the limitations of their own discipline, are more inclined to assign special properties to living organisms. Prof. W. M. Elsasser, whose professional domain is magneto-hydrodynamics, has taken great pains to survey those phenomena displayed by living creatures which can be described in mechanistic terms, so as to identify the residue of functions which, he asserts, cannot be effected by physical means. For phenomena in this class, which cannot be interpreted in terms of pure mechanism, he proposes the term 'biotonic', which he defines as "Any causal relationship which involves an increase of information content in the system with the passage of time". The most prominent member of this class, he suggests, is organic growth of information, and he tries to show that neither genetic nor cerebral information can conceivably be "stored" in a physical sense, because of the minute scale of the structures involved—the chromosomes of the gametes or the nerve tissue of the brain. In an artificial computing machine there may be several grades of storage register, giving different degrees of capacity, accessibility and permanence, each fulfilling particular functions, and exploiting various physical effects such as ultrasonic vibration, electrostatic induction, and magnetic induction, apart from the familiar records in printed or punched cards. The total information storage capacity of a large computer may be quite imposing but does not approach the order of information contained in a human organism which, Elsasser suggests, may be as high as a thousand million bits. If a storage register of this capacity were required, the physical size of the storage system would have to be reduced, and a point would be reached at which the random variations of the system, the Brownian movement, or noise-level, would be of the same order as the magnitude of the stored signals. In such conditions, so the argument runs, the inevitable loss of information or ambiguity can be made good only by redundancy in the form of repetition or reduplication, which requires still more storage space, and so on. The conclusion reached is that no mechanical storage system can be imagined, still less constructed, which would contain enough information to specify the development or the mentality of a human organism. In the special case of human memory a particular difficulty, according to Elsasser, is that "There is no anatomical evidence for a storage organ", and also, "brain physiology has not brought to light any evidence for . . . special scanning devices" which, according to engineering principles, are needed for the selection and distribution of large stores of information.

Thus, proceeding from the Bergsonian idea that "the deviation of organisms from mechanistic behaviour ought to be studied in terms of the failure of information storage", this eminent and scholarly physicist develops a logical and consistent argument in support of the notion of epigenesis, claiming that the existence of biotonic laws is justified by the principle of finite classes which prohibits logical decisions involving operations in immense classes.

The argument is not easy to follow, and the reader's confidence is strained by the intrusion of several errors and oversights, particularly in the sections on neurophysiological data; neither the velocities nor the durations of nerve impulses are limited to the ranges quoted, and their strict relation to impulse wave-length should have directed the author's attention to the logical inconsistency in this paragraph. There is in fact some evidence of a scanning or space-time transforming mechanism within the brain, as well as of considerable redundancy in both genetic and cerebral structures. Not all matings are fertile, and many have monstrous issue ; by no means all memories are true, many are redundant and all are fragile.

In spite of the author's reasonable doubts, the storage capacity of a statistically assembled system of ten thousand million elements is not easy to estimate, and it may well be that in free permutative combination the figure would be of the required order. The same consideration applies to the inter-connexion of radicals in the nucleo-protein systems of chromosomes ; our present lack of complete factual knowledge does not seem to justify a philosophical denial of the possibility.

In a book of this size and scope, a subject index would have helped to restore biotonic energy, but there is an excellent summary in a few pages.

W. Grey Walter

BIOLOGICAL ULTRASTRUCTURE

Biological Ultrastructure

By Arne Engström and J. B. Finean. Pp. ix + 326. (New York : Academic Press, Inc., 1958.) 8 dollars.

The appearance of a new book in this rapidly developing field is greatly to be welcomed. During the past ten or so years an extraordinarily high degree of success has attended the application of various biophysical techniques and ideas to the study of molecular biology, and the time is certainly ripe for these developments to be recounted in generally accessible form. In the work under review, Prof. Engström and Dr. Finean have gone a considerable way towards doing this. The book commences with a section on "Methods in Ultrastructural Research", followed by an admirable account of "Principles of Molecular Structure", and succeeding sections consider the role of proteins, lipids, carbohydrates, nucleic acids and mineral salts in biological systems, in each case working up from simple molecules to the complex structures which they form in living material. This is an ambitious project, and in a book of this size, much can be treated only in general outline. Nevertheless the work will provide a useful introduction to the field for students, and others, particularly if used in conjunction with the earlier monograph by Frey-Wyssling, where greater emphasis is placed on cell structure. There are, however, a number of points in the book where one feels that considerable opportunities for arousing interest and enthusiasm have been missed, and where the summaries of recent developments seem lacking in colour and emphasis.

The section on the preparation of specimens for the electron microscope may leave the newcomer unaware of the dominating and almost unbelievably successful part played by studies on sectioned material in contemporary work, despite the technical details which are given of the methods used. The section on X-ray diffraction contains no mention of the fact that helical structures give a specific type of diffraction pattern ; and the omission of any account of hydrodynamic, light-scattering and optical rotation techniques could be criticized.

The section on proteins contains a great deal of useful information attractively presented, but in the treatment of chain configurations, the key part played by the recognition that the X-ray diffraction pattern given by synthetic α-polypeptides was that of a non-integral helix, which could be computed elegantly and in detail, and which agreed closely with that given by the Pauling–Corey α-helix, is slurred over ; and as a result one is left with an impression of vagueness which does less than justice to the evidence. Greater emphasis might also have been given to the importance of the successful application of the heavy-atom technique in X-ray diffraction studies of crystalline proteins.

Muscle and nerve are well covered (although a more extensive discussion of unmyelinated fibres would have been welcome) and the section on lipids is excellent. The section on nucleic acids is rather short in view of the elegance and interest of much recent work in this field. The genetic implications of the specific pairing of the bases required by the Crick–Watson double-helix structure for deoxyribonucleic acid are, surprisingly, not mentioned at all, and the recent work on tobacco mosaic virus, a superb example of the success, interest and importance of careful and detailed X-ray diffraction studies, is summarized only very briefly, and incorrectly; there is no mention of X-ray work on spherical viruses. On the other hand, the section on the role of mineral salts is extremely interesting and informative.

The principle of giving references, in general, only to key works containing more complete bibliographies has some advantages, but may sometimes leave the reader in the position of having come across tantalizing pieces of information which he can follow up, or the authority of which he can check, only by a prolonged search through the literature.

Despite these criticisms, the book remains a most useful introduction to the subject, and the authors are to be congratulated for their labours in bringing together so much information into one convenient volume. H. E. HUXLEY

CLASSIFICATION OF THE DIGENETIC TREMATODES

Systema Helminthum

By Prof. Satyu Yamaguti. Vol. 1: The Digenetic Trematodes of Vertebrates. Part 1: Pp. xi+1–980. Part 2: Pp. iii+981–1575. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1958.) 90 dollars; £34 the two parts.

SATYU YAMAGUTI has spent nearly thirty years on the production of his "Systema Helminthum", the first volume of which has now appeared. His work therefore commands the highest respect. Essentially, the book is a compilation of diagnoses of 102 families, 355 sub-families and 1,024 genera of digenetic trematodes, followed by a list of 4,037 references to the original literature, 1,302 illustrations grouped in 106 plates, and an index of the names of taxonomic units and their authors taking up rather more than 130 pages of two columns each. For the assembly of this tremendous fund of information Yamaguti merits high commendation. The diagnostic data are presented in Part 1 under the headings of definitive hosts—fishes, amphibians, reptiles, birds and mammals—which is a useful arrangement so long as it is realized that related species, and even one and the same species, may utilize more than one class of host. The entire taxonomic scheme is set out in Part 2 as an alphabetical list of families, sub-families and genera, whereas the arrangement in Part 1 is neither alphabetical nor the order in which groups may be separated by means of the keys provided. It is disconcerting to the reader to find this apparent disarray; he is prompted to ask why, for example, the relative order of the important families Plagiorchiidae, Lecithodendriidae, Microphallidae, Opisthorchiidae and Paramphistomidae should be 12345 for reptiles but 41325 for fishes, 52431 for amphibians, 14325 for birds, and 12435 for mammals. An alphabetical list has the virtue of ease of reference, even if it does leave unconsidered important questions of affinities.

The classification of the Digenea has generally been on the basis of comparative morphology of the adults, but G. R. La Rue (*Exp. Parasitology*, 6, 306; 1957) has revived the method of utilizing developmental data. His scheme recognizes super-orders, orders, sub-orders, super-families and families and is based particularly on the development of the excretory vesicle and associated parts. Many helminthologists will hesitate to accept it, on the grounds that both larval and adult characters are necessary for the delineation of genetic relationships. As Yamaguti has dealt mainly with adult characters, we can scarcely expect his scheme to provide more than just a list of families. What is striking is the great inequalities of families in this scheme; 13 of the 102 families comprise 10–25 sub-families and 21–106 genera each, making totals of 201 out of 355 sub-families and 551 out of 1,024 genera. At the other extreme, 59 families contain no more than four genera each; 31 of them contain one genus only, 13 contain two genera, 9 three genera and 6 four genera. This aggregate of families comprises only 108 genera and only 30 sub-families are represented. The 30 families yet to be considered have more than four genera and fewer than 10 sub-families each, and we may presume that they comprise 365 genera and 124 sub-families, 16 of the latter with only one genus.

The distribution of Digenea in the classes of host is also unequal; 54 families are represented in fishes, 13 in amphibians, 28 in reptiles, 29 in birds and 36 in mammals. The total exceeds 102 because 58 families are represented in two or more classes of host; the actual number of overlaps is 91, of which 15 involve fishes, 13 amphibians, 21 reptiles, 21 birds and 21 mammals, and the actual number of families involved is 33. Of the families containing one genus only, only the Orchipedidae occurs in more than one class of hosts (birds and mammals); of the remainder, 16 are represented in fishes, 0 in amphibians, 3 in reptiles, 3 in birds and 8 in mammals. The total numbers of families represented in one class of host only are 39 in fishes, 0 in amphibians, 7 in reptiles, 8 in birds and 15 in mammals. Families restricted to two or three classes of hosts number 1 in fishes and amphibians, 3 in fishes and reptiles, 3 in amphibians and reptiles, 1 in reptiles and mammals, and 11 in birds and mammals, and also 4 in fishes, amphibians and reptiles, 1 in fishes, reptiles and birds, and 3 in reptiles, birds and mammals. One family, the Echinostomatidae, is represented in four classes of hosts (fishes, reptiles, birds and mammals), and 5 families are represented in all five classes, namely, the Lecithodendriidae, Opisthorchiidae, Paramphistomidae, Plagiorchiidae and Microphallidae.

A work of this sort could scarcely be free from blemishes of one sort or another. There are many simple misspellings. Fig. 752 (Plate 62) and 1126 (Plate 93) are mislabelled *Pseudopsilotrema*, a name which does not appear in the index, and the names *Saccocoelium* and *Diphterostomum* are misspelt in various places. Many special citations made in the text are not supported by references in the list. For example, the reader's appetite is whetted on p. 184 concerning certain developmental features, a reference is cited and he is invited to see p. 371, where more recent information is given briefly in a second citation; he is then chagrined to find that the second reference is not supplied. Much more serious is the omission of any data concerning the sizes of trematodes and their organs and parts. No pretence is made of dealing with species beyond listing their names and, admittedly, ranges of size are difficult to specify for genera. However, genotypes are specified, and space would have been made available for size data had generic diagnoses been pruned of many redundant expressions which occur in them. Otherwise, some indication of size should have been given with the figures. The terms used in the text to denote size are useless because undefined. One solitary figure (7, Plate 1) has a scale; 1,301 figures leave the reader baffled regarding size. The figures of *Heterophyes heterophyes* and *Fasciolopsis buski* are about 55 mm. and 52 mm. long, respectively, whereas actual lengths may be 2 mm. and 75 mm. A reader having no foreknowledge of actual differences in size between trematodes may be greatly deceived by the figures, some of which are excellent but others are very poor and too small to be serviceable. He will also be disappointed in the general account of the digenetic trematodes, which barely covers one page and might have been amplified to an interesting and useful statement.

In spite of its shortcomings, the work will be much appreciated by all those who are concerned with trematodes, and its publication is at the same time a remarkable achievement and a notable event. The book summarizes most of the laborious and tedious systematic work which has been carried out, but it does indicate to the enlightened initiate how much research of a synthetic nature remains to be done. BEN DAWES

HARMONIOUS HERPETOLOGY

A Field Guide to Reptiles and Amphibians of the United States and Canada East of the 100th Meridian

By Roger Conant. (The Peterson Field Guide Series.) Pp. xv+366+40 plates. (Boston, Mass.: Houghton Mifflin Company, 1958.) 3.95 dollars.

DESPITE the number of books that already exist on North American herpetology, until now there has been no up-to-date survey and guide to the reptiles as well as the amphibians of that continent. For many years the little book of Schmidt and Davis provided an accurate guide to the snakes, but with the changes that have taken place in the nomenclature and taxonomy of American herpetology there became an urgent need to revise the "Field Book of Snakes" or replace it with another guide. In 1957, there appeared the "Handbook of Snakes" by Wright and Wright, but in two bulky volumes it could scarcely be considered a substitute for the earlier field guide. The book produced by Roger and Isabelle Conant is the answer to the urgent demand; it is remarkable in that it covers not only the snakes but also all the reptiles and amphibians that are known to occur in North America east of the 100th meridian and yet is of a handy pocket size and is reasonably priced.

The tradition of the Peterson Field Guide Series of combining scientific accuracy with readability has been maintained in this latest volume. In Britain many people are familiar with the "Field Guide to the Birds of Britain and Europe", by Peterson, Mountfort and Hollom, and some may be acquainted with the companion volumes on American birds; all praise the success and outstanding merit of these guides. The field guide to reptiles and amphibians of eastern North America, however, contains several special virtues. The inclusion of distribution maps in the guide to the British birds was at that time an unusual feature, but their value was at once acknowledged and the habit of including maps in check lists and field guides spread to other works. The Conants' book provides a series of well-executed maps which are confined to the end of the book and on which are shown the range of each species and subspecies discussed in the text, so that a check list for any region, state or county can easily be compiled. The photographs are of a superb quality and Mrs. Conant is to be congratulated on the excellent results of her painstaking task of hand dyeing more than 400 of them. Many of the original illustrations were seen by the reviewer, when it was evident that Mrs. Conant had spared no effort in achieving accuracy in colour and detail. Only live animals were photographed. A little of the brilliance of a few of the original illustrations has been lost in reproduction yet no one can deny that for identification purposes the best photographs and colour plates of American reptiles and amphibians are to be found in this book.

The format is essentially the same as in the other guides in the series. Specimens can be identified from the illustrations, with the aid of the salient features of the species listed on the facing page, or from the text where under each species are guides to the identification with notes on voice (in the case of the frogs and toads), size, similarity with other species, and range. Habitat notes and information on habits and natural food are given where known.

The introduction, and the chapters on the techniques employed in collecting reptiles and amphibians, on transporting the specimens, on snake-bite and its treatment, and on the care of the animals in captivity are highly commendable. Although most people will agree on the clumsiness of the term "reptiles and amphibians" when it occurs several times on one page, some purists will be disturbed to find it abbreviated to "herptiles" in this book. Nevertheless, Roger Conant's style is refreshing in its simplicity, and the expressiveness of his descriptions of the mating calls of frogs is worthy of special praise. The voice of the western chorus frog, *Pseudacris t. triseriata*, is likened to the sound produced by "running a finger over approximately the last twenty of the small teeth of a good-quality pocket comb, rubbing the shortest teeth last". Other mnemonics for frog calls range from "loose banjo strings" to "high pitched riveting machines".

"A Field Guide to Reptiles and Amphibians of the United States and Canada East of the 100th Meridian" is an essential companion to the collector of American "herptiles", to those whose interests are in the realms of systematics and behaviour and who require a dependable guide to the identification of the American species and also to the beginner in herpetology.

Mr. Conant has achieved success with his field guide to the eastern species. It is hoped that he will be persuaded to tackle with the same courage and patience a field guide to the herpetofauna of western North America. A. G. C. GRANDISON

THE ART OF GRAFTING

The Grafter's Handbook

By R. J. Garner. Revised edition. Pp. 260+32 plates. (London: Faber and Faber, Ltd., 1958.) 25*s*. net.

DURING the eleven years that have elapsed since the publication of the first edition of "The Grafter's Handbook" there has been ample proof of its value not only as a long-awaited text-book for the student, but also as a reference book for the practical horticulturist and nurseryman.

There can be little doubt that this revised and enlarged edition will receive an even more enthusiastic welcome, for it covers in detail all known methods of grafting. For those who wish to study seriously the theory and practice of this most fascinating of the gardening arts there is a full description of the methods, their advantages and uses. The author is to be congratulated on the way he has combined the results of his long experience as a practical propagator with the findings of modern research, in which he himself has played an important part at the East Malling Research Station.

A review of this book would not be complete without a word of praise for the publishers and their associates. They have produced a book of high quality, attractively bound and with the pages opening flat, at a modest price.

Prior to the opening chapter, which is devoted to information on the subject of natural grafting and its bearing on artificial methods, there is a glossary of terms used. There are also notes on the reasons for grafting, all of which are of value and interest, particularly to the student.

In Chapter 2 the author discusses compatibility and cambium contact, and the reader is left in no doubt regarding their importance. The following chapters deal with the role of rootstocks and their propagation. There is also excellent information on the collection and treatment of the wood or growths to be used as scions and, to emphasize the importance of the various points, each is dealt with under a separate heading.

Chapter 5 is devoted to "Tools and Accessories", and here the author covers very fully the various knives and other small tools required for the many methods of grafting that he describes. There are also useful notes on the various commodities that are necessary for the completion of the work. This is information that is so often neglected in many books dealing with the practical aspect, while for the student it provides information that is difficult to obtain.

Chapter 6 deals with the many methods of grafting, divided into two main divisions, namely, approach grafting and detached scion grafting. The reader is introduced to each method with clear and concise notes that are supported by excellent line drawings by the author and, in some instances, photographs as well. The way in which this important part of the subject is covered can be judged from the fact that some eighty pages are devoted to this chapter—nearly one-third of the book.

There is much useful information in Chapter 7, which deals with tree-raising in nurseries, and the methods adopted for grafting under glass and in the open are described and commented on. In the next chapter, Mr. Garner deals fully with the methods of grafting used to rejuvenate old trees and to change varieties. There is also information and some excellent illustrations of the methods of grafting employed to repair and save trees that have their bark girdled by animals or damaged in other ways.

The author concludes with a chapter which deals with the misuse of grafting and the interaction of stock and scion. Also discussed are those interesting if not very useful bigeneric trees known as graft-hybrids or chimeras in which an intermixture of tissues occurs to provide in growth a mixture of both genera, as, for example, *Mespilus* and *Crataegus* in *Crataegomespilus*.

A well-prepared index is provided and completes a book that should find a place on the bookshelf of all gardeners and nurserymen, as well as that of the keen amateur.

S. A. Pearce

UPPER DEVONIAN SPIRIFERS OF THE CATSKILL DELTA

"Spirifer disjunctus"

Its Evolution and Paleoecology in the Catskill Delta. By Hugo Greiner. (Peabody Museum of Natural History, Yale University, Bulletin No. 11.) Pp. iv+75+13 plates. (New Haven, Conn.: Peabody Museum of Natural History, Yale University, 1957.) n.p.

From a study of numerous specimens of Upper Devonian spirifers (Brachiopoda) from the Catskill delta of New York State, the author claims that what were formerly considered to be varieties of a single species actually constitute a tribe of genetically related species of *Cyrtospirifer*, each having a limited stratigraphic range and belonging to two principal phyletic lines.

The specimens were obtained from littoral or sublittoral beds, mainly sandstones and shales, 2,500 ft. thick, accumulated during 5–6 million years, and ranging from the base of the Chemung to the base of the Mississippian.

Hemmed in by a shore line to the east and by deeper water deposits to the west, the Catskill delta in Devonian times supported some 1,178 species, only a small number of which were near-shore dwellers like *Cyrtospirifer*. The shifting of the delta westwards resulted in sudden changes of facies and the necessity for adaptation of the tribe to various environmental niches.

Six species occur predominantly in sandstone, nine species in shale and three species are found in both shale and sandstone. Most of the species have short ranges, but two showed great adaptability to changing environment and cut across formational boundaries with no marked morphological change, both giving rise to a number of species. The ancestor of the tribe is not known; some species seem to have originated locally while others are migrants from another region, and hybrids are recognized. Early in the evolution of the group there was a considerable number of species probably associated with a narrow sublittoral zone. A broader platform with fewer ecological niches tended to produce fewer species in the later history of the region.

Attenuate forms appear earliest, but alate forms tend to occur in shaly facies and more quadrate forms in a sandy facies, though this is not consistent. Auriculation or mucronation would keep shells on the surface of the mud and prevent currents from upsetting them. The largest shells appeared relatively late.

Lateral costae number about 50 in some early forms, but later forms have about 24 broader costae, while bifurcation of costae within the sinus tends to decrease in the later species.

Small size of adductor scars are said to be indicative of weak muscles which would be suited to quiet muddy sea-floor conditions, while large adductors, coarse costae and thickened ventral umbones distinguish specimens which lived in sandy wave-swept places. The angle of divergence and length of the dental lamellae seem to be variable characters.

As a palæoecological and evolutionary study the paper is of considerable interest, but the identification of the eighteen species (thirteen of them new), some with overlapping ranges and with considerable variation in shell outline, is likely to cause trouble for the taxonomist. No statistical study of the species was attempted.

The paper is well presented, except for a number of misprints, and is illustrated by thirteen plates of excellent photographs.

It is regretted that the author could not have made a rapid survey of European species of *Cyrtospirifer*, and especially *C. verneuili* (Murchison), the type species from the Upper Devonian, Frasnian of Ferques, Boulonnais, which closely resembles some of the Catskill species in form, ornament and spinose micro-ornament. The retention of the name *Spirifer disjunctus* J. de C. Sowerby for the tribe is unfortunate, since this species is doubtfully synonymous with *C. verneuili*, and has actually been assigned to a separate subgenus. H. M. Muir-Wood

NAMES AND CIPHERS IN ORGANIC CHEMISTRY

Nomenclature of Organic Chemistry, 1957

(International Union of Pure and Applied Chemistry.) Pp. v+92. (London: Butterworths Scientific Publications, 1958.) 15*s*.

A Proposed International Chemical Notation

Prepared by the Commission on Codification, Ciphering, and Punched Card Techniques of the International Union of Pure and Applied Chemistry. Tentative version subject to revision. Pp. vii+165. (London: Longmans, Green and Co., Ltd., 1958.) 35*s*.

The already embarrassing problems of nomenclature are intensifying through the rapid acceleration of discovery in organic chemistry, resulting in the preparation of more and more complex synthetic compounds and the elucidation of the structures of natural products, often exceedingly complex. The discoverers of necessity invent trivial names, but these convey nothing to the uninitiated. The ideal name for a compound is one which will immediately tell a chemist its structure, enabling him to write down a formula or construct a molecular model. It should also be internationally acceptable, printable and suitable for indexing. There is a natural tendency for a group of workers in a new field to invent a special nomenclature in that field which may or may not be compatible with that in other fields—the steroid field is an example. A vested interest is thus created, and the unfortunate people charged with the task of standardizing meet a dilemma. Editors can do something to discourage this growth of rogue nomenclature by giving advice to authors, as they frequently do, but they may be too late.

In the two books under review we have an opportunity of comparing two entirely different systems of recording and communicating the constitution of any organic compound. The first book accomplishes a great task in revising and standardizing conventional nomenclature in limited fields; the second throws convention to the winds and makes an entirely fresh start, using little that is familiar except the initials of most of the elements.

Serious attempts to obtain international agreement on organic nomenclature date from the Geneva meeting of 1892. The next important development was in 1930, when the Liège rules were drawn up by the Commission of the International Union of Chemistry. A major revision of these rules is now being undertaken, sponsored by the International Union of Pure and Applied Chemistry and in the first book under review we see the first results of this important work. The definitive rules now recommended concern the naming of hydrocarbons of all classes, of heterocyclic systems and of steroids; that is to say, they are concerned with molecular frameworks without substituents, but including derived radicals. Hydrocarbons are divided into classes, aliphatic, monocyclic, fused polycyclic, bridged, spiro and ring assemblies, with a special group for terpenes. In the last group, many trivial names are admitted, with some changes, camphane, for example, becoming bornane. A large list of trivial names is also approved for hydrocarbons of the fused aromatic type, including such newcomers as coronene and ovalene (but not zephrene, I notice). The form biphenyl is adopted for the hydrocarbon which has always been called diphenyl in Great Britain. The systematic naming and numbering of cyclic hydrocarbons of all kinds and of heterocyclic systems follow the conventions of Patterson and Capell's 'Ring Index', so far as I could tell after a careful comparison. In addition, the useful *a* method of naming heterocyclic fused ring systems as aza, oxa, thia derivatives of a homocyclic parent is given as an alternative to the fusion system. In the field of steroids the Commission has bowed to established custom and accepted the numbering of the cyclopentaphenanthrene system, which flouts all the rules. To simplify nomenclature in this field the use of a number of trivial names is proposed, starting with 5α- and 5β-gonane for the two important stereochemical isomers of perhydrocyclopentaphenanthrene. The volume concludes with some tentative suggestions for nomenclature in the vitamin B_{12} field. The typographical conventions and spellings used in this book are those of *Chemical Abstracts*, which differ appreciably from British usage and the hope is expressed that each nation will attempt to reduce such variations as exist in their publications. In this connexion, the Chemical Society (London) has just announced its intention of making certain changes which will, incidentally, bring its usage more into conformity with American practice. In this review these changes have been adopted.

The ingenious system of ciphering developed in the second book under review is obviously the outcome of careful study. It is based on ideas put forward in 1946 by Dr. G. M. Dyson. Other people at about the same time and later were thinking along similar lines and some of their ideas have been incorporated in the final draft, though essentially it is the Dyson system. The aim is to give an unambiguous cipher to any structure without using any names, trivial or other. This would cut out linguistic difficulties and avoid the strain of having to memorize a multitude of trivial names.

A cipher is composed of letters, figures and punctuation signs. The basic idea is that any structure is made up of chains, rings and functional groups which can be represented by simple signs. A chain of n carbon atoms can be represented by C_n; a saturated ring of n carbons by An; a ring of n carbons having the maximum number of non-cumulative double bounds by Bn; all free valencies are considered to be saturated, so H need not be ciphered except in special cases. The system of numbering enables junctions, fusions and substituents to be accurately ciphered and it is to be noted that Dyson numbering of familiar rings differs greatly from conventional numbering. It is impossible here to go further into detail but a few examples may be given. Thus, C_4 is *n*-butane; C_4.C,2 is isopentane; C_4.E,1,3 is 1,3-butadiene (E represents a double bond, attached to the first and third carbon of butane); C_2.Q is ethyl alcohol (Q is oxygen, to avoid confusion with zero); B6_2 is naphthalene (two benzene rings, B6, fused); B6ZN is pyridine (Z indicates substitution, in this case of one C in benzene by N). Such examples are simple, but complexities soon arise in ciphering structures containing several rings, bridged rings, mixed assemblages of rings and chains and so on, and new rules and conventions have to be devised for these. Among the wonderful ciphers quoted is that for oxytocin, a complex polypetptide, which contains (I counted them) 179 signs and symbols, including full stops and commas, each of which is significant. Deciphering comes to resemble working out a jigsaw puzzle since, with a cipher starting with a number of rings, one has for some time no idea how these are going to be connected in the final structure. Nevertheless, it has been shown that ciphering can be done and the ciphers printed (proof correcting must be a nightmare).

The questions arise, when and how are the ciphers to be used? A few suggestions are made, for example, to use them for differentiating compounds in the major divisions of a formula index. No doubt Dr. Dyson and his colleagues are studying this aspect and will eventually publish their detailed proposals. Ciphering and deciphering will probably be a specialized task in libraries and information centres. The summit of achievement would be an electronic brain to relieve human effort.

E. H. RODD

NEW BIOCHEMISTRY

Annual Review of Biochemistry

Vol. 27. Edited by J. Murray Luck, in association with Frank W. Allen and Gordon Mackinney. Pp. vii+775. (Palo Alto, Calif.: Annual Reviews, Inc., 1958.) 7 dollars.

PROBLEMS that arise from the spate of scientific literature in the world, and in particular in biochemistry, are very real; but at the present time no comprehensive treatment of the problem can be foreseen. Nevertheless the volumes of "Annual Reviews" which appear each year make a sturdy attempt to make a real contribution to the solution of the problem of the digestion of knowledge. As biochemistry draws its pabulum from an ever-widening field of activity the efforts of a reviewer are attended by increasing frustration. The "Annual Review of Biochemistry" is the oldest of the "Annual Reviews" published in California. This twenty-seventh annual volume manages to fashion the torrent of publications in nearly twenty different aspects of the subject into some sort of smooth-flowing stream. Clearly it is not possible to please all the readers all the time, and the specialist can always find material to criticize; but there can be no doubt whatever that the "Annual Review of Biochemistry" is of the greatest importance to biochemists all over the world.

In the present volume, apart from chapters dealing with vitamins, hormones, and the metabolism of protein, fat, and nucleic acids, there are sections concerned with the "Biochemistry of Viruses" (G. Schramm), "Biochemistry of Cancer" (H. E. Skipper and L. L. Bennett, jun.), "Chemistry and Biochemistry of Antibiotics" (E. B. Chain), "Biochemistry of Fishes" (H. L. A. Tarr), "Metabolic Antagonists" (W. Shrive and C. G. Skinner), "Enzymatic Metabolism of Drugs and other Foreign Compounds" (B. B. Brodie, J. R. Gillette, and B. N. La Du). J. A. Stekol again reviews "Biochemistry in the U.S.S.R.".

There is a prefatory chapter, entitled "Impressions of an Organic Chemist in Biochemistry" by Hans T. Clarke, in which the importance of chemistry as a background to biochemistry is particularly emphasized. As an illustration of this thesis one can refer to the review of "Proteolytic Enzymes" by G. H. Dixon, Hans Neurath, and J.-F. Pechère in this volume, which has the conciseness and clarity that one expects from Dr. Neurath and his colleagues. The fact that one is now able to illustrate the activation of trypsinogen and chymotrypsinogen in terms of chemical structures, and can formulate processes which occur at the active centre of proteolytic enzymes by reactions of a chemical type, well illustrates the advances in this aspect of biochemistry. On the other hand, the discussion of "Newer Developments in Relation to Protein Biosynthesis" by H. Chantrenne is one that is at the heart of the dynamic aspects of biochemistry and as yet contains little that can be formulated in purely chemical terms. At heart a biological subject, biochemistry can snatch from the rapidly moving stream of life, systems, bits of tissue, organelles and subcellular particles of all sorts which in their behaviour seem initially to be far from the sort of chemistry that can be discussed in terms of known processes. But the biochemist reduces to manageable proportions the number of the uncontrolled features of the system, and although the processes which ultimately emerge for analysis may be complex they can be treated in terms of chemical reactions. To many, however, the most exciting part of the line of development lies in the early stages. But whichever stage of development is the primary interest of the reader, he will find much to take his attention in this volume of the "Annual Review of Biochemistry".

F. G. YOUNG

FURTHER ADVANCES IN ENZYMOLOGY

Advances in Enzymology and Related Subjects of Biochemistry

Vol. 20. Edited by F. F. Nord. Pp. vii+488. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1958.) 12.50 dollars.

ANOTHER excellent volume of "Advances in Enzymology" contains articles by biochemists from Australia, the United States, Britain, the U.S.S.R., The Netherlands, Sweden and Switzerland; fourteen enzymes are reviewed in some detail, and a number of general topics are also discussed.

There are two reviews on single enzymes by workers who have been personally responsible for much of the recent research described: by Prof. H. Theorell on "Liver Alcohol Dehydrogenase", and by Dr. A. Gottschalk on "Neuraminidase". The first describes some recent kinetic studies, particularly those using fluorimetry, a technique which is critically discussed, and relates them to the picture of alcohol dehydrogenase mechanism developed earlier by Prof. Theorell in collaboration with Dr. B. Chance. The second review is particularly devoted to the chemistry of the substrates concerned, sialic acids.

Prof. H. M. Kalckar discusses the enzymes involved in the metabolism of uridinediphosphogalactose, and the function of this compound in animals and bacteria. Drs. Vischer and Wettstein list the enormous range of transformations of steroids carried out by micro-organisms; few of these have yet been associated with isolated enzymes, and it is clear that this will be a fruitful field for the enzymologist. Drs. Deuel and Stutz discuss pectic substances and their breakdown, the emphasis being placed on the chemistry of the substrates rather than the enzymes.

A particularly important review is that of Prof. E. C. Slater on "The Constitution of the Respiratory Chain in Animal Tissues". There is still a great deal of uncertainty about several parts of the oxidation chains in animal mitochondria, and the more controversial points are clearly and persuasively discussed. Powerful arguments are urged, for example, against the view that cytochrome *b* is not involved in succinate oxidation, and against the participation of vitamins E and K in the main coenzyme-linked chain. The nature of the cytochrome reductase reaction and the function of the other cytochromes are further topics dealt with in detail; the importance of cytochrome c_1 is emphasized.

Two articles deal with the mechanism of enzyme action. Drs. Davies and Green give a clear and concise account of recent work on the mechanism of cholinesterase, especially that stemming from studies on the inhibition of the enzyme by diisopropyl fluorophosphonate. They conclude that a great deal remains to be done, particularly in explaining the differences between individual enzymes sensitive to diisopropyl fluorophosphonate which appear to have considerable similarities in amino-acid sequence at the active centre. This article may be usefully read with that of Drs. Barnard and Stein, who discuss the role of histidine in the active centres of enzymes. The chemistry of imidazole derivatives is described in detail, and the article will be of use to the many enzymologists who speculate on these matters.

Much has been written in recent years from the enzymic point of view about mitochondria and other structures in animal cells, but less has been written about plant sub-cellular structures. The gap is well filled by an account by Prof. Sissakian of the "Enzymology of the Plastids". Many enzyme systems besides those directly concerned with photosynthesis have been detected in chloroplasts, and these enzymic results are highly significant when considering the function of these bodies.

A more metabolic topic is dealt with by Dr. Kretovich, who discusses the importance of glutamine and asparagine in the nitrogen metabolism of the plant, in protein synthesis and so on. Prof. Werner Kuhn, in an article entitled "Optical Activity and Aging", develops his earlier ideas on asymmetric synthesis and loss of optical purity. Finally, the usual article on some topic on the fringe of enzymology is by Drs. Tanner and Beesch on the interesting results so far obtained by the use of antibiotics such as streptomycin in the control of plant diseases.

All in all, the volume will provide good reading for any biochemist for many a long winter's evening.

EDWIN C. WEBB

RADIOACTIVE ELEMENTS

Chemistry of the Rare Radioelements

Polonium-Actinium. By Dr. K. W. Bagnall. Pp. x + 177 + 5 plates. (London: Butterworths Scientific Publications; New York: Academic Press, Inc., 1957.) 30*s*.; 5 dollars.

Uranium and Thorium

By L. Grainger. Pp. viii + 204 + 8 plates. (London: George Newnes, Ltd., 1958.) 25*s*. net.

"CHEMISTRY of the Rare Radioelements" is a specialized book which describes the chemistry of the elements polonium to actinium. It is of interest to note that, of these elements, only radium could be obtained in a pure state and in weighable amounts prior to 1939. At the present time, however, more is known about the chemistry of polonium than any of the others. This is in no small part due to the extensive programme of work carried out by the author during the past few years at Harwell. He is well qualified to write this book, and the standard he has set is surprisingly high considering the meagre amount of reliable published work on which he had to rely.

The author points out that our knowledge of the chemistry of polonium is approaching in extent that of tellurium, its lower homologue in the Periodic Table. This is largely due to the development of new microchemical techniques for handling polonium—and it should be remembered that this still usually represents work with sub-milligram amounts of the element. There are two short chapters devoted to the handling of polonium and radium and actinium. While these are useful, it would have been preferable to confine them in one chapter in which health problems and micro-radiochemical techniques were discussed in somewhat more detail.

About half the book is devoted to an exhaustive treatment of the chemistry of polonium, and this is a valuable contribution to all inorganic chemists. It is to be hoped that more work, of similar calibre, will be published on actinium. Thus, while milligram quantities of actinium metal have been prepared, most of the solution chemistry is based on tracer scale work, and this can be notoriously misleading. A reason for the small amount of work with actinium is, of course, the difficulty in estimating the isotope actinium-227, because of its weak β, and complicating decay chain. It is surprising the author has not described the use of the α-counting method, which, although requiring a good counter and a pulse analyser, is quantitative and reliable.

This is a valuable reference book and is recommended to all who are interested in the rarer elements.

As the author points out in the preface, "Uranium and Thorium" is intended to provide a reasonably comprehensive picture of the technology of uranium and thorium. It is not intended for the specialist in the metallurgical problems of nuclear power, but it does provide a good background for other scientists and engineers who are either directly concerned with the production of nuclear power or who are just interested in knowing more about uranium and thorium.

The book is, broadly speaking, divided into three parts. The first gives a good account of the occurrence, ore-processing methods and metal production of both uranium and thorium. Then the chemical and more particularly the physical properties of both metals and their compounds are discussed. The last two chapters give a short account of the use of uranium and thorium as nuclear fuels and current trends in fuel-element design in each of the countries interested in nuclear power reactors.

The subject-matter is largely drawn from the proceedings of the 1955 Geneva Conference. Although there has now been a second conference (1958), the book is still surprisingly up to date, and in a second edition it is the chapters dealing with fuel elements which will require more extensive revision. There is also an increasing amount of work being carried out on uranium alloys, for example, with zirconium, molybdenum and silicon, but these receive only a mention. The physical properties of such systems are of interest to the physical metallurgist, and their applications are of special interest to the nuclear technologist. This is a subject which might well merit a chapter to itself.

The author, who at the time this book was written was chief metallurgist to the Industrial Group of the United Kingdom Atomic Energy Authority (he is now chief metallurgist at Harwell), is well qualified to produce such an authoritative account. The book, which is reasonably priced, is strongly recommended to all those interested in the use of uranium and thorium in nuclear power production.

G. R. Hall

SATELLITE RESEARCH

Scientific Uses of Earth Satellites

Edited by James A. Van Allen. Second, revised edition. Pp. x+316. (Ann Arbor, Michigan: University of Michigan Press; London: Chapman and Hall, Ltd., 1958.) 75*s*. net.

THIS book contains an account of experiments which were proposed for the American satellite programme to be carried out mainly during the International Geophysical Year. The various chapters are based upon papers presented at a meeting of the Upper Atmosphere Rocket Research Panel in 1956 by a number of experts in the field of planetary physics. In the first edition, now almost two years old, the experiments were presented as proposals, no satellites having been launched at the time, but since then several of those suggested have been successfully carried out, and others are upon the point of being tried. The second edition now under review, coming so soon after the first, could scarcely be expected to give an account of the results so far obtained, and in fact no new material has been added. Some of the thirty-three chapters have, however, been revised and brought up to date, although this has not altered the total number of pages in the book (316). Revisions may be found in Chapter 1, where, for example, equation 42, p. 9 (which gives the motion of the line of the apsides of a satellite orbit) and the sentence following it, have been corrected. A short addendum has been made to Chapter 24, and in Chapter 33 the discussion of electron accretion by an interplanetary dust particle has been rewritten. There are other changes of a similar nature throughout the book.

The real value of the book, which must be judged to be considerable for those working in the various fields covered, lies in the basic nature of the treatment of each subject. Chapters 1, 5 and 11 discuss in some detail satellite orbits with perturbations due to the Earth's oblateness and atmospheric drag. Further perturbations arising from time and latitude variations of air density and from winds are perhaps too scantily treated to satisfy those interested in the behaviour of the recent *Sputniks* and their rockets. The visibility of satellites and optical tracking problems are the subjects of Chapters 2, 3 and 4, although no detailed mention is made of systems now in use. Satellite instrumentation is covered in a general way in Chapters 6 and 7, power sources being given considerable attention, and particular experiments for the study of the density and pressure of the Earth's atmosphere from a satellite, namely, by an accelerometer recording drag on an orbiting inflated sphere and by an ion gauge of special design, are detailed in Chapters 10 and 12.

The study of the meteorology of the Earth by observing tropospheric weather systems as revealed by clouds is proposed in Chapter 13. The method involves scanning the Earth by narrow-angle photoelectric detectors in a spinning satellite, the detector outputs being telemetered to a chain of ground stations. Chapter 14 describes a method whereby it should be possible to obtain the temperature of the atmosphere as a function of the optical depth by observation of the thermal radiation from the Earth and its atmosphere in the far infra-red.

Four chapters are devoted to investigations in the ultra-violet, which include continuous monitoring of the Lyman alpha-emission from the Sun, observations of the resonance radiation at 1216 A. arising from sunlit hydrogen atoms in interplanetary space, and a prediction of the appearance of the sky in the ultra-violet based upon the study of ultra-violet stellar magnitudes. (No mention is made in the latter of the recent discovery of hitherto unsuspected ultra-violet emitting objects.)

Chapters 20, 21 and 22 are concerned with cosmic rays and auroral radiations. It is here again that a suggestion that the second edition might be somewhat premature could arise, owing to the absence of a discussion of the extremely important Van Allen radiation belt discovered by an American satellite vehicle.

The four succeeding chapters describe proposed geomagnetic measurements of the main field and atmospheric current systems, Chapters 23 and 24 being particularly extensive. Instrumentation is given in some detail, and the importance of establishing the presence or absence of an extra-terrestrial ring current is naturally stressed.

Ionospheric studies occupy five chapters, mainly from the aspect of propagation experiments. Chapter 28 briefly describes possible temperature and electron density measurements using a Langmuir probe.

Chapter 32 reviews work on the acoustic detection of meteoric particles, already carried out using rockets, and recommends the technique for satellites. An alternative meteor detector based on the erosion of resistive elements on the outside surface of a satellite is briefly described in Chapter 8. Interplanetary dust is further discussed in Chapter 33, particular attention being paid to the motion of charged dust particles near the Earth.

Each chapter includes a list of references, in general very extensive, but there is no index. Diagrams are clearly reproduced, and chapter sections and sub-headings well displayed.

E. B. Armstrong

Science and Religion in Seventeenth-Century England

By Prof. Richard S. Westfall. (Yale Historical Publications, Miscellany 67.) Pp. ix+235. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1958.) 36s. net.

IN view of its importance as a landmark in human history, it is not surprising that the seventeenth century is receiving special attention from both historian and scientist. The present book is not merely one of many, it has a distinct approach of its own; indeed, the publishers claim that it "is the first attempt to study systematically the religious opinions of seventeenth-century scientists in the light of their importance to the future of Christianity". As the word "virtuoso" constantly occurs, Prof. Westfall wisely explains that he uses it to describe "one who has a general interest in arts and sciences, or who pursues special investigations in one or more of these; the meaning is further restricted to those interested specifically in natural science". The term appears in the title, the "Christian Virtuoso", published by Boyle in 1690.

The book under review contains many illustrations from the writings of the virtuosi on such subjects as the harmony of science and religion; the harmony of existence; Divine Providence and natural law; the growth of natural religion; reason and faith. Among the familiar names specially mentioned are Robert Boyle, Nehemiah Grew, John Locke, John Ray and Edmond Halley. It is fitting that the concluding chapter of Prof. Westfall's work should be headed "Isaac Newton: A Summation". It begins with an extract of Newton's letter to Richard Bentley, dated December 10, 1692: "When I wrote my treatise about our system, I had an eye upon such principles as might work with considering men for the belief of a deity; and nothing can rejoice me more than to find it useful for that purpose". There are references also in this chapter to Newton's theological writings, and a discussion of his views in relation to those of the other virtuosi.

The inclusion of a "Bibliographical Essay" of some ten pages enhances the value of Prof. Westfall's book, and invites further study of an outstanding period in science, religion and philosophy.

H. D. ANTHONY

Le Système du Monde

Histoire des Doctrines Cosmologiques de Platon à Copernic, Tome 8. Par Prof. Pierre Duhem. Pp. 512. (Paris: Hermann, 1958.) 3,400 francs.

THE posthumous publication of Vols. 6–10 of Pierre Duhem's monumental work "Le Système du Monde" has now proceeded to the eighth volume, being the second of a group of three which is devoted to the physics of the Parisian school in the fourteenth century. The first two chapters (8 and 9) deal with the problems of the vacuum: its possibility, the so-called *horror vacui* of Nature, the movement of bodies *in vacuo*. In the next two chapters (10 and 11) the movement of falling and projected bodies is treated. This is a most important subject in medieval physics, as it contains the germ of modern dynamics. Then the treatment turns to cosmology again: the application of the ideas of the Terminists on celestial motions is discussed and the various attitudes of medieval thinkers towards astrology are reviewed. As was remarked in the review of the preceding volume, we owe a debt of deep gratitude to the editors for the fact that the great work that Duhem left unfinished at his death in 1916 is none the less being completed. In the meantime, however, the study of medieval science has been pursued and our ideas on the subject have notably progressed. It is no longer possible to consider Duhem's statements and opinions as final, as we all were inclined to do when the first volumes of "Le Système du Monde" appeared in the years 1914–17. Nowadays no reader striving after a knowledge of medieval science which is abreast of the time can afford to neglect studying the works of A. Maier. This, however, necessitates some important modifications in Duhem's exposition.

This does not detract from the pleasure of reading him. His style is an admirable specimen of French elegance and clarity from which it is no detraction that some corrections are necessary in the text.

E. J. DIJKSTERHUIS

Benedict de Spinoza

The Elements of His Philosophy. By Prof. H. F. Hallett. Pp. xvi+171. (London: The Athlone Press, University of London, 1957. Distributed by Constable and Co., Ltd.) 25s. net.

THIS is a compact, scholastic exposition of Spinoza's philosophy, the result of profound reflexion on the original texts. There is no evaluative discussion of Spinoza's ideas; Prof. H. F. Hallett has tried to speak only with his master's voice. His book provides a remarkable example of sympathetic understanding, in attitude and intellect, of a lapsed mode of thought, and it will unquestionably be illuminating for the expert in studies of Spinoza—and for those who thought they were experts. But I fear that to the rest the book will remain closed not long after it is opened. The author's scholastic style expresses itself continually in sentences such as, "A perfect primordial being possesses all potency in eternal act; but an imperfect and privative being possesses only the potency that it actualizes, though, as privative, potency is durationally available to it that is not *by it* durationally actualized" (p. 6), which might well discover truths to the initiated but can only baffle the novice for whom the book is confessedly designed. Again, the background to Spinoza's thinking, the patterns and pressures that moulded his mind and the materials that he transformed in his own peculiar way are neither elucidated nor referred to; and the principal scholarly work (by Wolfson) which provides this very background is nowhere mentioned, not even in the bibliographical note. Thus my reaction to Prof. Hallett's mature and careful presentation is one of respect and admiration, mixed with regret at his stylized obscurity and at the absence of historical enlightenment.

PETER NIDDITCH

ESP and Personality Patterns

By Gertrude Raffel Schmeidler and R. A. McConnell. Pp. xiii+136. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1958.) 25s. net.

SOME years ago, at the City College, New York, Dr. Schmeidler discovered that if she asked her experimental subjects whether or not they believed in the possibility of extra-sensory perception (ESP), their subsequent scores showed that the believers' average score was significantly above mean chance expectation, whereas the unbelievers tended to score at chance-level or slightly below. She labelled these two groups the 'sheep' and the 'goats', respectively. Later experiments have amply confirmed this original finding, and it is one of the not very large number of facts in experimental parapsychology that can be regarded as established.

This fact is interesting, since it is not only an addition to the evidence as to the reality of extrasensory perception, but also an indication that there are personality differences correlated with ESP ability It leads to many further questions, some of which are further explored in this book; many of which are indicated but not yet answered. The obvious further question as to a more exact specification of the personality correlates of ESP ability has been tackled mainly with the help of the Rorschach test. Since, however, this test is known to have low reliability, no very certain evidence as to the answer has been obtained or is likely to be obtainable by this means. The suggestion by the authors, that some of the diversity in findings of different investigators of this topic may be due to personality differences between investigators, is an important speculation that awaits experimental verification.

The experimental work of Dr. Schmeidler has until now been scattered in the technical journals. In collecting it in one volume and in obtaining the collaboration of Dr. McConnell (particularly for a needed strengthening on the statistical side), she has done the student of parapsychology a considerable service. The result of this collaboration is an interesting and authoritative account of an important piece of research. R. H. Thouless

The Black Fens

By A. K. Astbury. Pp. xi+217+55 plates. (Cambridge: The Golden Head Press, Ltd., 1958. Distributed in Great Britain and Eire by W. Heffer and Sons, Ltd.) 42*s*.

THIS excellent book is likely to appeal most to the layman interested in finding out more about one of the most distinctive regions of Britain, but also has much of interest to geographers. The first part of the book is concerned with the origins and physical characteristics of the black peats, which since the beginnings of major drainage schemes in the seventeenth century have come to provide Fenland farmers with exceptionally productive soils. But agriculture in the Fens faces a unique combination of hazards. There can be few areas in the world where, within the span of one year, a farmer may have to contend with his soil being flooded in winter and actually catching fire in summer. Since draining, the peat has shrunk many feet while the silt river beds have maintained their original height. These processes make control of surface-water progressively more difficult and the consequences of a failure of flood protection measures more serious. The problems of farming, and of building roads, railways and houses upon the spongy peat are illustrated with a wealth of detail that obviously springs from a long and intimate acquaintance with the area. Particularly to be commended is the use of carefully selected aerial photographs printed opposite sketch maps of the area covered by them, which serve to show the great importance of the "roddhams". These silt beds of ancient water-courses provide the only stable sites for building in the peat region.

In the second part of the book the question of the origin of the Fen waterways is examined. It is remarkable how little is known about most of these ancient channels. After an exhaustive study of many of them, based on considerable field work, the author puts forward a good case for believing that many of them were constructed by the Romans, but rightly points out the difficulty of proving this or any other hypothesis.

The book is well served by many good photographs and sketch maps and a large folding map which shows nearly all the places mentioned in the text. M. A. Morgan

Bone and Radiostrontium

By Arne Engström, Rolf Björnerstedt, Carl-Johan Clemedson and Arne Nelson. Pp. 139. (New York: John Wiley and Sons, Inc.; Stockholm: Almqvist and Wiksell; London: Chapman and Hall, Ltd., 1957.) 70*s*. net.

ANY information concerning the metabolism of strontium-90 must be welcomed at the present time and the authors have presented a valuable account of work carried out in their own laboratories. One chapter is devoted to a discussion of the distribution of mineral salts in bone in which the techniques of microradiography and microinterferometry are fully described. In another chapter the authors discuss the nature of bone salts and the structure of bone tissue, particularly with reference to the ability of the apatite crystals to attract various types of ions by surface adsorption. A calculation of the radiation dose from beta-rays within a plane parallel sandwich of radioactive trabecular bone and inactive bone marrow is described in great detail. It is a pity that the authors did not also include calculations using cylindrical geometry, which might be more applicable in the case of another concentration site of strontium-90, namely, Haversian systems.

In the discussion summarized at the end of the book, the authors deduce a value, 0·1 μc., for the maximum permissible burden of strontium-90 in human beings. Since this is 10 per cent of the value recommended by the International Commission on Radiological Protection for occupationally exposed persons, the authors' arguments have been carefully examined. The radiation dose within a microscopic tissue element in bone contaminated with the radioisotope has been discussed in relation to an assumed cancer dose of 1,000 r. of external radiation. There is, however, no discussion about the importance of the relationship between dose or dose-rate and the incidence of cancer, or of the importance of the volume of tissue irradiated. A comparison between a body burden of 0·1 μc. strontium-90 and an unspecified burden of radium known to produce malignancies is, of course, valueless. There is in any event no comment about the effect of alpha- and beta-particle range on the non-uniformity of radiation-dose or about the relative biological effectiveness of the two radiations. A second calculation assumes that a dose of 10 r. to a microscopic site in bone marrow will produce detectable blood changes. In the absence of a more detailed discussion on the type of blood damage expected, on the dose-response relationship and on the effect of varying the time over which the dose is given, this discussion is also without value.

It is unfortunate, therefore, that the authors, who obviously have a valuable contribution to make in this field, did not make a more careful survey of the present position before attempting to suggest a new level for the maximum permissible burden of strontium-90. J. Vennart

Lebensgemeinschaften der Landtiere

Ihre Erforschung unter Besonderer Berücksichtigung der Zoozönologischen Arbeitsmethoden. Von Dr. Janos Balogh. Zweite verbesserte und erweiterte ausgabe des 1953 erschienenen werkes "Grundzüge der Zoozönologie". Pp. ii+560. (Budapest: Akdemiai Kiado, 1958.) n.p.

THE Budapest school of terrestrial biology is well known for its work on the ecology of the soil fauna. Dr. J. Balogh's book is of value because it introduces this important work to a wider audience, but it is perhaps of even greater significance as a synthesis of theory and of methods of analysis current in the different world schools of community ecology.

The first edition of this book was a stimulating and thoughtful analysis of animal synecology, logically beginning with definitions of the community (biozonose) and later departures from earlier concepts, followed by an analysis of the community, its detection and delimitation, its structure and subdivision, its inorganic and living content, spatial and temporal changes, the food chain and production biology and finally a consideration of schemes of analysis and study in practical use. The new edition has been extended so that it is now an up-to-date and cosmopolitan account of this field. To this have now been added sections which provide the most extensive review now in print of methods for the collection, examination, culture and extraction of terrestrial invertebrates, supplemented by sections on vertebrates by Turček and on agricultural land faunas by Heydemann (of Kiel). Although statistical aspects of sampling are not considered, no one who already works in this field can fail to find some useful details of technique which will be new to him, and no one entering the field could be referred to a more complete résumé of methods. A. MACFADYEN

The Dawn of Life

By Dr. J. H. Rush. Pp. 258. (London: English Universities Press, Ltd., 1958.) 15s. net.

DR. J. H. RUSH has made a brave attempt to present a comprehensive account of the origins of living matter in terms intelligible to those without much knowledge of physics and chemistry. He has a rare skill for interpretation, and is adept both at choosing the right word and in using a suitable figure of speech for illuminating his text. Yet it is doubtful if his book can be called more than a gallant failure. Although the grand strategy is clear and well-conceived, the tactics are scarcely suitable to achieve the objective.

Besides descriptions of the hypothetical beginnings of the universe and the earth, the author includes accounts of the physico-chemical origin of living things, theories of evolution, life on other planets and the emergence of mind. All this, supported by the relevant laws of physics and a description of chemical theory, does not make for easy reading even for those with some knowledge of chemistry and physics. Like so many books intended for the general reader, the author has attempted too much in too short a space. If the first three chapters had been expanded and written with the intelligent secondary modern schoolboy in mind, Rush might well have produced an outstanding popular scientific work. He is to be congratulated for this attempt, and should be encouraged to write other popular works with the belief that sometimes greater clarification is achieved more by omission than commission. T. H. HAWKINS

An Introduction to Tropical Agriculture

By Sir Harold Tempany and D. H. Grist. Pp. xvi+347+12 plates. (London and New York: Longmans, Green and Co., Ltd., 1958.) 40s. net.

THE late Sir Harold Tempany has attempted "to provide a logical and coherent account of the background to agriculture in the tropics", which his co-author believes "should be of great value to students, agricultural officers and administrators" in these areas. Sir Harold, who had had a wide experience of tropical agriculture, died before completing his task, which was then entrusted to Mr. D. H. Grist. With the increasing demand for tropical agricultural products and the urgent need to improve methods of land use and production and thereby raise the living standards of many tropical peoples, such a book should be very welcome, particularly as no such account had been published for some years. Unfortunately, the volume under review does not reach a standard adequate to meet this need.

The book is very uneven in content. Much space is wasted in explaining simple facts which are more adequately dealt with in the numerous elementary text-books on temperate agriculture. Thus a whole chapter is devoted to fertilizers in which the role of the major elements in plant nutrition and the nature of the common fertilizers are explained, while shifting cultivation, the most important system of farming in the tropics, with its wide range of variation and modern modifications, is dismissed in one page. The treatment of many subjects is so generalized, uncritical and superficial that it provides little information of practical value and some of it is inaccurate. It is possible to quote many statements of the obvious which might well have been omitted, such as "irregularities in the amount and incidence of rainfall cause great difficulties and these naturally increase as the drier regions are approached", which appears in almost identical words no less than three times in two consecutive pages. J. W. PURSEGLOVE

Flora of Manitoba

By H. J. Scoggan. (National Museum of Canada Bulletin, No. 140.) Pp. v+619. (Ottawa: Queen's Printer, 1957.) 5 dollars.

THE province of Manitoba is larger than the United Kingdom and is centrally placed in Canada both physically and botanically, but by a trick of fate it had remained uncovered by the three great manuals dealing with the flora of temperate North America. This neglect is now remedied by the excellent book under review. The major vegetation types of Manitoba are prairie (now mostly under cultivation), swamp and dry sandy forest near the Great Lakes, boreal forest, tundra forest and arctic tundra in the extreme north-east. These are briefly described, with their climates, and are illustrated by photographs. The rest of the book, apart from a bibliography, tabular classifications of species and lists of additions and exclusions, is the Flora proper, which follows many conventional lines.

There are no descriptions of individual taxa, and critical taxonomic comment is cut to the minimum, but the specific keys seem unusually ample and satisfactory, and there are many references to recent generic revisions. Careful notes are given on habitat and on distribution both within and outside the area, the "first report" of each taxon is always cited and so too, usually, are the "earliest collection seen" and the northernmost collection. Hybrids are omitted:

otherwise, there would surely be some mention of this proclivity among the 28 species of *Salix*. 1,417 species of vascular plants, including 193 introductions, are found in Manitoba, the largest families being the Cyperaceae (159 native species), Compositae (144) and Gramineae (114). No less than 118 species of *Carex* are listed, but there is no genus comparable, at any rate in treatment, to the British *Rubus* and *Hieracium*. The author is to be congratulated on a valuable piece of work which will reward the close scrutiny of British and European botanists concerned with the preparation of Floras. N. Y. SANDWITH

Diseases of Domestic Animals in New Zealand

Prepared by the Technical Committee, N.Z. Veterinary Association, Inc. Pp. x+240. (Wellington: Editorial Services, Ltd., 1958.) 35*s*.

THIS book is not for the arm-chair reader but for the busy veterinary surgeon needing some form of reference to which he can turn for essential and up-to-date factual information. It deals with the significant diseases of domesticated animals and poultry, only as they occur in New Zealand, grouped under the headings, bacterial, viral, protozoal, fungal, parasitic, nutritional and metabolic, those caused by poisons, and miscellaneous. Under each heading, the diseases are listed alphabetically, and each disease is covered in one or, at most, two pages in précis form through the use of subheadings, for example, species affected, notifiable, distribution, occurrence, herd incidence, etiology, mode of infection, signs, pathology, diagnostic aid, prognosis, treatment, etc. The brevity of style and standard form of presentation have been used deliberately for ease of reference, so that one is presented with an accurate and authoritative summary of the disease position in New Zealand. Some minor criticisms could be made. As one example, it is a little distracting to find that all the intestinal nematodes of a particular host animal are treated as causing one disease. Such criticism, however, is trifling and amply compensated by the wealth of information presented so simply and concisely and with so few errors. There is an index of eight pages which could, with advantage, have contained more entries such as helminths, cestodes, trichostrongyles or even worms, to mention a few. The eight appendixes listed in the contents table were not included in the reviewer's copy. J. N. OLDHAM

Birds of Cyprus

By Dr. David A. Bannerman and W. Mary Bannerman. Pp. lxix+384+31 plates. (Edinburgh and London: Oliver and Boyd, Ltd., 1958.) 63*s*. net.

ONE has come to expect volumes from Dr. Bannerman that are sumptuous as well as scholarly, and here he and his wife present another. The scale may even seem luxurious for the avifauna of so small a territory, but Cyprus has a considerable ornithological literature and its bird-life shows interesting features. The island lies on the fringe of the tremendous migrations of the Levant, and more than half its 333 recorded species are purely birds of passage; others are winter visitors. Some 70 species breed, a third of them as summer visitors: among the residents, 14 belong to races peculiar to the island. It is remarkable that, in spite of extensive forests, there are no woodpeckers and no nuthatch.

There are references to birds going back to the fourteenth (falconry only) and sixteenth centuries; serious ornithological publications date from 1787 onwards; in the past few years ornithologists in the Armed Forces have added numerous records; the Bannermans themselves spent some months on the island in 1954 and in 1957–58 for the purposes of the book, and they have drawn both on the other sources and on their own observations. For the benefit of the student in Cyprus, there are notes on identification (with numerous figures) and on extra-limital distribution: Greek and Turkish names of species are given. For ornithologists elsewhere, the information about local status is of importance as a contribution to a wider pattern. The illustrations include some fine colour plates by D. M. Reid-Henry and Roland Green. LANDSBOROUGH THOMSON

British Fermentation Industries

By J. M. Whitmarsh. Pp. xiv+133. (London: Sir Isaac Pitman and Sons, Ltd., 1958.) 25*s*. net.

THIS condensed account of industrial fermentations, which is restricted to British practice, embraces both old and new processes, but deliberately excludes consideration of the potable and antibiotic industries. The manufacture of industrial alcohol, acetone and butanol, lactic acid, vinegar, baker's yeast, citric acid and of sorbose is described as illustrative of the older processes. The inclusion of the obsolescent industrial alcohol and acetone-butanol processes, both of which have been superseded by synthetic chemical processes, is justifiable in that they have provided, over a number of years, fundamental knowledge and technological experience which has facilitated the rapid large-scale development of newer processes. It is especially valuable to have good condensed accounts of these new, less-familiar, processes as exemplified by those by which vitamin B_{12}, riboflavin and dextran are manufactured and by which difficult steroid transformations may be effected; for it is in these fields, as well as in that of antibiotic production, that the fermentation industries may be expected to continue to develop and prosper. In all, Dr. Whitmarsh has written a very useful account of the subject within his self-imposed restrictions. Despite compression, there is adequate technical detail to provide a good introduction to the fermentation industries for new entrants, of whom the biochemical engineer should be particularly mentioned. There are few errors of fact or of typography, but the taxonomically minded will boggle at reading that *Euglena* is a mould (p. 82) and that *Rhizopus nigricans* is a *Mucor* species (p. 115).

Textbook of Biochemistry

By Prof. Benjamin Harrow and Prof. Abraham Mazur. Seventh edition. Pp. ix+557. (Philadelphia and London: W. B. Saunders Company, 1958.) 52*s*. 6*d*.

PROF. Benjamin Harrow has a long and honourable career as a writer of text-books of biochemistry. In 1935 he and Carl P. Sherwin collaborated as joint editors of a "Text-book of Biochemistry" to which chapters were contributed by a number of authorities. This book set a standard of clarity and breadth of information which was upheld later by a text-book with Prof. Harrow as the sole author, of which editions have already appeared ranging from the first in 1938 to the sixth in 1954. For the sixth edition Prof. Harrow was joined by Prof. Abraham Mazur as joint author, and now a seventh edition is called for, as might be expected, four years after the sixth.

Since the rate at which biochemistry develops continues alarmingly, each edition of a general text-book needs substantial revision, and the new edition of this standard work has been widely revised. In particular, the chapters on nucleoproteins and the various phases of intermediary metabolism have been rewritten, and the previous one on photosynthesis replaced by sections in the chapters on carbohydrate chemistry and on carbohydrate metabolism. It is a reflexion of the coherence of growing knowledge that changes of this sort now are almost inevitable. The former two chapters on digestion and adsorption have been incorporated into one, while that with the title "Detoxication" has been quite properly replaced by one called "Metabolism of Organic Chemicals".

With the immense growth of knowledge of which account is taken it is surprising, but welcome, that this edition should be a little smaller than the previous one. The pages of text, numbering more than 500, are still eminently readable, and although some sections naturally are less up to date than others, on the whole the authors keep surprisingly well abreast of current knowledge. They are to be congratulated on maintaining a standard text-book in such a uniformly good state. F. G. YOUNG

General Biochemistry

By Prof. Joseph S. Fruton and Prof. Sofia Simmonds. Second edition. Pp. xii+1077. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 144*s*. net.

THIS book gives a very complete and readable account of the chemistry, physical chemistry and intermediate metabolism of the important chemical constituents of the living organism. The chemical chapters on proteins are extensive and provide a most detailed and informed survey. A chapter on elementary thermodynamics with a useful introduction to the second law and the concept of free energy is also included.

The whole of the subject-matter is introduced and developed as an experimental science, and sufficient experimental details are given for a proper appreciation of the theoretical discussions and generalizations. In many cases the experimental methods are described and explained in some detail, and this is especially true of the more recent methods of chromatography and isotopic tracer techniques.

All the usual metabolic sequences and interconversions of biological syntheses and degradation are ably discussed, and generally the most recent views and enzymic steps are included. These metabolic surveys are mainly concerned with animal biochemistry, although there is a very good chapter on photosynthesis by green plants.

The book is thus an excellent and comprehensive introduction to the subject, and since it is well documented it may well serve for a few years as a reference book to some parts of biochemistry. However, as a text-book for use by students in Great Britain it has two disadvantages. One of these is its very high price and the other is the level at which it is written. For use in most elementary courses the book is too detailed, especially for those students who do not wish to specialize in the subject; while the advanced student, although finding the book very useful, must have access to the many adequate reviews and whenever possible direct reference to the important original papers. D. H. NORTHCOTE

Metals and Enzyme Activity

Biochemical Society Symposium No. 15 held at the University of Leeds on 13 July 1956. Organized and edited by E. M. Crook. Pp. v+102. (Cambridge: At the University Press, 1958.) 21*s*. net cloth bound; 15*s*. net paper bound.

IN the Biochemical Society symposium held at the University of Leeds, in 1956, inorganic chemists and biochemists joined in discussing aspects of the functions of metals in enzyme systems. This book contains the papers that were presented at that meeting, together with the discussions which followed.

The symposium opened with a short introductory paper by R. S. Nyholm describing recent work on metal ligand bonds, a topic which was developed further in a paper by L. E. Orgel on the solution chemistry and structural chemistry of some metals important in enzyme activity. Some suggestions on the mode of action of metals in the catalytic hydrolysis of peptide bonds were made by B. R. Rabin, who gave a short account of conflicting views on the nature of the enzyme-metal-substrate complex. Later in the session, F. C. Happold and R. B. Beechey considered the univalent metal ions as non-specific activators of enzymes and attempted to explain their function. The role of metals in metallo-flavoproteins was summarized by F. Bergel and B. C. Bray, who discussed the involvement of the metals in electron-transfer reactions. The symposium ended with a paper by E. C. Slater describing briefly and conveniently the classification and properties of the cytochromes.

This meeting of chemists and biochemists has made a valuable contribution to this fascinating problem, and it is unfortunate that more than two years have passed before the papers appeared in print. O. T. G. JONES

Electronic Theory and Chemical Reactions

An Elementary Treatment. By R. W. Stott. Fourth edition. Pp. viii+112. (London and New York: Longmans, Green and Co., Ltd., 1958.) 12*s*. net.

THE author was one of the first to attempt a simplified account of the theories of reaction mechanism and his success may be measured by the fact that this is a fourth edition of a book which first appeared a little more than fifteen years ago. This edition retains the very simple treatment which characterized the earlier editions, together with additions and emendations. The bibliography which accompanies each chapter has also been extended and is now, in some cases, of considerable proportions.

The content of any book is largely a matter for the author, and his success in this case suggests that he caters very satisfactorily for his intended readers. Nevertheless, I feel that some change of balance in the material might be made in a future edition. There is, for example, no discussion of hydrogen-bonding, while about four pages are devoted to a demonstration of the equivalence of the hydrogen atoms in benzene. This latter, formal demonstration might be curtailed or even eliminated by mentioning the Raman and infra-red spectral evidence that this molecule is planar and centro-symmetrical. The X-ray evidence upon hexamethylbenzene, or benzene itself, may be quoted instead. Inclusion of the former topic would do much to remove the difficulty that not all covalently bonded compounds are of a high volatility, 100 per cent sulphuric acid being a particular example.

A few minor errors have also appeared in the text. Thus, the omission of a negative charge from the extruded group X^- in the bimolecular substitution process on p. 53, the reference to a diagram as on p. 65 which is really on p. 67, the possible confusion which may arise (p. 85) by describing Cl^- as a chlorine ion instead of the established chloride, the more so as possibly a Cl^+ is involved in this reaction, and finally, the reference p. 62 should be to Braude and not Brande.

The book is well and pleasingly produced and adequately indexed. One can confidently look forward to the appearance of a further edition within the near future. R. I. Reed

Fundamentals of Optics

By Prof. Francis A. Jenkins and Prof. Harvey E. White. Third edition. Pp. vii+637. (London: McGraw-Hill Publishing Company, Ltd., 1957.) 64*s*.

In its third edition, this excellent text-book has been largely rewritten to include recent developments in both experiment and theory, and to bring the treatment into line with modern ideas on the teaching of the subject. There can be few books ranging from the detailed drawing-board computations of ray-tracing, and the analytical discussion of third- and fifth-order aberration, to the scintillation counter and its possible use to examine simple interference experiments in the light of the uncertainty principle. The mathematical proofs of formulae have been presented more concisely, and the complex-quantity notation used in the wave-theory section of the book makes for easier reading. The diagrams, many of which illustrate graphically the physical meaning of an analytical expression, are really helpful in supplementing the mathematics. The book is well produced, and can be recommended as very good value. G. R. Noakes

Nuclear Magnetic Resonance

Annals of the New York Academy of Sciences, Vol. 70, Article 4. By H. S. Gutowsky and seventeen other authors. Pp. 763–930. (New York: New York Academy of Sciences, 1958.)

A conference on nuclear magnetic resonance was held by the New York Academy of Sciences in November, 1957, and the papers presented at this meeting have now been published. The papers are concerned with some of the more recent applications of nuclear magnetic resonance to chemical problems. The first part deals with the fundamental interactions which determine the nuclear resonance line-widths and shapes, their chemical shifts and multiplicities. The origins of these interactions are summarized by C. P. Slichter, and H. S. Gutowsky gives an excellent review of the chemical interpretation of chemical shifts and spin – spin coupling constants and of the principles of the analysis of the sometimes complex high-resolution spectra. This is followed by a description by Schneider, Bernstein and Pople of the detailed analysis of the very complex spectra of pyridine and its deuterium derivatives. The study of hindered internal rotation in organic molecules is discussed by W. D. Phillips, and of chemical exchange kinetics by W. G. Schneider and L. W. Reeves. P. C. Lauterbur describes experiments to explore the use of the spectra obtained from carbon-13 nuclei in natural abundance in organic compounds. The use of high-resolution nuclear resonance spectra to study really complex organic molecules is illustrated by F. C. Nachod and by M. Saunders and A. Wishnia. The complementary use of nuclear magnetic resonance and infra-red spectra is discussed by H. Finegold with especial reference to the chemistry of organic compounds of phosphorus, and R. B. Williams gives a detailed and authoritative discussion of the conditions necessary for the use of nuclear magnetic resonance for quantitative analysis.

For the reader with some acquaintance with the subject of radio-frequency spectroscopy, this collection of papers provides an excellent survey of the uses of the method in chemistry. R. E. Richards

The Preparation of Programs for an Electronic Digital Computer

By Dr. Maurice V. Wilkes, Dr. David J. Wheeler and Dr. Stanley Gill. Second edition. (Addison-Wesley Mathematical Series.) Pp. xiv+238. (Reading, Mass.: Addison-Wesley Publishing Company, Inc.; London: Academic Books, Ltd., 1957.) 60*s*.

This is a second and enlarged edition of the book first published in 1951. As before, the main emphasis is on the preparation of programmes for *Edsac* I together with the specification and detailed coding of selected library sub-routines. Additional material has been added, however, on machines possessing different order codes and different input and output systems, while twelve pages are devoted to automatic programming and the concept of 'floating addresses'.

The book is in three parts, its basic plan following that of the first edition. Part 1 gives all the information required to prepare a programme for the *Edsac* and deals in general terms with other machines. Part 2 specifies the most important of the *Edsac* library sub-routines and Part 3 gives the complete list of instructions for selected sub-routines.

The book will be of most value to the beginner who wishes to learn some of the principles underlying programming. In particular those intending to programme *Edsac* I will welcome the revised description of the order code, in which important changes have occurred since the publication of the first edition. These include the provision of a *B*-register, the unconditional jump order and output on to punched paper tape.

The use of the machine is clarified by a number of simple examples, and exercises—many with specimen solutions provided—are set to enable the reader to test his understanding of the machine.

The book has a more attractive layout than previously, and the authors are to be commended on this revised edition. E. L. Albasiny

Fourier Transforms and X-ray Diffraction

By Prof. H. Lipson and Dr. C. A. Taylor. Pp. vii+76. (London: G. Bell and Sons, Ltd., 1958.) 18*s*. 6*d*. net.

This is a well-prepared book at a comparatively moderate price, suitable for third-year undergraduates and junior postgraduates, but containing much that will interest senior research workers and university teachers. When the theory of X-ray diffraction by crystals is approached by way of the Bragg relation, the transition to the reciprocal lattice can often seem highly artificial, and the idea of the molecular transform may never be reached at all, especially by the non-mathematically inclined. The authors argue convincingly that if what is interesting is the content of one unit cell, then it is more logical and may be more fruitful to begin with the transform and examine its modification by the crystal lattice. The means of doing this optically, which is a subject of which they have special experience, is only briefly mentioned in an appendix, and is to be dealt with in a further publication. Applications of the Fourier transform theory to the trial-and-error method, to sign determination, to the direct recognition of molecular features, to structural imperfection such as stacking disorder, to the effects of crystal size and shape and other problems are given brief but stimulating consideration. In dealing with temperature effects, however, the impression is given that the diffuse regions around all reciprocal lattice points are similar and parallel, and this is an error which should be corrected in the next edition.

Kathleen Lonsdale

Introduction to Difference Equations with Illustrative Examples from Economics, Psychology and Sociology

By Prof. Samuel Goldberg. Pp. xii+260. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 54s. net.

In recent years new developments in the social sciences, economics, psychology and sociology have involved an increasing use of mathematics, and a branch of the subject which has found widespread application is the theory of difference equations. The book under review covers this topic and is "primarily intended for social scientists". The exposition is at an elementary level, and the style is sufficiently easy for the ordinary undergraduate to understand the methods for solving difference equations and to learn of some of the recent research applications such as inventory analysis and probability models for learning.

Two features of the book deserve special mention. There are a number of worked-out examples to illustrate the text and more than 250 problems with answers, so that the work should be very useful as a text-book. There are also many references to recent research papers, where the research student may find more detail. Altogether the book gives the impression of having been carefully written and with the student very much in the mind of the author.

Some topics of a relatively advanced nature are gently introduced towards the end. These include matrix methods, generating functions, a characteristic-value problem and the analysis of equilibrium and stability. The latter, unfortunately, is only discussed in the case of a second-order auxiliary equation, and the reviewer believes that it would have been useful to discuss the case of higher-order equations, via the Routh-Hurwitz determinantal conditions.

L. S. Goddard

An Introduction to Combinatorial Analysis

By John Riordan. (A Wiley Publication in Mathematical Statistics.) Pp. xi+244. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1958.) 68*s*. net.

The classical text-book by Netto, "Lehrbuch der Combinatorik", published in 1901, is unknown to most present-day mathematicians; and the subject-matter, namely, problems of enumeration, has been generally out of favour for two decades or more. Now the book under review appears and new life is thereby injected into the subject. The author has given a careful exposition of various developments of recent decades which have until now remained locked away in scattered journals and proceedings. Perhaps the most valuable aspect of the present work is this bringing together of material and the connected account of a topic which is important in various branches of applied mathematics and probability theory, as well as in certain parts of pure mathematics where there is still an interest in finding 'the number of ways'.

For the contents an introductory chapter on permutations and combinations is followed by an important chapter on generating functions, including the polynomials of E. T. Bell. Then there are chapters on the principle of inclusion and exclusion, cycles of permutations, distributions and occupancy. The next chapter, which comes near to parts of graph theory, is concerned with partitions, compositions, trees and networks. The explicit results find application in the theory of electrical networks and in systems engineering, including coding problems in data transmission. The last two chapters cover permutations with restricted position.

The book includes a large number of problems and explicit results at the end of each chapter. These are for the serious student who wishes to know 'how to do it' rather than what has been done. They are, as the author says, "put in a form to aid rather than baffle", and they assume, as does the text itself, a considerable degree of mathematical maturity on the part of the reader.

L. S. Goddard

Technology of Instrumentation

By Prof. Eric B. Pearson. (Applied Physics Guides.) Pp. 202. (London: English Universities Press, Ltd., 1958.) 25*s*. net.

Instruments are indispenable in modern scientific and engineering work, and an understanding of the principles of operation is essential if correct results are to be obtained. The main emphasis is on the performance of the standard laboratory milliammeter type of instrument. The static and dynamic characteristics of instruments are explained and the importance of a knowledge of the transient response of an instrument is demonstrated. Electronic instruments are not included, and it is unfortunate that the cathode-ray oscilloscope is omitted since it is valuable where non-sinusoidal wave-forms are to be measured.

The application of instruments to control systems occupies the larger part of the book. The principles of servomechanisms are dealt with at length, and topics discussed include velocity feedback, reduction of velocity lag and general conditions for stability. A chapter on servomechanism components describes a number of elements used for measuring the difference in angular position of output and input shafts of a mechanism. This is followed by a description of electronic and hydraulic amplifiers and motors for supplying power to an output shaft. The final chapter on instrumentation of mathematics describes a number of electrical and mechanical devices for integrating and multiplying.

The book forms a useful introduction for students in the subjects of instrumentation and servomechanisms, but it is unfortunate that the author has not considered a wider range of measuring instruments and measurement principles.

R. L. Grimsdale

(*Continued from p.* 950)

Ano-dorsal fin formula. Adult specimens collected by Frost in Kenya have shown that this character cannot be used alone to distinguish between even adult *A. n. labiata* and *A. mossambica*, although *A. b. bicolor*, the 'short-finned eel', is immediately recognizable by this method and is not represented in the present material. Figures for this character are given in Table 1.

Vertebral counts. In both the Tana and the Sabaki specimens the vertebral counts are rather low. Thus Barnard[6] considers 100–105 normal for *A. mossambica*, and Frost (*in litt.*) 107–115 for *A. n. labiata*. But even with X-ray photographs, such counts are difficult in the smaller specimens and an error of two or perhaps three vertebræ is possible.

The eighteen Tana River elvers have been referred to *A. n. labiata* and the single Sabaki River elver is considered to be *A. mossambica*, the first true elver to be recorded in Kenya. There is no doubt from the abundance of adults in the river at certain times of the year that elver and post-elver stages must migrate upstream in considerable numbers, and further observations at the Merilla Barrage and the construction of an elver trap on the Ragati River (Tana system) at our Inland Fishery Research Station should reveal much of interest.

We are grateful to Dr. W. E. Frost for additional adult measurements and for helpful comment on these observations, and we are especially indebted to Dr. Geoffrey Kelham, of Nairobi, for some strikingly successful X-ray photographs of these difficult small subjects.

'Bat Erosion' at Niah Great Caves

AT the Great Caves of Niah, Sarawak, West Borneo[1], there is a relatively soft coral limestone of Miocene date in which these vertical cavities are common, and as in Trinidad[2], found where there are no stalactites. On the other hand, the rock in these places is damp and there may often be a ring of very slowly forming drips around the mouth of a cavity. Moreover, only small family groups of *Miniopterus witkampi* regularly use these sites as roosts, rarely more than five at once, hanging in a bunch from the top-dead-centre[3]. It is doubtful whether the scrabbling action of these small bats could ever excavate such cavities, and indeed the remarkable symmetry and the vertical axis of each formation suggests that it is due to solution rather than the activity of bats.

Nevertheless, at least two species of bat at Niah are responsible for erosion of different sorts in the cave. The small *Hipposideros galeritus* (a roundleaf horse-shoe bat) roosts singly and there are certain spots on the cave wall where a bat may be found every day. Here the action of the bats' claws keeps a small area of the surface rough and free from the slimy coating that covers it elsewhere in the deep interior. This roughened patch is often slightly concave, perhaps worn by mechanical erosion.

More positive is the effect of the huge, densely massed colony of *Cheiromeles torquatus* (the naked bat), which occupies a large gallery at one of the highest points of the roof. Fragments of rock quite often fall from this site and are deeply eroded and heavily stained with the bats' excrement. Presumably chemical action weakens the limestone until it breaks under its own weight or under the burden of a *Cheiromeles*, which weighs about six ounces.

Examination of the bat-remains recovered at mid-palæolithic levels in the 1958 Niah dig prove the presence of both *H. galeritus* and *Cheiromeles* at levels corresponding to an age of well over 40,000 years[4], as well as other bats no longer found in the cave[5]; so that, if occupation has been continuous, both these species have had plenty of time to leave their mark.

Galeal Structure in Adult Mosquitoes

IN a previous communication[1], studies of the finer structure of the galeæ in adult mosquitoes were reported. It was pointed out that the galea formed the functional maxilla and typically consisted of a strengthening chitinous rod with a fine outer lamella the tip of which carried a number of variously shaped teeth. Further studies, ranging over eight genera of mosquitoes of the Ethiopian region, have revealed that although there is a variety of morphological types, a progressive reduction in the outer lamella is evident. It should be noted that generic and specific differences in the mouth parts of adult mosquitoes have only been poorly investigated[2], and early studies described only general morphological differences in the trophi, usually of species of known medical and veterinary importance[3-5]. In the present studies, freshly killed mosquitoes were used whenever possible and the heads were soaked in 5 per cent potassium hydroxide for 48 hr. After this they were transferred to a slide, the trophi teased apart with a fine steel point and mounted in polyvinyl alcohol. General examination was carried out at ×100 and detailed examination at ×450.

It has been found that there are four main types of galeal structure which are shown diagrammatically in Fig. 1. Type *A* has a well-developed outer lamella with the distal portion expanded and typically small teeth without pointed tips. Type *B*, which has a simple blade-like appearance, is the commonest form found and the teeth are subject to wide variation in both form and number although the greater proportion are elongate with pointed tips which extend beyond the outer margin of the lamella. Type *C* has the terminal region of the lamella reduced, but this is

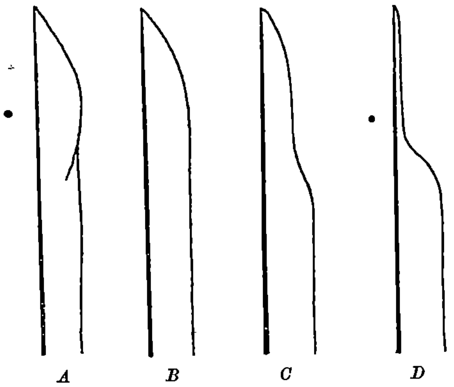

Fig. 1. Diagrammatic representations of the four types of galeal structure as described in the text, showing the progressive reduction of the terminal region of the outer lamella. The teeth typically carried on the lamella are not shown

never less than half the width of the main portion of the lamella. The teeth vary in size and form, but most project beyond the margin of the lamella. Type *D* has the terminal part of the lamella further reduced and in all observed cases this was less than half the width of the main portion. In the majority of cases the teeth were seen to project beyond the margin of the lamella. The species possessing these four types of galeal structure are shown in Table 1.

Table 1. SPECIES POSSESSING THE TYPES OF GALEAL STRUCTURE AS DESCRIBED AND FIGURED

Type *A*: *Uranotaenia balfouri*, *U. annulata*, *Aedes simpsoni*.

Type *B*: *Anopheles gambiae*, *A. demicolus*. *Hodgesia nigeriae*, *Uranotaenia bilineata*, *Mansonia metallicus*, *M. annetti*, *M. africanus*, *M. uniformis*, *Eretmapodites semisimplices*, *Aedes longipalpis*, *A. apicoargenteus*, *A. stokesi*, *A. simulans*, *A. dendrophilus*, *A. irritans*, *Culex horridus*, *C. fatigans*, *C. decens*, *C. annulioris*, *C. cinerellus*.

Type *C*: *Anopheles coustani*, *A. rufipes*, *A. pharoensis*, *Uranotaenia ornata*, *U. philonuxia*, *U. caliginosa*, *Aedes aegypti*, *A. africanus*, *A. pseudoafricanus*, *A. luteocephalus*, *Culex duttoni*.

Type *D*: *Ficalbia hispida*, *Eretmapodites chrysogaster*, *Aedes circumluteolus*, *A. argenteoventralis*, *Culex tigripes*, *C. albiventris*, *C. nebulosus*.

It is difficult at this stage to establish any satisfactory relationship between the galeal structure and the feeding habits of the species. The genus best represented in this study, *Aedes* Mg., possesses each type of galea but nearly all the species represented are known to be anthropophilic in some degree. It must not be overlooked, however, that genera do exist which are capable of biting but have not been observed to do so, while most species take blood for the purpose of ovarian maturation[6]. Thus it would seem that there exists a series of galeal forms represented by the successive reduction of the terminal region of the outer lamella which is not related to feeding method. In the previous communication already mentioned particular attention was paid to the finer structure of the outer lamella and in these present studies further observations have been made upon it. In the great majority of species examined the outer lamella has been seen to have a particulate nature, the individual portions being at right angles to the chitinous rod or directed slightly posteriorly. Early workers[7] stated that this lamella was divided into separate areas by transverse lines which in some cases produced indentations of the outer edge, while it has also been recorded that this structure was essentially membranous with only fine and sometimes anastomosing striations. The present observations tend to support the former view, although the particulate nature was noticeably absent in most *Aedimorphus* species.

Finally, mention must be made of the teeth attached to the galeal lamella. The maxillary index (the average number of teeth on the two maxillæ) has been shown to be related to the power to infect in anopheline mosquitoes[9] and has also been used for demonstrating different races in mosquitoes of the same species but bred from different habitats[10,11]. On the other hand, it was also established that the maxillary index of adults bred from the same egg batch was subject to a wide variation[12]. In the present studies the variations in the number of teeth is considerable, but due to insufficient data concerning feeding habits it is not possible at this stage to construct any well-defined relationship between this activity and maxillary index.

Antimicrobial Substances from Resistant and Non-resistant Seeds

WHY certain plant varieties are resistant to plant pathogenic micro-organisms while others are not resistant is not understood. It is possible that resistant plants produce more antibacterial and antifungal substances than non-resistant plants in order to protect themselves against microbial invasion. This idea was advanced by Irving, Fontaine and Doolittle[1] and was tested by Little and Grubaugh[2]. The latter investigators used the expressed juices of several resistant and non-resistant common garden plants and tested them against both plant and animal pathogenic micro-organisms. They concluded that no distinction could be drawn between the activities of the juices of resistant and non-resistant plants. Similar results were reported by Tims[3]. It was thought advisable to investigate seeds in an attempt to demonstrate any difference between resistant and non-resistant plants. Furthermore, the solvents used in the preparation of seed extracts was not only water but also di-ethyl ether, acetone, ethyl alcohol (95 per cent) and *n*-butyl alcohol. The use of organic solvents for removing antimicrobial substances from plants is the more common procedure[4,5].

The media used for growing the bacteria was a nutrient agar and broth, while the fungi were cultivated in Sabauraud's dextrose agar and broth. The following seven test organisms were employed: *Serratia marcescens*, *Escherichia coli*, *Staphylococcus aureus*, *Mycobacterium smegmatis*, *Candida albicans*, *Erwinia caratovora*, and *Streptomyces venezuelae*. Five additional plant pathogenic micro-organisms were also tested against some of the seed extracts. All bacterial cultures were incubated at 37° C. for 24 hr.

* Jersey Queen and Detroit are resistant, Danish Ball Head and Penn State Ball Head are non-resistant seeds. 0 signifies zone of inhibition absent. All zones are from disk edge to zone edge.

except *S. venezuelae* (24-hr. incubation at room temperature), *E. caratovora* and *Pseudomonas phaseolicola* (48-hr. incubation at room temperature). All the fungi were incubated at 37° C. for 3 days except the following plant pathogens which were incubated at room temperature : *Helminthosporium victoriae* strain 1 and strain 6 (4-day incubation) ; *Ustilage avenae* strain 38–1, strain 38–2, strain 38–3 (7-day incubation) ; *Colletotrichum lindemuthianum* (7-day incubation) ; and *Fusarium oxysporum* f. *conglutinans* (2-day incubation).

Extracts of all seeds were prepared as follows. 20 gm. of the dry seeds were added to 50 ml. of solvent and allowed to soak for 1 hr. The material was next macerated in a Waring blendor for 2 min., then filtered. The aqueous extracts were passed through a Seitz filter. Filter-paper disks (6·35 mm. diam.) were saturated with each extract and allowed to dry in air. The procedure was repeated so that each disk contained four applications of extract. The filter-paper disk method[6] was used for determining the presence of antimicrobial activity. In this method 1 ml. of microbial broth culture was added to approximately 10 ml. of melted agar in sterile Petri dishes and allowed to solidify. The prepared disks were then placed on the surface of the seeded agar and incubated. Measurements of zones of inhibition surrounding the disks were recorded with a millimetre ruler and an illuminated Quebec colony counter. All experiments were conducted six times.

The following varieties of bush bean (*Phaseola vulgaris*) were found to possess no activity against the seven test organisms or against *C. lindemuthianum* and *P. phaseolicola* : Contender (resistant), Tender Long (resistant), and Black Valentine (non-resistant). Pinto Bean III (resistant) and Pinto Bean Tenderpod (non-resistant) were found to exhibit the same negative results. Extracts prepared from the following varieties of oat (*Avena sativa*) : Navarro (resistant), LMHJA (resistant) and Tama (non-resistant) showed no activity against the seven test organisms or on *H. victoriae* strain 1 and 6, *U. avenae* strains 38–1, 38–2 and 38–3. Of the extracts prepared from different varieties of cantaloupe seeds (*Cucumis melo*), di-ethyl ether extracts of Delicious (resistant) and Honey Rock (non-resistant) showed slight activity on two of the seven test organisms. However, cantaloupe Honey Ball Pink Flesh (non-resistant) and cantaloupe No. 5 Powdery Mildew (resistant) showed no activity against all seven test organisms. Results with extracts from cabbage seeds (*Brassica oleracea* var. *capitata*) listed in Table 1 indicate that resistant cabbage seeds possess greater amounts of antimicrobial substances than do non-resistant seeds.

The antimicrobial substance present in cabbage plants is known as rapine[7]. It may be this organic polysulphide[8] that is present in greater amounts in resistant cabbage seeds than in the non-resistant variety. Failure to obtain any antimicrobial activity from other resistant seeds studied in this investigation cannot be explained. Perhaps the antimicrobial substances are liberated during seed germination. Studies in this field are now in progress.

We wish to thank Dr. J. S. Tidd (Asgrow Seed Growers Inc., Connecticut) for his generous supply of seeds ; Dr. L. L. Dean (University of Idaho) for bean varieties ; Dr. H. C. Murphy (Iowa State College) for oat varieties ; Dr. H. H. Luke (University of Florida) for cultures of *Helminthosporium victoriae* ; Dr. W. J. Zaumeyer (U.S. Department of Agriculture) for *Colletotrichum lindemuthianum* ; and Dr. C. S. Holton (University of Washington) for cultures of *Ustilago avenae*.

Oxygen Deficiency and Radiation Damage in the Insect *Rhodnius*

REDUCTION in radiation damage under conditions of low oxygen tension during the exposure has been demonstrated in a number of plant and animal tissues[1]. This report deals with similar effects in the insect *Rhodnius prolixus*. Latent radiation damage in 'resting' cells of the epidermis of *Rhodnius* is expressed as a burn at delayed moulting following a blood meal[2]. In these studies, the delay in moulting and the size of the burns have been utilized as convenient indices of the oxygen effect during X-irradiation.

Unfed 4th instar nymphs were irradiated on the dorsal surface of the abdomen through a hole, 1·6 mm. diam., drilled in a lead shield 5 cm. in thickness[2]. During exposure (at 16 cm. from the target of a 2 MeV. X-ray machine ; dose-rate 6,000 r. per min. as measured in air without the shield) the insects were enclosed in a small chamber through which either air or nitrogen was circulated at a rate of 3 litres per min., after bubbling through water at room temperature. *Rhodnius* can be held in nitrogen for periods of 45 min. without injury ; however, the insects are completely immobilized after 1½ min. The nymphs were held in either air or nitrogen for 10 min. prior to irradiation. After exposure they were fed and returned to an incubator at a constant temperature of 25° C. and a relative humidity of 75 per cent.

Throughout the dose-range employed in these experiments, and for both criteria of damage, the effect inflicted by irradiation in air was two to three times that produced when the same dose was delivered in nitrogen (Fig. 1). The delay in moulting following irradiation at the lowest dose in nitrogen was barely perceptible (controls moult in 14 days), but was large after an equal dose in air. Burns did not develop after exposure in nitrogen at doses below 120 kr., but they were invariably present with doses as low as 60 kr. in air.

Thus, oxygen deficiency produces a considerable amount of protection from X-irradiation in the epidermal cell layer in *Rhodnius*. As indicated previously, and confirmed by unpublished cytological studies, the delay in moulting is due to mitotic inhibition in the epidermis prior to moulting. The inhibition of division is particularly striking in this organism because the epidermal cells enter division synchronously at a fixed time after a meal of blood. The ratio between the dose in air and the dose in nitrogen that produces equal effects is between 2·5 and 2·6, a value that agrees with those given by Evans *et al.*[3] for mitotic delay.

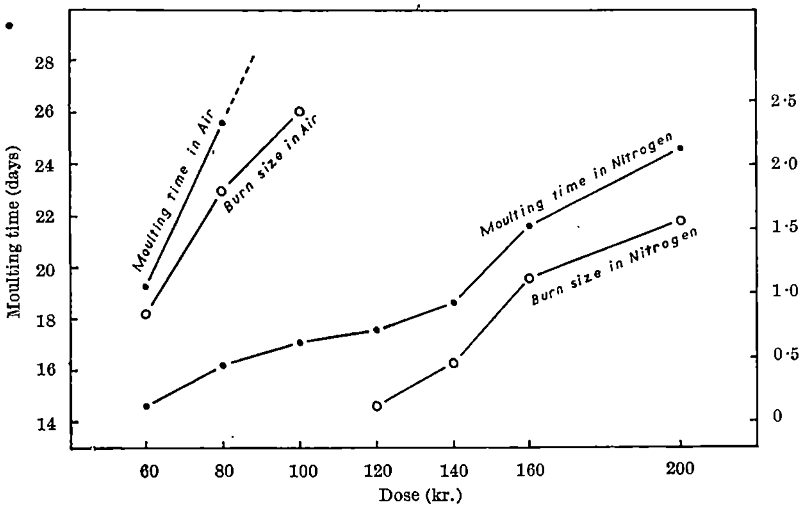

Fig. 1. Moulting times and sizes of burns of 4th instar *Rhodnius* nymphs irradiated in air and in nitrogen. Each point represents the mean from the results with five individuals. Two insects died during ecdysis after exposure to 100 kr. in air (moulting time indicated by dotted line) ; the burns were measured after death. The moulting time after feeding for unirradiated controls under similar conditions of temperature and humidity was 14 days

Further details of these experiments will be published elsewhere.

Effects of Kinetin, Gibberellic Acid and Certain Auxins on the Development of Shoot Buds on the Protonema of *Pohlia nutans*

DURING recent investigations[1] on the effects of light of various wave-lengths on the development of the protonema and the formation of shoot buds in *Pohlia nutans* (Hedw.) Lindb., it was discovered that buds were formed only in light which included the red region of the spectrum. Furthermore, experiments on the supply of various concentrations of sucrose or glucose to the protonema suggested that the effect of red light was not merely a trophic one, but that a specific formative stimulus was probably involved. Since several authors have found that certain of the physiological responses of various flowering plants to kinetin or gibberellic acid are similar to those induced by red light, for example the expansion of leaf tissue and the onset of germination in certain dormant seeds, it seemed that it might be of interest to study the effects of these two physiologically active substances on the development of the protonema and the initiation of shoot buds in *Pohlia nutans*.

Aseptic cultures were prepared from small protonema inocula on a standard Knop's agar, with addition of various concentrations of kinetin, kinetin + 0·1 mgm./l. indoleacetic acid, gibberellic acid and, for comparison, 0·1 mgm./l. indoleacetic acid. The cultures were grown under artificial light from fluorescent tubes ('Natural') giving 375 foot candles at the level of the cultures. The temperature was regulated at 22–24° C. Another series of cultures was grown with addition of vari-

ous concentrations of the three auxins : indoleacetic acid, naphthaleneacetic acid, and indoleacetonitrile. The results obtained with the first series of cultures are summarized in Table 1.

It will be seen from Table 1 that all the concentrations of kinetin supplied, whether with or without the addition of indoleacetic acid, resulted in the early appearance of a large number of shoot buds on the protonema ; in fact, the number formed was so great that it was both impracticable and unnecessary to carry out counts of shoot buds for comparison with bud formation on the other protonema cultures. With gibberellic acid there was a similar stimulation of bud formation at the highest concentration used (100 mgm./l.), but the three lower concentrations had relatively little effect. Neither gibberellic acid nor kinetin had any great effect on the growth of the protonema. With the three auxins tested, there was complete inhibition of bud formation in naphthaleneacetic acid at all three concentrations, 0·1, 1·0 and 10 mgm./l., in indoleacetic acid at 10 mgm./l. and in indoleacetonitrile at 50 mgm./l. A reduced number of buds was produced in indoleacetonitrile at 1 mgm./l. and at 10 mgm./l. The inhibition of bud formation in indoleacetic acid and naphthaleneacetic acid is in agreement with results obtained by previous workers[2,3]. Indoleacetonitrile had apparently not been tested previously.

The results with kinetin and gibberellic acid are of interest in that not only is the number of buds increased but also the date of their first appearance advanced as compared with the control cultures. Gorton and Eakin[4] similarly observed that kinetin increased the number of shoot buds on the protonema of *Tortella caespitosa*, but in contrast with the results reported here, they failed to obtain any earlier appearance of the buds in the presence of kinetin. We are not aware of any previous study of the effects of gibberellic acid on the development of buds on moss protonemata, although its action on the growth of the protonema has been followed in *Splachnum ampullaceum*[5].

It may be concluded from the present work that kinetin and gibberellic acid can both stimulate the formation of buds on the protonema of *Pohlia nutans*, and in this respect are similar in action to red light. It remains to be seen, however, whether these substances can promote the development of buds on a protonema which has been maintained throughout its growth in complete darkness.

We are indebted to Prof. E. Boyland, Chester Beatty Research Institute, for the supply of kinetin, and to Dr. P. W. Brian, Akers Research Laboratories, for the gibberellic acid.

CYTOLOGY

Some Effects of Colchicine on Lampbrush Chromosomes

ISOLATED lampbrush chromosomes from the oocytes of many vertebrates have been subjected to various treatments to obtain information about the basic structure and organization of chromosomes. Lampbrush chromosomes are ideally suited for studies of this kind for they are long (350–850μ), easily isolated and can be treated without fixation and viewed immediately with an inverted phase microscope system[1,2]. This enables the experimenter to observe the action of the reagents upon the chromosomes soon after treatment and with minimum handling.

Solutions of pepsin, trypsin, ribonuclease and deoxyribonuclease have been applied to lampbrush chromosomes. Where the first three reagents destroy the material coating the lateral loops without destroying the linear integrity of the chromosomes, deoxyribonuclease effects a fragmentation of the lateral loops and of the axis of the chromosomes to which the loops are attached. Gall[3] has shown by electron microscopy that although the coating surrounding the loops is destroyed by pepsin, the loop axis remains integral and attached to the axis of the chromosome from which it originates. Callan and MacGregor[4] have demonstrated for the first time that deoxyribonuclease induces a fragmentation of the loop axis and chromosome axis, which is conclusive evidence that deoxyribonucleic acid exists not only in the main axis of the chromosome but also in the lateral loops.

Colchicine has long been known as a spindle inhibitor and mitotic poison. We have found that colchicine elicits a change in the morphology of lampbrush chromosomes in *Triturus viridescens*.

The chromosomes were isolated in a 0·59 per cent sodium chloride solution from nuclei of oocytes. The colchicine was dissolved in the same saline used for isolating the chromosomes. Colchicine was found to be effective at a concentration of 50 mgm./cm.³. Controls were run using the saline solution only. The preparations were then examined in an unfixed condition in specially constructed slides using an inverted phase-contrast microscope as proposed by

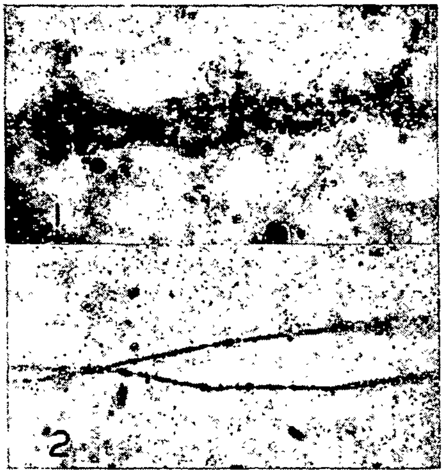

Fig. 1. Portion of an untreated bivalent fixed and stained with iron-alum hæmatoxylin showing intact loops. Fig. 2. Portion of a colchicine-treated bivalent fixed and stained with iron-alum hæmatoxylin. (× 1,000)

Gall[1]. Similar colchicine-treated and control preparations were made and fixed in formaldehyde vapour for 15 min. After fixation the slides were placed in 5 per cent formalin for 2–3 min. and stained with aceto-orcein or iron-alum hæmatoxylin. They were then placed in absolute alcohol to remove the excess stain, and the depression was filled with immersion oil and a coverslip applied to render the preparations permanent. These slides were compared with the unfixed preparations examined with the phase-contrast microscope. In both cases the results were identical.

It was found that while colchicine caused no disruption in the linear integrity of the chromosomes, there was a complete absence of loops along the entire length of the chromosomes (Figs. 2 and 4) except for the giant loops which remained. The control slides showed no absence of lateral loops (Figs. 1 and 3). Chromomeres extend along the entire axis of normal lampbrush chromosomes and render the axis cylinder of uneven diameter. In the chromosomes treated with colchicine it was noted that the axis is more uniform in diameter than in the controls and that the chromomeres are closer to one another than normally. This may be caused by a contraction of the chromosome following colchicine treatment. Most of the early experimenters with colchicine thought that the extra contraction of the chromosomes following treatment with the alkaloid drug resulted from the absence of a functioning spindle and was not an effect of a direct action on the chromosomes. However, Ostergren[5] claimed that since the extra chromosome contraction is present in prophase nuclei, it cannot be entirely due to a suppressed spindle or prolonged metaphase. This seems to be also the situation with the colchicine-treated lampbrush chromosomes for they are prophase chromosomes (diplotene).

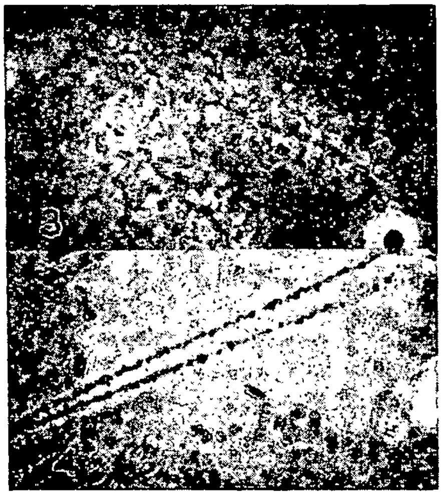

Fig. 3. Phase-contrast photograph of untreated bivalent (unfixed). Note presence of lateral loops. Fig. 4. Phase-contrast photograph of bivalent after colchicine treatment (unfixed). Note absence of lateral loops and intact axis. (× 1,000)

There are two pieces of evidence indicating that the main axis of the loop is not destroyed either along its length or at its point of origin with the axis of the chromosome. Since the interchromomeric connexions on the axis of the chromosome are not disrupted following treatment with colchicine and since there is an apparent contraction of the chromosome, it would seem that the loop axes must also contract, for they are continuous with the interchromomeric strands[3]. Also, while the loops are absent after treatment, the giant loops, when observed, are always attached to their point of origin although they do not show their usual extension into the saline; rather they appear to be drawn closer to the axis of the chromosome.

Induction of Structural Chromosome Changes by Visible Light

It has been known since the beginning of this century that visible light is able to induce inhibitory and lethal effects on living organisms when oxygen and some sensitizing substance (which absorbs the light) are present. This phenomenon has been called 'photodynamic action'. The biological effects are believed to be due mainly to a photosensitized oxidation of organic material[1]. The fact that mutations can be induced photodynamically in micro-organisms has been shown by Döring[2] and Kaplan[3–5]. Previous studies have failed to demonstrate the production of structural changes in chromosomes among the effects induced in plant root-tips by visible light in the presence of some sensitizing substance[6,7]. The dyes used in these studies, eosin and neutral red, have no particular affinity for the cell nucleus. It seems reasonable to assume that in order to induce changes in the genetic material the light has to be absorbed by dye molecules present inside the cell nucleus. Therefore, acridine orange, which, like a number of other acridine derivatives, has a high affinity for nucleic acids[8,9], was chosen as the sensitizing substance in the present study of the effect of visible light on chromosome structure in the root-tip cells of the broad bean, *Vicia faba*.

Table 1. THE FREQUENCIES OF CHROMOSOMAL ABERRATIONS PRODUCED AT VARIOUS OXYGEN TENSIONS BY VISIBLE LIGHT IN BEAN ROOT TIPS PRETREATED WITH ACRIDINE ORANGE. ROOTS ILLUMINATED FROM ONE SIDE ONLY. *p*H OF *M*/150 BUFFER SOLUTION = 5·8

Duration of illumination (min.)	Pretreatment with acridine orange (+ or −)	Concentration of oxygen in the gas phase (per cent)	Number of metaphases analysed	Abnormal metaphases (per cent)	Aberrations/100 cells		
					I Isolocus breaks	II Exchanges	I + II
90	−	100	100	0	0	0	0
0	+	100	100	1	1	0	1
45	+	0	100	0	0	0	0
45	+	1	100	1	1	0	1
45	+	20	100	3	4	0	4
45	+	100	300	17	19	5	24
60	+	100	100	28	32	8	40

In the absence of light, concentrations of acridine orange less than 10^{-5} *M* proved to be non-toxic to the roots. In the presence of light, a strong toxic effect was obtained by concentrations of acridine orange greater than 10^{-6} *M*. This toxic effect was to a large extent eliminated by the experimental procedure finally adopted. When the bean seedlings had developed lateral roots, 0·3–1 cm. long, they were transferred to solutions of acridine orange made up of 3·5–5 × 10^{-6} *M*/l. acridine orange in tap water. In these solutions, the seedlings were allowed to grow in the absence of light for about 20 hr. Before the seedlings were exposed to light, excess dye was washed out by keeping the roots immersed in tap water for 2–3 hr. During the illumination period, the seedlings were in 'Lucite' vessels with their roots immersed in *M*/150 phosphate buffer solutions. The 'Lucite' vessels were the same as those which had been used previously in X-ray experiments. They have been described in detail elsewhere[10]. The different gas mixtures were introduced into the vessels through fritted glass filters. Oxygen-free nitrogen was obtained by passing tank nitrogen (containing 0·06 per cent oxygen) over active copper in a Meyer–Ronge column[11]. When the roots were exposed to light in the presence of a respiratory inhibitor, the seedlings were kept under anaerobic conditions for 10 min. before an oxygen-free solution of the inhibitor was introduced into the vessel. During the treatment, the desired gas or gas mixture was bubbled through the solution. The light sources were Philips 'Attralux' lamps, type 13378*E*/44, 24 V., 150 W. To prevent a marked rise of the temperature of the solution surrounding the roots, the 'Lucite' vessels were immersed in running tap water during the period of illumination. Between the source of light and the roots were 2·5 cm. air, 0·2 cm. glass, 13·5 cm. water and 1 cm. 'Lucite'. When the seedlings were illuminated from one side only, the temperature of the solution inside the 'Lucite' vessels was stable at 15° C.; when the seedlings were illuminated from two sides, the temperature varied between 15 and 18° C. In most experiments the seedings were kept, after the illumination, with their roots immersed in tap water at 20° C. in the absence of light for 22 hr. Before fixation, the roots were treated with 0·05 per cent colchicine for 4 hr. at 20° C. in the dark. The roots were fixed in alcohol–acetic acid, 3 : 1, and the slides prepared as permanent Feulgen-squashes.

Table 1 shows that structural chromosome changes can be produced by visible light in root-tips pretreated with acridine orange. However, a marked effect is obtained only when the gas bubbled through the solution contains more than 20 per cent oxygen. In the absence of either acridine orange or light, no significant effect is produced. Other experiments have shown that no aberrations seem to appear during the first 10 hr. after the treatment. In that respect, the photodynamically induced aberrations are similar to those induced by radiomimetic chemicals such as di-(2.3-epoxypropyl)ether[12], potassium cyanide[13], and tert. butylhydroperoxide[14]. In contrast to the radiomimetic chemicals mentioned, X-rays seem to be most effective in cells which enter mitosis within 8 hr. after the irradiation[12].

The induction of structural chromosome changes by visible light requires the presence of both oxygen and a sensitizing substance and appears, thus, to be a typical photodynamic effect. As a result of a photosensitized oxidation, organic peroxides may be formed.

Table 2. THE EFFECT OF 'CUPFERRON' ON THE FREQUENCIES OF CHROMOSOMAL ABERRATIONS PRODUCED BY VISIBLE LIGHT IN BEAN ROOT-TIPS IN THE PRESENCE OF ACRIDINE ORANGE. Schenck[15,16] has reported light-induced *in vitro* synthesis of a considerable number of different organic peroxides in the presence of oxygen and some sensitizing substance. Since organic peroxides are known to produce chromosomal aberrations in bean roots[13,17], it seems possible that such compounds are involved in the photodynamic induction of structural chromosome changes.

A radiomimetic effect of acridine orange has been reported by D'Amato[18], working with onion root-tips as experimental material. Since D'Amato performed his experiments "in the ordinary conditions of diurnal illumination", it seems possible that in his experiments, too, the radiomimetic effect of acridine orange was due to its ability to act as a photosensitizing substance. In the present study, acridine orange was inactive in the absence of light.

Because of the respiratory activity of the cells, the oxygen concentration is likely to be considerably lower in the central parts of an organized tissue such as a bean root than in the solution surrounding the tissue. The existence of such an oxygen gradient in respiring tissues explains why the X-ray sensitivity of bean roots is influenced by much lower concentrations of oxygen in the presence, than in the absence, of a respiratory inhibitor[10,19].

In order to find out if structural changes in chromosomes can be induced photodynamically at lower oxygen concentrations when respiration is inhibited, a number of experiments were performed with cupferron (the ammonium salt of N-nitroso phenylhydroxylamine) as a respiratory inhibitor. The results appear in Table 2. In the 45-min. experiments, the cupferron treatments were of the same duration as the period of illumination. When the roots were illuminated for 30 min. only, the duration of the cupferron treatments was 40 min. Previous experiments have shown that cupferron is a radiomimetic agent in the presence of oxygen[13,20]. However, in order to obtain a marked radiomimetic effect, it is necessary to have higher concentrations of cupferron and higher treatment temperatures as well as longer periods of treatment than those used in the present study (400 μM; 15–18° C.; 40–45 min.).

Table 2 shows that in the absence of either light or oxygen there is no marked effect of cupferron on roots which have not been pre-treated with acridine orange (IV*b*, V*c*). There is some evidence that the radiomimetic effect of cupferron in the presence of oxygen is somewhat increased by light (V*a* and unpublished results). In the absence of light, no marked effect is obtained with cupferron on roots pre-treated with acridine orange (II*b*, IV*c*, V*d*). However, when roots pre-treated with acridine orange were illuminated in the presence of cupferron but in the absence of oxygen (oxygen-free nitrogen bubbled through the solution), the magnitude of the effect obtained was of the same order as that produced by 100 r. of X-rays in air, which is close to the upper limit of what can be conveniently scored (I*a*, II*a*, III*a*, IV*d*). When oxygen was introduced into the system the effect decreased. At 1 per cent oxygen in the gas phase, the effect was still about the same as that obtained in the absence of oxygen (I*b*, IV*e*), but when the oxygen concentration was 20 per cent or more, the effect was no stronger than that obtained in the absence of cupferron (Table 1, Table 2 : I*c*, I*d*).

The fact that the highest frequency of aberrations was obtained when oxygen-free nitrogen is bubbled through the solution suggests that in the presence of cupferron there is some other mechanism than that involving oxygen by which light energy absorbed by acridine orange can be used for the production of chromosomal aberrations. This would mean that, in contrast to the results summarized in Table 1, those obtained in the cupferron experiments are not explainable by the peroxide hypothesis.

The investigation was supported by a grant from the Swedish Natural Science Research Council.

ANIMAL PHYSIOLOGY

Hyperglobulinæmic Thrombo-Hæmorrhagic Diathesis

In reviewing the literature of the hyperglobulinæmias one is struck by the frequency of the reports of a concomitant hæmorrhagic diathesis. In a survey by us of more than a thousand cases of macroglobulinæmia, cryoglobulinæmia, visceral leishmaniasis and miscellaneous hyperglobulinæmias, a hæmorrhagic diathesis was reported in 63–94 per cent of the cases in each category. These observations suggest that purpura is a general phenomenon in the presence of increased plasma globulins.

Thromboses, in addition to hæmorrhages, were reported in 3–21 per cent of the cases. This coincidence of thromboses and hæmorrhages is of sufficient moment to warrant its consideration as a clinical entity for which the name hyperglobulinæmic thrombo-hæmorrhatic diathesis is suggested. We have also observed both thromboses and hæmorrhages in a group of patients reported elsewhere[1,2].

An explanation of this observation is suggested by the experimental studies made in this laboratory which have shown that some globulins have the ability to combine with clotting factors. The hypothesis is proposed that in a variety of clinical conditions γ-globulins are produced which acquire the ability to combine with clotting factors. When such associations occur, the clotting factors are withdrawn from active participation in clotting and hæmorrhages ensue. When such combinations dissociate, large amounts of clotting factors are released suddenly into the blood-stream and the situation becomes thrombotic. When both association and dissociation are occurring, the clinical picture would include both hæmorrhages and thromboses, that is, a thrombo-hæmorrhagic diathesis.

8 patients with euglobulin have been studied; 2 with macroglobulinæmia, 2 with multiple myeloma, 1 with alcoholic liver cirrhosis, 1 with rheumatoid arthritis and 2 with myocardial infarctions. One of the myeloma cases had a cryo-fibrinogen-globulin complex as well as the euglobulin.

The following behaviour characteristics of the unusual euglobulins studied are significant.

(1) These proteins have the ability to complex with, and co-precipitate, clotting factors. Precipitation of the euglobulin from the patient's plasma, or from normal plasma to which it was added, reduced the concentration of clotting factors remaining in the plasma. These clotting factors were demonstrable in the solution of the precipitated euglobulin.

(2) The euglobulins can combine with and remove from the plasma active accelerin, its precursor proaccelerin, prothrombin and convertin. The amounts and proportions of the clotting factors involved vary from case to case.

(3) Some results suggest that this association of euglobulin with clotting factors occurs *in vivo* as well as on precipitation of the euglobulin. It was frequently observed that the sums of the accelerin and proaccelerin concentrations in the solution of the euglobulin and in the plasma freed of euglobulin were greater than the concentrations in the whole plasma. This phenomenon was also seen when precipitation of the euglobulin did not reduce the plasma accelerin- or proaccelerin-level, but when appreciable amounts of these factors were found in the euglobulin. In one case, a high level of prothrombin activity was demonstrable in the euglobulin precipitated from serum when the residual serum prothrombin was nil. In another case, more accelerin, proaccelerin and convertin were measurable in serum euglobulin and euglobulin-free serum than in the whole serum. The clotting factors present in excess of the measurable plasma- or serum-levels represent the amount which was held *in vivo* by the euglobulin.

(4) The possibility of *in vivo* inhibition of clotting factors by euglobulin has been suggested by instances of increased prothrombin, convertin and proaccelerin after the removal of euglobulin.

The clotting abnormalities are usually, but not always, associated with increased total plasma proteins. 2 of the 8 patients studied had normal total protein-levels; all but one had increased γ-globulins. Comparison of the quantities of euglobulin present with the amount of clotting factor activity coprecipitated indicates that euglobulin of the order of 100 mgm. per cent can contain as much as 600 per cent of proaccelerin.

A globulin which complexed with fibrinogen to form a cold precipitable complex was first reported in one of these cases of multiple myeloma[1]. This observation has been confirmed by Firkin[3] in a case of essential cryoglobulinæmia. On the basis of the concept presented here, dicumarol was used by Domz and Feigin[4] in a case of essential cryoglobulinæmia with Raynaud's phenomenon, cyanosis and necrosis of the fingers. There was an immediate response to the therapy with complete relief of the pain within 48 hr., followed by rapid healing of the fingers.

Recurrent Inhibition in Cerebral Cortex

RECURRENT inhibition via interneurones (Renshaw cells) was recently invoked by Brooks and Wilson[1] to account for changes in monosynaptic spinal reflexes following antidromic activation. This mechanism, which confines stretch reflexes to their paths of afferent origin, operates through a cholinergic synapse between the motoneurone axon collateral and the Renshaw cell[2], which liberates an unknown inhibitory transmitter. Presumably the same mechanism functions with respect to disynaptic pathways through the cord. The purpose of this communication is to describe an analogous system in the cerebral cortex of dogs, operated under ether and immobilized by succinylcholine.

During experiments on the interaction between antidromic volleys in the medullary pyramids[3] recorded with cortical microelectrodes, and impulses from the thalamic nucleus ventralis lateralis[4], antidromic inhibition of cortical re-excitation[5] and directly excited cortical activity were noted[6]. In the present experiments the pathway from the thalamus to the corticospinal tract via the cortical projection of the nucleus ventralis anterior was used as a test. This has been presumed to be disynaptic with one interposed neurone. The antidromic volley was delivered via one bundle of corticospinal fibres, separated from the pyramid. The ventralis anterior was stimulated bipolarly, and the responses recorded in the remainder of the medullary pyramid (Fig. 1, *A* and *B*). It was found that the anticholinergic drug, dihydro-beta-erythroidine hydrobromide, reduced the magnitude of antidromically elicited inhibition in this 3-neurone arc. The drug was given in the ipsilateral carotid artery in amounts of 0·5 mgm./kgm. following isolation of the internal carotid circulation. Antidromic inhibition, as judged both by the decreased rate of discharge in the corticospinal tract to pyramidal stimuli of increasing frequency and by the amount of hyperpolarization of cortical neurones recorded with intracellular electrodes[3], was increased by 20–30 μgm. of acetylcholine chloride, and increased still further by 0·2–0·5 mgm./kgm. of eserine sulphate, given intra-arterially (Fig. 1, *C*). With increasing frequency of stimulation of the medullary pyramid the probability of firing of single gigantopyramidal neurones dropped, according to a parabolic function, over the frequency-range of 30–40 c./s. The same effect was obtained from bipolar stimulation of the cortex at a depth of 1·0–1·3 mm.

Further, the inflexion in the rising phase of intracellular pyramidal neurone spikes was increased by antidromic and deep cortical stimulation. This represents hyperpolarization.

Since the Renshaw mechanism in the cortex cannot be substantiated without physiological demonstration of the inhibitory interneurones, the cortical layers were systematically mapped during the above-mentioned pyramidal hyperpolarization of cells. Rapidly discharging units were found at depths corresponding to cortical layers III and IV in the dog 'motor' and 'premotor' areas (Fig. 1, *D*). These units were active during hyperpolarization of primary neurones. Further pharmacological studies showed that the hypothetical inhibitory synapse was blocked by picrotoxin, strychnine and tetanus toxin, the latter two drugs having been used in the spinal cord by Eccles with similar results[2]. A detailed description of this and related findings is in preparation.

Histological evidence for a cortical Renshaw system was also sought. Cajal demonstrated the endings of pyramidal neurone collaterals on short-axon neurones, and functional evidence for their existence is abundant[5]. The existence of star-cell axons (assumed to be interneurones) upon the apical dendrite of pyramidal cells in the same or next lower layer has also been shown (Fig. 2, *A*). Recent work[7] has indicated that much, if not all, of the activity at axo-dendritic synapses relates to the creation of long-standing hyper- or de-polarization of the apical dendrites. It has also been suggested[8] that such changes are due to the activity of excitatory or inhibitory interneurones, although no physiological or anatomical arrangement of these has been put forth which would account accurately for most of the results concerning cortical activity.

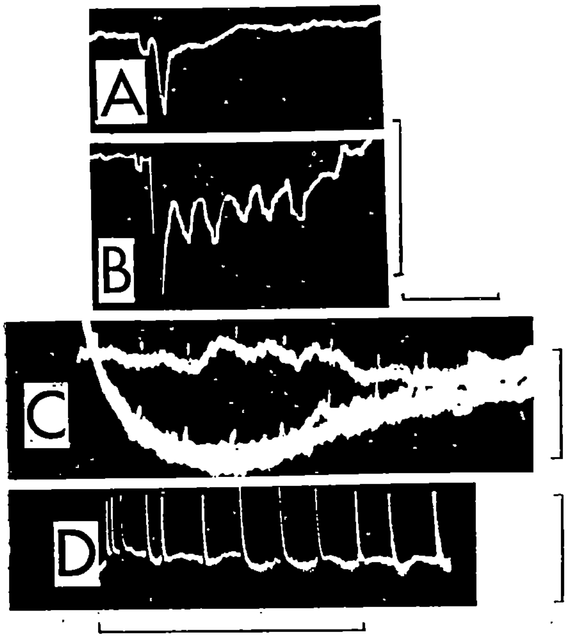

Fig. 1. *A*, Response recorded in one bundle of medullary pyramid fibres following stimulation of remainder of pyramid and stimulation of the ventralis anterior. *B*, Same response after 0·5 mgm./kgm. dihydro-beta-erythroidine hydrobromide. Note increased amplitude of surface positive and oscillating (interneuronal) responses. For *A* and *B* time mark is 8 msec. *C*, Potentials generated in a gigantopyramidal neurone (responding to pyramidal stimulation) by an antidromic volley (40 c./s.) in corticospinal fibres recorded between an intracellular electrode and an indifferent point. Horizontal superposed traces were obtained before antidromic stimulation. Intracellular negativity downward in this and following record. The latency of this hyperpolarization is 0·9–2·0 msec. following activity of cells in deeper layers. Msec. time marks. Potential calibration, 5 mV. *D*, Discharges of a cortical inhibitory interneurone, recorded intracellularly at a depth of 1·1 mm. in dog motor cortex, following antidromic volley in corticospinal tract. Time mark, 20 msec., potential calibration, 30 mV.

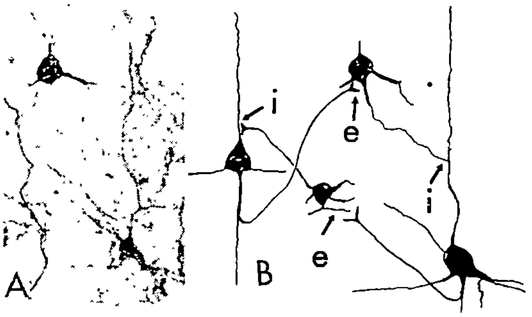

Fig. 2. *A*, Photomicrograph of cat visual cortex (by courtesy of Dr. E. Ramon-Moliner, Montreal Neurological Institute), modified Golgi Cox stain, showing ending of star-cell axon in layer IV upon apical dendrite of pyramidal neurone in layer V. Arrows trace course of axon. (× 125). *B*, postulated anatomical arrangement for a cortical recurrent inhibitory system. Inhibitory endings, *i*; excitatory (cholinergic) endings, *e*

It is not postulated that this inhibitory mechanism, which had been suggested by Phillips[3] and others, is the only, or even the most widely active, means for cortical inhibition. However, these results, in addition to a large number of supporting observations which are less rigorous, make its existence most likely. Its proposed structure and operation are outlined semidiagrammatically in Fig. 2, *B*. Inhibitory endings are thought to exist primarily on neighbouring or remote neurones, rather than on the neurone the collateral of which activates the inhibitory cell. Cells firing to afferent impulses would excite neighbouring cells until the inhibitory mechanism reduced the activity multiplication factor to one. Firing cells inhibit neighbours, and are thereby protected from inhibition. In this manner a small group of cells with inhibitory interconnexions could maintain a relatively constant firing-rate without necessitating reverberation or re-entry circuits, which might nevertheless exist. It is suggested further that the hyperpolarization exerted by inhibitory interneurones has only a partial effect upon, but does not alone control, the basal firing rhythm[6] of primary cortical neurones. Electrocorticographical findings which support this concept have been obtained[9] and a similar arrangement based on theoretical considerations has been independently described by Milner[10].

Synthesis of Dextran Sulphate labelled with Carbon-14 and Tracer Experiments in the Rat

PREVIOUS experiments[1,2] with the heparinoid anticoagulant, dextran sulphate, in experimental animals and man have established that between 40 and 50 per cent of a single intravenous dose of dextran sulphate of a molecular size suitable for clinical use was excreted in the urine in 48 hr.

Autoradiographs of the tissues of animals given dextran sulphate of similar molecular characteristics labelled with sulphur-35 suggested that the portion of the dose unaccounted for by urinary excretion was broken down within the body but that the ^{35}S-sulphate residue was retained in the general body pool of ester sulphate since, as with the administration of $Na_2{}^{35}SO_4$ [3], radioactivity was demonstrable in gastric mucin, skin and, to a lesser extent, in cartilage (Walton, unpublished work). This redistribution of the labelled sulphate residue rendered difficult the interpretation of the results obtained in terms of the distribution of dextran sulphate in the tissues. Accordingly, further experiments have been undertaken using dextran sulphate labelled in the dextran part with carbon-14.

^{14}C-Dextran was prepared by inoculating an aqueous buffered medium containing yeast extract and ^{14}C-sucrose (3·76 gm., 3·3 mc.) with *Leuconostoc mesenteroides* and incubating the mixture for 3 days at 25° C. ^{14}C-Dextran and protein were precipitated with ethanol. The precipitate was redissolved and freed from protein by treatment with trichloracetic acid yielding 1·162 gm. ^{14}C-dextran with a specific radioactivity of 22·39 mc./mole of carbon.

The ^{14}C-dextran so obtained was partially hydrolysed with *N*/1 sulphuric acid and fractionated by the addition of successive increments of acetone. A fraction (232 mgm.) of viscosity comparable to that used for the preparation of clinical dextran sulphate was selected for sulphation by treatment with chlorosulphonic acid in pyridine as previously described[4].

The ^{14}C-dextran sulphate (413 mgm.) (found: C, 20·40; H, 2·15; S, 16·85. $[C_6H_{8\cdot16}O_5\,(SO_3Na)_{1\cdot84}]_n$ requires C, 20·59; H, 2·35; S, 16·86 per cent) had a specific radioactivity of 22·39 mc./mole carbon or 0·45 µc./mgm. and an anticoagulant activity of 13 units/mgm. Paper chromatography revealed results similar to those obtained with the dextran sulphate previously employed[2].

A male albino rat weighing 273 gm. was injected intravenously via the tail-vein with a solution of ^{14}C-dextran sulphate (5 mgm., that is, 2·25 µc. and dose equivalent to 18·3 mgm./kgm./body-weight) in saline and placed immediately in a closed-circuit apparatus[5], allowing collection of the respired air. The rat was maintained thus for 48 hr., being allowed access to food and water *ad libitum*. The expired carbon dioxide was collected in 3 *N* sodium hydroxide and converted into barium carbonate. Aliquots were used for the determination of specific radioactivity.

At the end of the experimental period the animal was killed by a blow on the head, various organs were removed, weighed and portions homogenized by grinding under liquid air. Other portions were submitted to histological examination which confirmed that the injected material, like previously tested examples of dextran sulphate for clinical use[6], was not segregated in reticulo-endothelial cells.

Table 1. LABELLED CARBON CONTENTS OF RESPIRED CARBON DIOXIDE AND OF TISSUES OF RAT FOLLOWING INJECTION OF 5 MGM. (2·25 µC.) OF ^{14}C-DEXTRAN SULPHATE IN EXPERIMENT LASTING 48 HR.

Source	Weight (gm.)	Carbon content (per cent)	Specific radio-activity (µc./mole carbon)	Total radio-activity (µc.)	Concentration of injected radio-activity (per cent)
Carbon dioxide respired	125·674	6·085	0·13	0·08	3·55
Liver	13·366	13·35	1·19	0·18	8·0
Spleen	0·650	9·15	1·00	0·005	0·22
Lungs	2·810	9·08	0·19	0·004	0·18
Kidneys	2·423	23·20	1·68	0·08	3·55
Muscle (sample)	1·120	9·73	0·17	—	—
Total musculature	123·94*	—	—	0·17	7·56
Bone (femur)	0·86	5·62	0·15	—	—
Whole skeleton	14·80*	—	—	0·01	0·44

Total radioactivity accounted for: 23·50 per cent of dose.
* Average figure derived from published data, ref. 10.

^{14}C-Dextran and ^{14}C-dextran sulphate were burned in a stream of oxygen free of carbon dioxide, and aliquot parts of the homogenized tissues were treated with boiling chromic acid combustion fluid[7]. The carbon dioxide produced in each case was converted into barium carbonate and the radioactivity determined by the infinitely thick disk method[7-9] using an end-window counter and a sample of poly-(^{14}C-methyl) methacrylate supplied by the Radiochemical Centre, Amersham, as a standard source for barium ^{14}C-carbonate. The results tabulated are corrected for background and paralysis time of the counting equipment.

Excretion of carbon dioxide labelled with carbon-14 in the expired air indicated complete oxidation of a portion of the administered ^{14}C-dextran sulphate. The rate at which this occurred appeared to be somewhat slower than the rate of excretion of labelled carbon dioxide from ^{14}C-dextran in rats since 3·55 per cent of the injected dose of ^{14}C-dextran sulphate was accounted for after 48 hr. in the present experiment as compared with 8–10 per cent of ^{14}C-dextran[11] in the same period. The radioactivity of the expired air together with that found in the organs examined accounted for 23·50 per cent of the dose administered. Assuming urinary excretion of a further 40–50 per cent in the first 48 hr. as previously found[1,2] about 30 per cent remained unaccounted for and presumably was distributed in the body fluids and tissues not sampled.

The distribution of radioactivity in the tissues suggested that the major sites of retention (and therefore possibly of metabolism) of the material were in the liver and in muscle (8 per cent each), as has also been found for ^{14}C-dextran[11]. High retention in the liver has previously been found for other labelled polysaccharide sulphates (namely, 7·2 per cent for cellulose ^{35}S-sulphate[12] and 9·0 per cent for one preparation of low molecular weight xylan ^{35}S-sulphate[13]). The significance of the relatively high radioactivity found in the kidneys in the present experiment (3·55 per cent) is less clear since this might be accounted for partly by this organ being the one chiefly concerned in the excretion of dextran sulphate[2] and therefore probably containing ^{14}C-dextran sulphate in process of excretion in the urine.

The sample of dextran sulphate used for the experiments described underwent decomposition before further biological experiments could be carried out. It seems likely that decomposition was initiated by self-irradiation and continued autocatalytically under acidic conditions. Details of this work will be published elsewhere.

We thank Profs. M. Stacey and J. R. Squire for their interest and for providing facilities. We are indebted to Prof. E. J. Bourne and Dr. C. R. Ricketts for helpful discussions throughout the work, and to Dr. W. F. R. Pover for advice and the loan of the closed-circuit apparatus used. We also acknowledge gratefully generous financial assistance from Messrs. Glaxo Laboratories, Ltd., for this work.

Passive Antibody Decay in Thyroidectomized Rabbits

In the course of an investigation of the immune response of rabbits exposed to a low environmental temperature (– 15° C.) it was noted that the decay-rate of passively administered homologous antibody was increased[1]. Reference has been made to the fact that thyroxin-treated rabbits also exhibit an increase in passive antibody decay[2]. The fact that an animal metabolizes protein more rapidly under conditions of cold stress or when treated with thyroxine leads one, *a priori*, to consider more closely the influence of the thyroid on the immune response under cold stress. The following preliminary investigation was therefore undertaken to determine the effect of surgical thyroidectomy on the rate of decay of passively administered homologous antibody.

Adult male rabbits weighing 2·5–3·0 kgm. were used in this study. Five were surgically thyroidectomized and allowed to recuperate for 2–3 weeks before being injected with antibody, at which time their metabolic rate was approximately 75 per cent of normal. Ten untreated rabbits were used as controls.

The antibody used in this study was homologous γ-globulin prepared from high-titre anti-bovine serum albumin rabbit serum by one-third saturation with ammonium sulphate at *p*H 7·8. The γ-globulin so obtained was reprecipitated twice, dissolved in 1 per cent pyrogen-free sodium chloride, and the residual ammonium sulphate removed by dialysis against 1 per cent sodium chloride. Each animal was injected intravenously with 15 ml. of the γ-globulin solution, which contained approximately 170 mgm. of precipitable antibody protein. The animals were bled at intervals and the circulating antibody concentration estimated by the quantitative micro-precipitin analyses by a modification of the method of Lanni *et al.*[3]. The results were plotted semi-logarithmically as the percentage of the injected dose remaining in the circulation versus time (Fig. 1). The slope of the linear portion of the curve (assumed to represent steady-state loss of antibody) was calculated by the method of least squares, extrapolated back to zero time, and half-life values calculated from that point.

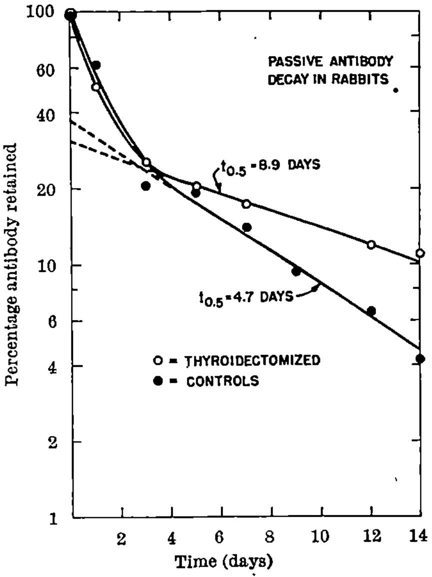

Fig. 1. Semi-logarithmic plot of percentage of injected antibody remaining in circulation versus time in days

The half-life of passively administered homologous antibody in the thyroidectomized rabbits was 8·9 ± 0·4 days compared to 4·7 ± 0·2 days for the untreated controls.

Previous work by others has indicated that thyroxin decreases and propylthiouracil increases antitoxin production in rabbits, but has the opposite effect in guinea pigs[4]. This species difference is attributed in part to a thyroxine-induced adrenocortical hyperactivity, which may have a greater effect in depressing antibody production in the 'cortisone-sensitive' rabbit than in the 'cortisone-resistant' guinea pig. The significance of these results and our own in relation to the immune response under stress conditions raises the question as to whether a change in circulating antibody-level would be due primarily to an alteration in the antibody-forming mechanisms, or would be due to the effect of these conditions on the mechanisms responsible for antibody decay. If the changes in antibody decay are considered as being superimposed on an essentially normal rate of antibody production, the net result would be an apparent decrease in the immune response of thyroxin-treated rabbits and an apparent increase in the immune response of hypothyroid rabbits. If, on the other hand, there is also an alteration in the rate of antibody production, then the net result would be either an accentuation of the immune response, if antibody production was affected in the opposite direction, or perhaps no observable difference, if a change in antibody decay was offset by a change in antibody production in the same direction, that is, an increase in antibody decay compensated by an increase in antibody production. Further study on the influence of the thyroid on the immune response is indicated, and experiments on active antibody production are now in progress.

This investigation was supported in part by the Office of Naval Research, *NR*102–392, and in part by the National Institutes of Health, U.S. Public Health Service.

Balance Trials with Magnesium-28 in Sheep

Fæcal magnesium comprises two fractions, an endogenous fraction originating from the body and excreted into the gut and an exogenous fraction representing unabsorbed dietary magnesium. Once the relative proportions of these two fractions are known, it is possible to calculate both the endogenous fæcal magnesium and the true availability of dietary magnesium. A method for determining these proportions would seem to be the comparative balance technique[1], since this could be adapted for magnesium-28 provided the quantity of this isotope in a single dose was sufficient for accurate determination of the total eliminated in the fæces after either oral or intravenous administration. As the cost of magnesium-28 is very high the size of dose for economic reasons must be small, but this communication describes experiments which would appear to be satisfactory from both points of view.

Cyclotron-produced 'carrier-free' magnesium-28 was used, and initially the doses contained 80 μc., but after chemical separation and transit, only about 30–40 μc. remained for administration into the sheep. The cost of each dose was £30.

Trials were carried out with one sheep, an adult North Country Cheviot wether, which received a constant diet of hay supplying 0·77 gm. of magnesium a day throughout the experiment. Single doses of magnesium-28 were given at 8.40 a.m., either into the rumen through a fistula, or into the jugular vein by means of a nylon catheter. The fæces and urine were collected twice daily at 8.40 a.m. and 4.40 p.m. and their radioactivity determined in a modified ring counter[2].

After ruminal administration it was found that magnesium-28 could be followed in the fæces for 5 days only. Nevertheless, it was possible to calculate the magnesium-28 still to be eliminated in the fæces since the ratio of magnesium-28 to dry matter in the fæces declined exponentially after reaching a peak on the second day after administration. This can be expressed by the following equation:

$$R = 0{\cdot}304 \exp(-0{\cdot}0306t)$$

where R is magnesium-28 recovered in fæces/magnesium-28 administered × 100/fæcal dry matter and t is time after administration (hr.).

Of the original dose, 62·6 per cent was recovered from the fæces within the period 2–5 days after administration, and it was calculated by integration of the above formula that a further 3·4 per cent would be eliminated by the same route after 5 days. These, together with the 13·2 per cent passed out on the first day, make a total of 79·2 per cent of the ruminal dose eliminated in the fæces. In the first 5 days, 0·07 per cent was excreted in the urine. Over the same period the fæcal non-radioactive magnesium represented 100·8 per cent of the dietary intake.

Following intravenous injection, urinary magnesium-28 could be followed for 5 days and fæcal magnesium-28 for 4 days 8 hr., and over this period 11·9 and 19·4 per cent of the given dose were excreted by the separate routes. The value for urinary magnesium-28 is much greater than those reported for calcium-45 in cattle[3], suggesting that the urinary route of excretion is more important for magnesium than it is for calcium.

The calculated values for the endogenous fæcal magnesium and the availability to the sheep of the magnesium present in hay were 205 mgm./day and 25·8 per cent respectively. These values are in good agreement with those determined for similar sheep by Field *et al.*[4] using indirect methods.

The evidence presented here shows that the true availability of dietary magnesium can be determined with magnesium-28, but its use will be limited by its high cost and its short half-life, which results in a severe reduction of its radioactivity in transit.

My thanks are due to Dr. J. R. Greening and Mr. P. Tothill, Department of Medical Physics, University of Edinburgh, for their valuable help.

Metabolism of Benzene Hexachloride by Resistant Houseflies *Musca domestica*

Our previous work on the metabolism of isomers of benzene hexachloride by a resistant strain of houseflies showed that the α- and γ-isomers are rapidly converted to water-soluble metabolites[1–3], and in the course of the reaction chloride ions are formed in the proportion of four or more per molecule of benzene hexachloride metabolized[4]. We have now found that alkaline hydrolysis of the metabolic products produces dichlorothiophenols.

The method of isotopic dilution was used for identifying the thiophenols, which have not yet been isolated. The Jealotts Hill strain of flies resistant to benzene hexachloride[5] was exposed to α- or γ-benzene hexachloride labelled with carbon-14 in a closed flask for 24 hr. and then extracted with 80 per cent ethanol. To this extract was added 200 mgm. of pure unlabelled dichlorothiophenol and the mixture subjected to alkaline hydrolysis with sodium hydroxide at 100° C. for 30 min. The dichlorothiophenol was then converted to a derivative, either by oxidation with iodine to the disulphide $(Cl_2C_6H_3S)_2$ or by reaction with chloroacetic acid to the dichlorophenyl thioglycollic acid $(Cl_2C_6H_3.S.CH_2.CO_2H)$. The derivative was isolated and repeatedly crystallized until the radioactivity measured in a flow-type proportional counter could no longer be reduced, even with change of crystallizing solvent.

Each of the six dichlorothiophenols was tested in this way with the results shown in Table 1.

Table 1. DICHLOROTHIOPHENOLS PRODUCED BY ALKALINE HYDROLYSIS OF METABOLITES OF BENZENE HEXACHLORIDE FROM HOUSEFLIES RESISTANT TO γ-BENZENE HEXACHLORIDE

Position of chlorine atoms	Percentage of total water-soluble benzene hexachloride metabolites	
	α-Benzene hexachloride	γ-Benzene hexachloride
2 : 3-	2*	< 1*
2 : 4-	20* 21†	32*
2 : 5-	21* 19†	16* 14†
2 : 6-	5*	9*
3 : 4-	19* 22*	5* 4†
3 : 5-	< 2*	< 2*

* Using thioglycollic acid derivative.
† Using disulphide derivative.

The figures show that alkaline hydrolysis of metabolites of benzene hexachloride produce dichlorothiophenol amounting to approximately 68 per cent of the water-soluble products from the α-isomer and 61 per cent from the γ-isomer. It is inferred that the metabolism of benzene hexachloride by the flies to produce water-soluble compounds involves the formation of a C—S bond. The nature of the initial metabolic product is not known; but it is suggestive that aryl mercapturic acids produced from halogen compounds in mammalian detoxication processes[6] are converted to thiophenols by alkaline hydrolysis[7].

A scheme which would satisfactorily account for the production of dichlorothiophenols from benzene hexachloride is set out below, but it is emphasized that we have at present no evidence in support of this other than that offered above.

$$C_6H_6Cl_6 + HS\mathit{R} \rightarrow C_6H_6Cl_5.S.\mathit{R} \rightarrow C_6H_3Cl_2SH + \mathit{R}OH + 3HCl$$

In this reaction the nature of *R*SH is unknown, but it is possible that the compound may be reduced glutathione. This compound, which has been shown by Kearns and his colleagues[8] to be essential for the *in vitro* enzymatic conversion of DDT to its monodehydrohalogenation product DDE, we now know to be essential also for the benzene hexachloride process *in vitro*.

Following in detail the methods employed by Kearns we have been able to convert α- and γ-benzene hexachloride to water-soluble compounds *in vitro* using fly macerates, acetone powders prepared from macerated flies, and impure enzyme preparations made from fly extracts by cold fractional precipitation with ammonium sulphate. The products of the *in vitro* enzyme reactions have been shown to yield thiophenols by alkaline hydrolysis. The *in vitro* reaction did not proceed in the absence of added glutathione.

Effect of Chloral Hydrate on Growth of Hair

STUDIES on the percutaneous toxicity of liquids applied as small (100μ) droplets to the guinea pig have shown that the presence of hair prevents some of the droplets from reaching the skin. Consequently, when the test liquid is applied in this droplet size, it shows less toxicity than an equivalent weight of large (400μ) droplets[1].

In percutaneous toxicity studies in the guinea pig, it is usual in this laboratory to apply the test liquid to animals 24 hr. after they have been clipped or chemically depilated. This 24-hr. period is allowed to minimize the effects on the skin of the hair-removal procedures. Although some species, such as the rabbit, show no appreciable hair growth 24 hr. after depilation, a very considerable growth occurs in the guinea pig.

The present experiment was conducted to determine whether or not this rapid regeneration of hair could be prevented. The inhibiting drug chosen for the investigation was chloral hydrate. Butcher[2], in studies on the hair cycle of the rat, reported that the hair follicles were inactivated by the subcutaneous injection of this drug. He did not mention the dosage used, or the duration of the treatment. The dosages chosen for the present experiment were 50 mgm./kgm. and 100 mgm./kgm., which are well below the hypnotic dose[3] of 250 mgm./kgm.

As test animals, 12 male and 12 female guinea pigs weighing 700–800 gm. were chosen. They were divided into three groups each with 4 males and 4 females. The animals in one group received 100 mgm./kgm. of chloral hydrate, those in another group 50 mgm./kgm. of the drug and the third was the control group. The chloral hydrate was dissolved in saline (160 mgm./c.c.) and daily injections were made subcutaneously for 14 consecutive days. On the fifteenth day, all animals were depilated with a barium sulphide paste. 24 hr. later, it was noted that the control animals all showed the usual rapid hair growth, whereas in all the animals treated with the drug the growth was inhibited to a considerable extent. No differences in effect could be noticed between the two dosage-levels, nor between male and female animals.

Several depilated animals were observed over a period of 6 days in order to study the effect of the drug on subsequent regrowth of hair. It is quite evident that the inhibiting action of the drug persists for at least 7 days after its administration has been discontinued.

The results of the present experiment indicate that, by using guinea pigs treated with chloral hydrate, the comparative percutaneous toxicity of large and small droplets of liquid chemical substances may be investigated without the interfering effect of hair.

This work was carried out in the Physiology Section, Defence Research Board of Canada, Suffield Experimental Station, Ralston, Alberta, under project No. *D*-52-89-50-15.

Crystals of Riboflavin making up the Tapetum Lucidum in the Eye of a Lemur

The tapetum lucidum of the eye is a specialized layer lying behind, but adjacent to, the light-sensitive cells of the retina. It is specialized to form a reflecting surface so that any light not absorbed during its first passage through the light-sensitive cells is reflected back again and has a second opportunity to be absorbed. The tapetum is the basis of eye-shine in animals ; it may be made up of crystals or of regularly arranged fibres[1,2]. Many fish, for example, have tapeta made of crystals of guanine, carnivores one of crystals of a complex of zinc-cysteine[3], while herbivores such as the sheep and cow have fibrous tapeta. Man and the higher apes have no tapetum ; but some lemurs have a well-developed one ; the brilliant yellow tapetum of *Galago monteiri* is described by Johnson[4], who says " . . . the background resembles burnished gold". Rochon-Duvigneaud[5] has found that both diurnal and nocturnal lemurs may have a tapetum. Kolmer[6] agrees with this and notes that the tapetum of *Lemur rufifrons*, a diurnal lemur, is both crystalline and yellow. Luck[7] has found that the eyes of *Galago crassicaudatus agisymbanus*, a nocturnal lemur, have a fluid vitreous body and a highly developed cellular tapetum which is brilliant gold in colour.

Through the kindness of Prof. C. P. Luck, I have examined the eyes of this lemur *Galago crassicaudatus agisymbanus*, and the evidence suggests that the tapetum is made of crystalline riboflavin.

Examination in vivo. The fundus of the eye viewed ophthalmoscopically shows a brilliant yellow-green central area with a peripheral pigmented part. With pupils dilated and in sunlight a green-yellow reflexion can be seen ; this is also observable, though less marked, if ultra-violet light from a mercury arc lamp is shone into the eye, which makes it probable that the light reflected through the pupil is due at least in part to fluorescence.

Examination in vitro. The central area of the fundus in the opened eye is brilliant yellow. When the retina is removed the brilliance is more marked and is, as Johnson says, like burnished gold. Much of the yellow material can be brushed or scraped off the underlying choroid and when examined microscopically with polarized light shows flat crystalline plates of irregular size (Fig. 1). Where the plates overlap they are yellow. Using acetone as fixative, sections can be made showing crystals lying immediately behind the retinal pigment epithelium, which is devoid of pigment in the central tapetal area. The crystals were, however, irregularly arranged, totally lacking in some parts and appearing more like needles or rods than flat plates (Fig. 2) ; probably even acetone fixation allows some solution and rearrangement of the crystals. When examined under ultraviolet light the crystals in the section of the eye fluoresced bright yellow.

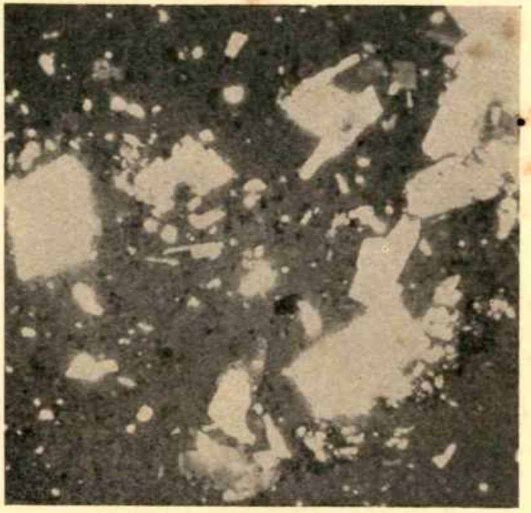

Fig. 1. Crystalline material brushed off the tapetum of *Galago crassicaudatus* and examined with polarized light

Identification of crystals as riboflavin. The yellow material either from tapetal material dried in acetone or from the tapetal scrapings was dissolved in water or 1 per cent formic acid. Such solutions are yellow and show yellow-green fluorescence. The absorption curve in 0·1 per cent formic acid showed peaks at 266 mμ, 370 mμ and 445 mμ, the peak at 266 mμ being the greatest. Light of 285 mμ, 395 mμ and 470 mμ was used to elicit fluorescence at 530–550 mμ. Both the absorption curve and the fluorescence corresponded with those of riboflavin determined at the same time. Duggan *et al.*[8] give 520 mμ as the fluorescence maximum of riboflavin ; it is probable that the

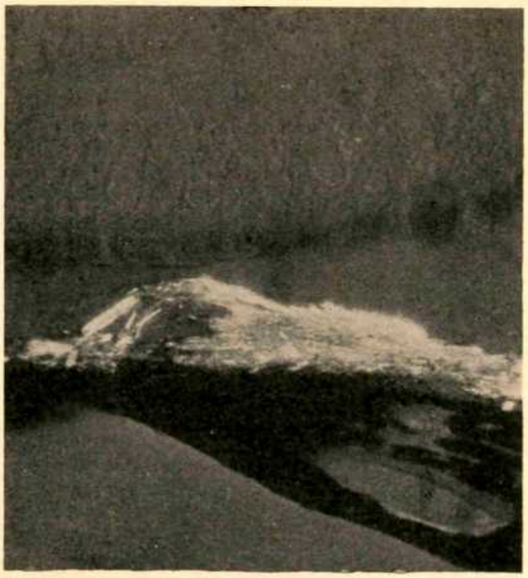

Fig. 2. Section of eye of *Galago crassicaudatus* showing crystalline tapetum lying between the retina and the choroid (polarized light)

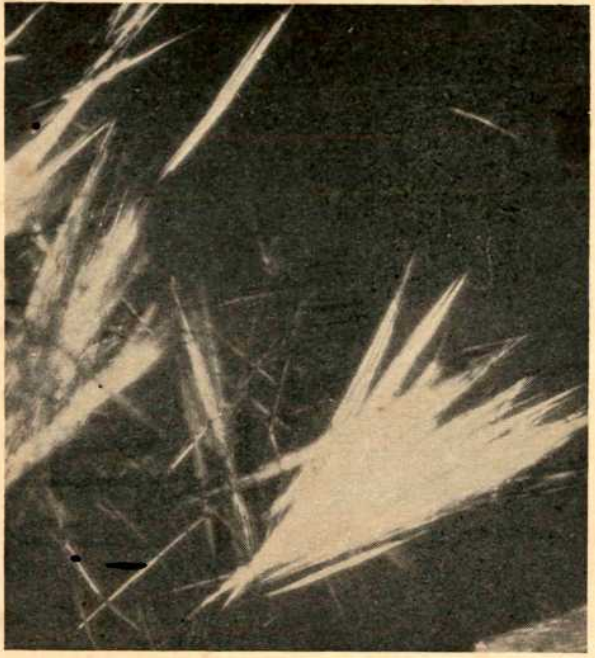

Fig. 3. Crystals deposited from solution of tapetal material in 1 per cent formic acid

maximum at 530–550 mμ found in experiments is due to slight instrumental error. The tapetal material corresponded exactly with free riboflavin in solubility, chromatographic behaviour, formation of a chloroform-soluble substance on irradiation with ultra-violet light in alkali and of a blue fluorescent substance on irradiation in acid, and in being reversibly reduced to a colourless, non-fluorescent substance by sodium hydrosulphite.

It seemed, therefore, probable that the crystalline tapetum lucidum of this lemur is made of riboflavin. The only divergence is of crystal form. Typical riboflavin crystals are needles and such needles were deposited from a 1 per cent formic acid solution of the tapetal material (Fig. 3); but the fresh tapetum itself, scraped off and examined at once, contained only plates. As the tapetum of carnivores and the choroids of some fish[9] contain very large amounts of zinc, the formic acid extract of the tapetum was examined spectrographically to see if any metal was present in abnormally large amount, but none was found. However, it seemed possible that the plate crystals of the tapetum contained riboflavin in association with some other substance. Mrs. D. M. Hodgkin very kindly took X-ray powder photographs of the tapetal material, fresh from the eye, and finds it to be identical with one of the plate forms of riboflavin obtained by recrystallizing a commercial preparation. Sakate[10] has noted plate forms of riboflavin.

Crystals of riboflavin have been described in cells of the fungus of *Erymothecium ashbyii*[11], and Euler and Adler[12] noted that the eyes of many fish contain a high concentration of riboflavin but did not report crystals. Apart from the fungus, the tapetum of this lemur seems to be the only biological material where crystalline riboflavin has been found. Riboflavin is soluble in water to 19 mgm./100 ml. at 40° C. and the biochemical reactions which deposit and maintain it as crystals in the tapetum are unknown.

It is impossible not to consider that the tapetum will influence light reception and vision. First, light passing through the retina will be reflected by the tapetum so that the reflected light will be yellow. Second, the fluorescence maximum of riboflavin is 520 mμ at neutrality[8], and this fluorescence is maximally activated by light of 445, 370 and 266 mμ. Light of 445 and 370 mμ will penetrate the eye, be absorbed by the tapetum and re-emitted as light of 520 mμ, owing to the fluorescence of riboflavin. Dodt and Walther[13] find that the sensitivity of the light-adapted retina of the cat is much greater in the tapetal than in the non-tapetal area though there is no difference in the dark-adapted eye. Dodt[14] has also found that injection of fluorescein in the albino rabbit increases the sensitivity of the retina. If lemur eyes contain visual purple with an absorption maximum of 500 mμ and hence a visual sensitivity which is greatest to light of this wave-length, it should benefit an animal to have shorter wave light transformed into light of 520 mμ. The absorption by visual purple is 50 per cent maximal at 445 mμ and 90 per cent maximal at 520 mμ[15]. In both these ways —as a reflector, and as a fluorescing substance—riboflavin may therefore increase the stimulus received by the light-sensitive cells.

I wish to thank Dr. H. Davson for the gift of two lemurs (*Galago crassicaudatus*), Prof. R. T. Williams and Mr. Rosen for determining the fluorescence spectrum of the tapetal extract, Dr. H. H. le Riche for examining the tapetum spectrographically and Mr. Reading for help with ultra-violet microphotography.

Gas Secretion in Coregonids

IT is known that the coregonids do not possess a counter-current system in the vascularization of the swim-bladder. In his classical work Hüfner[1] showed that *C. acronius* has a gas content in the swim-bladder consisting mainly of nitrogen—some 99 per cent. This was later verified by others[2–4] on *C. acronius* and related species.

Then the question arose whether this gas mixture is primarily secreted. All attempts by artificial stress to make coregonids secrete have hitherto been unsuccessful.

As reported previously[4] the Norwegian *C. lavaretus* was found to secrete oxygen. A single specimen of *C. acronius* caught by me in the Bodensee in May 1957 had an oxygen content of 30·8 per cent. Assuming that periods of secretion and non-secretion occur, the question is whether the former investigations had been performed in the period of non-secretion. A further investigation on *C. acronius*, the classical material of Hüfner, was therefore initiated in October. The fishes were caught at a possible secreting period. Ten specimens were caught near Unteruhldingen by gill nets at depths of 80–100 m. Flotation measurements of the fishes gave buoyancy depths of 81–120 m. All the specimens had an oxygen content ranging from 15·2 to 18·3 per cent. By mass-spectrometry the argon/nitrogen ratio was measured, giving values of 90·1–97·0 per cent of the air.

The relatively low oxygen content may indicate that the secreting period is terminated and the oxygen is being absorbed. The low argon content is in favour of this theory[4].

The same process has been shown by experiments by me to occur in a physoclist fish (*Gadus callarias*). The fish was over-inflated with a mixture of 23·4 per cent nitrogen and 73·7 per cent oxygen. After 4 days the fish showed normal buoyancy with a gas content in the swim-bladder consisting of 95·5 per cent nitrogen and 3·7 per cent oxygen.

The results obtained indicate that the problem of secretion is common for the physostome and physoclist fishes, and the lack of a counter-current system does not exclude oxygen secretion.

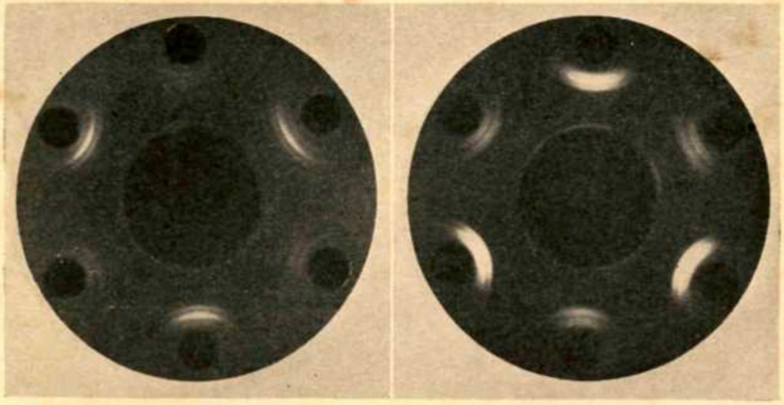
A Critical Test of Antigenic Relationships

A NEED has long existed for a simple, direct method for determining whether cross-reacting antigens are identical, or merely similar. Isolation and immunochemical characterization of individual antigens are often impossible. Measurement of precipitation or agglutinin titres, or of optimum proportions, are generally too crude to make distinction between identity and similarity possible, and may lead to confusing results[1]. Wodehouse[2] has reported the method of cross-neutralization to be unsuited for antigenic analysis of allergens.

Introduction of the immuno double-diffusion gel plate technique by Ouchterlony[3] apparently provided the required means for studying antigenic relationships. Complete fusing of precipitation bands of two antigens was taken to indicate antigen identity. Spur information was postulated, required and, in many cases, observed in antigen similarity without identity. Unfortunately, the conventional Ouchterlony technique can be deceptive. Its application has misled several investigators to postulate an identity of the major antigen(s) of the pollens of different species of grasses[4–6].

Re-investigation of grass pollen antigen relationships by a new agar gel technique has produced conclusive evidence of antigenic similarity rather than identity. The method is based on a modification of a pattern and technique published previously[7,8]. It is simple and permits analysis of complex antigen mixtures as well as isolated antigens.



(*a*) (*b*)

Fig. 1. Difference between precipitation band intensities of homospecific and cross-reacting heterospecific antigen/antibody systems. Outer wells contain, alternately, extracts of brome (*Bromus mollis*) and cocksfoot (*Dactylis glomerata*) pollens, starting with brome in top well. *a*, Antiserum to cocksfoot pollen in central well; *b*, antiserum to brome pollen in central well

Patterns are cut in the agar with an accurately tooled cutting instrument (obtainable from the Shandon Scientific Co., London, S.W.7). Two plates are used for the comparison of two antigen solutions. In the central well of one plate is placed 0·2 ml. antiserum to one of the antigen solutions. The other plate similarly receives the antiserum to the other solution. Antibody gradient is established in the agar by incubating the plates with the sera at 37° C. for 24–72 hr. Suitable concentrations of the two antigens are then placed in alternate circumferential wells in both plates and the plates incubated for a further 24 hr.

If the antigens are identical, the precipitation patterns at all wells are of equal intensity. Where a similarity without identity exists, alternate wells will show strong and weak precipitation band patterns, the positions being reversed in the two plates. In each plate the homospecific antigen gives strong bands, the related heterospecific antigen weak bands (Fig. 1).

The technique has been thoroughly tested on both complex and simple antigen systems. It has been found to be a critical and discriminating test of antigenic relationships. Extension of observations and theoretical considerations will be made the subject of a subsequent paper.

Photographs of the gel plates were made on the Lawson apparatus[9].

PLANT PHYSIOLOGY

Copper–Cellulose Complexes

OUR attention has been directed to the fact that our recent paper[1] on the subject of timber preservation by copper compounds is being quoted in the literature[2] in support of the copper–cellulose hypothesis of Abrams and Bottoms[3].

These workers and their associates have concluded, largely from indirect evidence, that after treating wood or cellulose with a copper formate solution followed by autoclaving or heating, the copper is converted into a copper–cellulose complex and that this complex confers durability. This is known as the N.C.G. process, and its use has been advocated for wood, cotton and other cellulosic materials as a preservative measure.

During our examinations in the electron microscope[1,4] of wood treated with water-soluble preservatives or aqueous solutions of metal salts, characteristic electron diffraction patterns were noted which were interpreted as referring to metal–cellulose complexes in the wood. This interpretation was later confirmed[5,6], and the electron-diffraction diagrams were shown to arise from a two-dimensional array of metal atoms adsorbed on to the surface of cellulose microfibrils.

The properties of this metal–cellulose complex, however, do not appear to be consistent with the claims of Abrams and Bottoms. We have found that complexing takes place in the cold from aqueous solutions of copper salts so that no heat is necessary for the adsorption and, in addition, the electron diffraction pattern given by the complex remains unchanged after heat treatment. Cations from solutions of metal salts, other than those of copper, form a metal–cellulose complex so that the reaction is not restricted to copper formate solutions.

Abrams and Bottoms have claimed that N.C.G.-treated cellulose is resistant to hydrolysis and will not dissolve in concentrated hydrochloric acid, whereas we have found that, in the case of the complex detected by means of electron diffraction analysis, the 'bound' copper is instantly removed by dilute acids.

Thus, while our investigations have confirmed the existence of a metal–cellulose complex, the configuration of which has been elucidated by means of electron diffraction analysis, the general behaviour of this complex does not resemble that of the copper–cellulose complex postulated by Abrams and Bottoms, and our findings can in no way be taken to support their copper–cellulose hypothesis.

Tetragonin : a Yeast Growth-regulating Substance from *Tetragonia expansa*

THE number of antimicrobial substances isolated from higher plants is small. Recently, studies with *Tetragonia expansa* or New Zealand spinach have shown it to contain a water-soluble component which we have tentatively named 'tetragonin'. Tetragonin is characterized by a narrow spectrum, being active apparently specifically upon *Saccharomyces* spp.

Activity tests were conducted with the agar diffusion paper disk method[1] using 1-day-old cultures of *Saccharomyces carlsbergensis* ATEE 9080 as test organism. The medium containing 2 per cent malt extract and 1 per cent agar, inoculated with approximately 5×10^7 cells/ml., was spread on glass plates in layers 1 mm. thick.

A preparation was purified by addition of chloroform to the centrifuged juice obtained from the stems of well-developed plants. The supernate was kept on a steam-bath for 10 min. and then centrifuged. The addition of one part ethanol to two parts of the supernate resulted again in precipitation. This supernate was dried at 50° C. and dissolved in methanol. After drying, a hygroscopic, yellow, sweet-smelling substance was obtained.

A methanolic solution of this partially purified substance was chromatographed on Whatman No. 1 filter paper. The dried chromatograms were placed on top of agar plates inoculated with *Saccharomyces carlsbergensis*. The R_F values thus obtained with 3 : 2 mixtures of methanol–water were 0·44–0·46, with 3 : 2 mixtures of ethanol–water 0·39–0·40 and of 3 : 2 mixtures of acetone–water 0·38–0·39. The same R_F values were obtained using the eluate of the chromatogram and also with the crude leaf juice. Tetragonin is very soluble in water, soluble in methanol, scarcely soluble in absolute ethanol and *iso*propanol, and insoluble in benzene, carbon tetrachloride, toluol and chloroform. The compound is stable at 100° C. for about 20 min., then undergoing decomposition. This decomposition with respect to time is logarithmic. The relationship between zone diameter and the logarithm of concentration is a straight line. Tetragonin dried on filter paper retains its activity for at least one year.

Tetragonin in high concentration inhibited, but in lower concentration stimulated, the multiplication also of several types of *Saccharomyces cerevisiae* and of *S. cerevisiae* var. *ellipsoideus*, in addition to *S. carlsbergensis*. No activity was observed with the following micro-organisms :

Yeasts : *Schizosaccharomyces octosporus*, *Endomyces magnusii*, *Sporobolomyces* sp., *Endomycopsis fibuliger*, *Rhodotorula gracilis*, *Torulopsis utilis*.
Bacteria : *Escherichia coli*, *Serratia marcescens*, *Bacillus subtilis*, *B. cereus*.
Actinomycetes : *Actinomyces roseus*, *Streptomyces floridae*, *Proactinomyces roseus*, *Nocardia grisea globispora*.
Phycomycetes : *Rhizopus nigricans*, *Mucor* sp.
Ascomycetes : *Aspergillus ruber*, *Penicillium striatum*.
Basidiomycetes : *Puccinia graminis*
Fungi Imperfecti : *Aspergillus niger*, *A. flavipes*, *Penicillium chrysogenum*, *P. notatum*, *Trichothecium roseum*, *Colletotrichum lini*, *Botrytis cinerea*, *Cercospora beticola*, *Pullularia pullulans*.

Tetragonin is present throughout the plants, and though its concentration varies considerably during the period of cultivation, it is always the highest in the roots. In the young plants the leaf juice shows higher activity than that of the stem, but as the plant ages, the activity of the stem becomes higher than the activity of the leaves, while the activity of the lower stem parts approaches that of the roots. Green unripe fruit show an activity between that of the leaves and stems. The aqueous extract of the dry ripe fruit showed no signs of activity.

These observations indicate a new antibiotic substance from a higher plant. That the antibiotic is very specific for *Saccharomyces* spp. may lead to industrial application. That the concentration in the plant roots is the highest may indicate an ecological role, a feature also indicated by the macrocounteractions observed in Nature.

These experiments were begun in the Plant Breeding Research Institute, Sopronhorpacs, Hungary, and were finished at the Universities of Wisconsin and Bologna.

Separation of Anthocyanins from Plant Extracts

ALTHOUGH cellulose column chromatography[1] is generally useful for the separation of anthocyanin mixtures, difficulties may be encountered in applying this technique in the presence of large amounts of other flavonoid materials. Thus, in the case of complex petal extracts, overlapping of bands can occur so that the anthocyanins are contaminated with other pigments; and in the case of extracts containing mobile leuco-anthocyanins, the anthocyanin bands are located within a broad diffuse zone containing the former compounds. While these difficulties can be overcome by further purification involving partition between solvent systems, or repeated cellulose column chromatography, a very convenient and effective method is provided by preliminary treatment on a column of polyamide[2-4].

The general application of polyamide (powdered nylon) columns in the purification of flavonoids has already been reported[3,4], the separations achieved depending on two factors: the greater solubility of glycosides in water as compared with aglycones, and the strong absorptive capacity of the powdered nylon for hydrogen-bonding phenolic groups. Thus flavonoid glycosides can be separated from their aglycones by using aqueous methanol followed by anhydrous methanol for elution; but compounds of the same class cannot be separated from one another by this method. It seemed likely that using a combination of the two absorbents (cellulose favouring the retention of water-soluble compounds, polyamide the reverse) it would be possible to separate most mixtures of flavonoid compounds.

Preliminary investigations showed that anthocyanins and anthocyanidins are only slightly retained by polyamide columns, being readily eluted by the usual anthocyanin solvents providing they are sufficiently acid to prevent fading of the pigment. The upper layer of butanol – 2 N hydrochloric acid was found to be most suitable, and had the added advantage that the eluates could be applied directly to the cellulose column[1]. Addition of two parts by weight of 'Celite' to the polyamide hastened the movement of the solvent through the column and did not greatly diminish the absorptive properties of the polyamide.

The polyamide–'Celite' mixture was packed as a slurry in the solvent system and pressed firmly into the column to a uniform compactness using a closely fitting tamper. The pigment extracts were added as a strong solution in the solvent system, to which a little methanol was added if necessary to assist the solution of the difficultly soluble components. On development with aqueous acidic butanol both anthocyanidins and anthocyanins moved rapidly down the column as one band; most of the other flavonoids were more firmly held in this solvent system but could be separated if required by further elution with aqueous or absolute methanol[3,4]. Monomeric leuco-anthocyanins, however, were found to move off the column on continued elution with aqueous butanol, and this technique offers a method for the separation of anthocyanins from leuco-anthocyanins, superior to that previously published[5], in that both fractions are recoverable.

This technique has been applied successfully to extracts of *Dahlia* petals, *Streptocarpus* petals and cacao beans, anthocyanins being obtained free from other flavonoid compounds. Anthocyanidins from acid-treated leuco-anthocyanin solutions could also be obtained in a pure state using this method, accompanying polymeric material being absorbed firmly on the column[2].

Such polymeric material could not be completely removed from the column even by alkali washing, but in all other cases the polyamide, which is apparently not affected by the recommended solvent system, can be freed from absorbed compounds by washing with suitable solvents, and used again. It is to be hoped, however, that this extremely useful and potentially cheap absorbent will become so readily available that this will not be necessary.

We wish to thank Dr. D. E. Hathway, British Leather Manufacturers' Research Association, for a liberal supply of polyamide, and Dr. J. Harborne, John Innes Horticultural Institution, for a gift of pure anthocyanins.

Effect of Coumarin on the Germination and Growth of Rice Seedlings

UNSATURATED lactones like coumarin, parasorbic acid, etc., came to prominence after the postulation of blastocholine, the group of unknown substances from the ripe fruits which were found to inhibit the germination of corn seeds. Work was further extended to study the physiological behaviour[1] as well as cytological effects[2] produced by these unsaturated lactones. Coumarin at high concentrations has been reported to have inhibitory effects in several plants[3-7]. The present investigation was designed to study the effect of coumarin (the lactone of *o*-hydroxy-*cis*-cinnamic acid) at various concentrations on the germination and growth of rice seedlings.

Graded seeds of the early variety of rice, *N.* 136, were soaked separately in the different concentrations, 0·5, 1, 5, 10, 100 and 1,000 parts per million of coumarin. Another set soaked in distilled water served as the controls. After 72 hr. soaking the seeds were thoroughly washed with distilled water and allowed to grow on moist filter paper in Petri dishes in the dark at room temperature. Three replications were maintained for each concentration. Six seedlings were taken at a time at random from each Petri dish, and readings were recorded at intervals on the length of the longest root, length of shoot, total fresh weight of all the roots and total fresh weight of the shoot.

The inhibitory effect of coumarin on the germination and growth of rice seedlings at high concentrations was very conspicuous. Seeds treated with 1,000 parts per million did not sprout at all, whereas the percentage of sprouting was almost the same as the controls in all other concentrations. Though the seeds treated with 100 parts per million sprouted as usual, their subsequent growth was very much adversely affected by this concentration. The radicle in this case emerged much later than the plumule and was marked with a conspicuous swelling of the hypocotyl. The initial inhibitory effect of this concentration, however, did not persist for long and rapidly diminished with the increase in the age of the seedlings. Lower concentrations behaved in a very different way. Much lower concentrations such as 0·5 and 1 parts per million produced significant accelerating effect on the growth of root as well as shoot. The maximum effect of 14·46 and 14·45 per cent increase in the length of the longest root and the shoot together with 63·27 and 29·12 per cent increase in fresh weights of all the roots and the shoot respectively over the controls was observed in the lowest concentration of 0·5 part per million.

With the increase in concentration to 5 parts per million a bifurcation in the effect of coumarin was observed in that the growth of the roots was inhibited while the growth of the shoot was still maintained on the accelerated side. With still further rise in concentration to 10 parts per million the inhibition of the growth of the roots was intensified and the direction of growth of shoot was reversed from that of promotion to inhibition. This onset of inhibitory effect simultaneously on both the roots and shoot which started at 10 parts per million persisted all through in the higher concentrations. The maximum effect of 56·56 and 36·31 per cent decrease in length of the longest root and the shoot together with 63·27 and 23·55 per cent decrease in fresh weights of all the roots and the shoot respectively in comparison with the controls was noted with 100 parts per million. Thus two things were marked from the behaviour of coumarin: (*a*) the ranges of concentration for acceleration of root and shoot growth are different, the optimum range of concentration for elongation of shoot being higher than that for root; (*b*) the accelerating effect was maximum at very low concentrations, with a gradual diminution of this effect with the rise in concentration and ultimately culminating in a reverse effect of inhibition beyond a certain stage at higher concentrations. Thus as has been observed for indoleacetic acid[8], roots and stems react in a comparable way to coumarin, their growth being inhibited by relatively high and promoted by relatively low concentrations.

BIOCHEMISTRY

Reduction of Menadione in Hexane by Chlorophyll a under Ultra-violet Irradiation

WE have found that chlorophyll can reduce vitamin K upon illumination. This reaction can be followed by the loss of fluorescence induced by exposure of chlorophyll to light in the presence of vitamin K. This loss of fluorescence occurs at concentrations and intensities of illumination at which the fluorescence of chlorophyll alone does not vanish. The reduction of vitamin K to the hydroquinone form can be shown by reduction of 2,6-dichlorophenol-indophenol.

The following experiments illustrate this finding. 1·85 mμmoles of chlorophyll *a* were mixed with 5 μmoles of menadione (2-methylnaphthoquinone, vitamin K_3) in 5 ml. hexane. The characteristic red fluorescence of chlorophyll *a* appeared whenever this solution was illuminated by light of wave-length 365 mμ from an ordinary black light source. Prolonged illumination by this source caused the fluorescence to fade. This was apparent within 15 sec. and extinction of the fluorescence was complete within 5 min. The fluorescence did not reappear within 48 hr. A solution of chlorophyll at the same concentration, without menadione, was not bleached under these conditions, nor did its fluorescence fade.

One method of analysis of vitamin K is to titrate its reduced (hydroquinone) form with 2,6-dichlorophenol-indophenol[1]. This reduction decolorizes the blue dye. 1 ml. of an aqueous solution of the sodium salt of 2,6-dichlorophenol-indophenol (1·33 μmoles) was decolorized to about half the original intensity of its blue colour when shaken vigorously with a chlorophyll–menadione solution which had been illuminated half an hour previously. Further shaking under 365-mμ illumination decolorized the dye completely in about 5 min. Neither chlorophyll nor menadione separately was able to reduce 2,6-dichlorophenol-indophenol under these conditions, nor was the dye itself decolorized when illuminated and shaken with hexane. Menadione itself reduced the dye when illuminated ten times as long as sufficed for decolorization of the dye in the presence of both chlorophyll and menadione. The same results were obtained with de-aerated solutions under nitrogen. The blue colour of the dye could be brought back after decolorization by oxidation with a very dilute aqueous solution of iodine and potassium iodide.

A number of reactions have been demonstrated by these experiments. Excitation of chlorophyll[2,3]:

$$\text{Chl} + 2\,h\nu \rightarrow \text{Chl}^* \qquad (1)$$

Transfer of electrons to menadione (K_3):

$$2\,\text{Chl}^* + K_3 + 2\,H^+ \rightarrow 2\,\text{Chl}^+ + H_2K_3 \qquad (2)$$

Transfer of electrons to 2,6-dichlorophenol-indophenol (DCIP):

$$H_2K_3 + \text{DCIP} \rightarrow H_2\text{DCIP} + K_3 \qquad (3)$$

The concentrations used in our experiment were such that the chlorophyll had to turn over at least a thousand times for complete reduction of the dye to occur. Therefore, a follow-up reaction to (2) must occur in order to return Chl+ to its original form. Since this reaction occurs when an aqueous phase is added to the system, we believe that the follow-up reaction consists of the oxidation of water:

$$H_2O + 2\,\text{Chl}^+ \rightarrow 2\,\text{Chl} + 2\,H^+ + \tfrac{1}{2}\,O_2 \qquad (4)$$

The occurrence of reaction (4) still has to be established, however.

The reduction potentials[4] involved in these reactions are:

$$2\,H^+(10^{-7}M) + K_3 + 2e \rightarrow H_2K_3 \qquad E^0 = 0{\cdot}009\ \text{V.} \quad (5)$$

$$2\,H^+(10^{-7}M) + \text{DCIP} + 2e \rightarrow H_2\text{DCIP} \qquad E^0 = 0{\cdot}217\ \text{V.} \quad (6)$$

$$2\,H^+(10^{-7}M) + \tfrac{1}{2}\,O_2 + 2e \rightarrow H_2O \qquad E^0 = 0{\cdot}815\ \text{V.} \quad (7)$$

The potential of half-reaction (5) shows that the reduction of menadione uses radiant energy absorbed in reaction (1) as activation energy, but that no energy storage in a thermodynamic sense has taken place. Other vitamin K components or analogues have more negative reduction potentials, so that energy storage would occur even in a thermodynamic sense upon the reduction of these compounds. The reversal of half-reaction (7), which is involved in reaction (4), would indicate a considerable storage of energy in the course of the latter reaction.

We hope that the reactions reported here will prove helpful in studying the mechanism of photosynthesis as well as in converting the energy absorbed by chlorophyll into useful products. Work leading to further elucidation of these reactions is being continued.

Determination of Molecular Weights of Polysaccharides by Over-oxidation with Periodate

IN addition to its capacity to oxidize α-glycol groups, periodate oxidizes C—H groups flanked by two α-carbonyl groups[1]. Such structures are exposed in the reducing-end units of 1 : 2-, 1 : 3- or 1 : 4-linked aldohexopyranose oligosaccharides when the α-glycol groups have been oxidized.

The requisite carbonyl groups for activation of the C—H bond are found as aldehyde groups. The oxidation of the C—H group creates new α-glycol centres and further oxidation (over-oxidation) ensues. The oligosaccharide is therefore slowly eroded from its reducing-end unit with the evolution of carbon dioxide from the carbon atom carrying the activated hydrogen. The reaction continues either until the molecule is completely converted into carbon dioxide, formic acid and formaldehyde, or until structures are encountered which are no longer over-oxidizable, for example 6-substituted monosaccharide units. This behaviour has previously been used for locating the position of 6-substitution in an oligosaccharide[2]. Another use of the over-oxidation reaction is in determination of degree of polymerization of an oligosaccharide, since the rate of over-oxidation is dependent on the content of reducing-end groups. When the laminaridextrins (1 : 3-linked β-glucose oligosaccharides)[3] were over-oxidized in unbuffered sodium metaperiodate at room temperature the rate of periodate uptake was found to be directly proportional to the reducing-end group content, and degree of polymerization of laminarin was determined by measuring its rate of over-oxidation in comparison with that of the laminaridextrins of known degrees of polymerization[4]. We have re-investigated this method in an attempt to reduce the period of measurement (> 100 hr.) and the amount of material required. The latter object was achieved by measuring the rate of liberation of formaldehyde with the sensitive chromotropic acid reagent[5]. The maltodextrins[6] (1 : 4-linked α-glucose oligosaccharides) were used as test substances.

In phosphate or bicarbonate buffer at neutral *p*H there was a marked increase in the rate of over-oxidation over that occurring in unbuffered periodate (*p*H 4); but the method was unsuitable because, in addition to the endwise erosion, a random breakdown of the polymers occurred. For example, Schardinger α-dextrin (*cyclo*hepta-amylose), which is non-reducing and should not yield any formaldehyde, produced 1·61 mol. prop. of aldehyde during 22½ hr. oxidation in phosphate buffer *p*H 7·0 at 23° C. Recourse was had to the use of acid media and in acetate-periodate *p*H 1·90 at 50° equimolar amounts of maltodextrins in the series maltose-maltopentaose were over-oxidized at exactly equal rates. The time of oxidation necessary for the accurate determination of the rate constant was only 2 hr. Synthetic amyloses of known average degree of polymerization[7] were then prepared and their rates of over-oxidation compared with those of the maltodextrins. The values of degree of polymerization of such amyloses determined by measurement of the rate of over-oxidation agree well with the known values of degree of polymerization of the amyloses (Table 1).

The amount of polysaccharide required for the estimation of degree of polymerization is about 1·5 mgm. and the period of measurement need not be more than 20 hr. With more material the period is

Table 1. DETERMINATION OF DEGREE OF POLYMERIZATION OF SYNTHETIC AMYLOSES

By synthesis*	By over-oxidation
20·1	21·5
36·4	36·6
43·7	42·3
53·7	52·4
68·7	70·1

* The amylose is synthesized by potato phosphorylase from glucose 1-phosphate and a known amount of pure maltodextrin primer. Measurement of inorganic phosphate liberated when the synthesis is terminated enables the increase in length of the primer to be calculated (ref. 7). In these experiments the primer was maltopentaose or maltopentaitol.

correspondingly less. The method probably cannot be applied to polysaccharides of degrees of polymerization of more than 100 since some depolymerization occurs in the acid medium used for the oxidation and the consequent error will increase as the degree of polymerization increases. At degrees of polymerization less than 100 the error proved to be negligible.

The method has been used in the determination of degrees of polymerization of other polysaccharides and oligosaccharides, and it is hoped to publish full details elsewhere.

Aerobic Fermentation of Whey by a Nitrogen-fixing Strain of *Aerobacter aerogenes*

DURING the course of investigations on the utilization of cheese whey by micro-organisms, a strain of *Aerobacter aerogenes* was found capable of growing in whey and increasing the total protein of the whey without requiring the addition of a fixed form of nitrogen. Various attempts to convert cheese whey into useful substances by microbiological means have been covered in the review by Wix and Woodbine[1]. Cheese whey is a waste product with a high potential energy source in the form of lactose which has been studied in this laboratory as a substrate for members of the genus *Azotobacter*[2]. This was concerned with increasing the protein content of whey by the production of bacterial cell material. *Azotobacter* will not use lactose. Since we found that hydrolysis of the lactose must be followed by the removal of salts and other toxic ingredients in order to support growth of *Azotobacter*, attention was directed to other micro-organisms. An economic advantage of the genus *Azotobacter* is its nitrogen-fixing ability. Hence, interest was turned to a nitrogen-fixing strain of *Aerobacter aerogenes* which was recently discovered in this laboratory[3]. Pirt[4] has shown that the efficiency of conversion of substrate carbon to cell carbon and carbon dioxide by *Aerobacter* is directly proportional to the degree of oxygenation of the culture. This indicated that fermentation of whey could be accomplished under aerobic conditions.

All fermentations reported here were carried out in New Brunswick Model *F*07 fermentors of 7·5-l. capacity. 5 l. of acid whey were neutralized with potassium hydroxide, added to a fermentor, and sterilized by autoclaving at 15 lb. pressure for 15 min. The fermentors were inoculated with young cultures of *Aerobacter aerogenes* 88, stirred at 320 r.p.m., and aerated at a rate of 10 l. of air per minute. The temperature of the fermentations averaged 30° C. Excessive foaming was controlled by the addition of 'Dowex *AF* Antifoam'. The fermentations were sampled periodically over their 6–12 day incubation periods. The suspended solids, including the cells, were removed by centrifugation, recovered by acetone trituration, and dried to constant weight. Microkjeldahl determinations were made for total nitrogen and were the basis of the protein values presented.

Analysis of a typical fermentation showed the protein of the liquid whey culture to be 10·9 gm./l. before fermentation and 15·7 gm./l. after 10 days, an increase of 4·8 gm./l., or 44 per cent. Interest was confined, however, to the centrifugable portions of the culture. The dry weight of this portion increased from 10 gm./l. at the outset to 13·7 gm./l. at the termination of 10 days incubation, an increase of 3·7 gm./l., or 37 per cent. The protein of the centrifugate was increased from 42·9 to 68·1 per cent during fermentation, an increase of 59 per cent. As indicated in Fig. 1, total nitrogen increased throughout the fermentation periods. These findings appear to indicate that some nitrogen fixation has occurred with aerobic cultural conditions. In this connexion, the report by Pengra and Wilson[5] shows a several-fold increase in cell nitrogen by growing *A. aerogenes* anaerobically, and adds that under their conditions

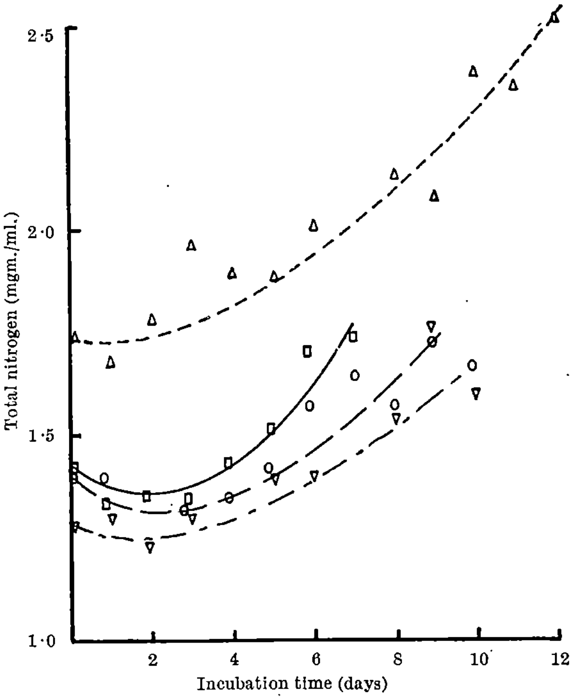

Fig. 1. Total nitrogen in four aerobic fermentations of whey by *A. aerogenes* 88 with incubation periods of 6–12 days. Each fermentation is with a different batch of cheese whey, which explains the difference in total nitrogen of the unfermented samples

their strains did not fix nitrogen aerobically. This is, of course, unlike the strain employed by Jensen[6], which fixed nitrogen equally well aerobically or anaerobically. One might also mention that Pirt[4] shows that in the presence of fixed nitrogen maximum conversion of carbohydrate to cell material occurs aerobically. Whereas Pengra and Wilson[5] employed a mineral salts and sucrose medium, Jensen[6] found a small amount of yeast extract or agar necessary. We were also unable to show nitrogen fixation unless whey or agar was present. This appears to suggest that a growth factor is required for aerobic nitrogen fixation by some strains of the genus *Aerobacter*.

This investigation was supported in part by a grant from the National Science Foundation.

Amino-Acid Metabolism in Wool Roots

FOLLICLE material referred to as wool roots can be prepared in quantity from fresh sheep-skin by Ellis's method[1]. Each wool root consists of a bulb region, a pre-keratinization region and some fully keratinized fibre. Frequently, the inner root sheath is found to be attached to the wool root. Previous studies of homogenates of wool roots revealed the presence of several enzymes[2,3], some of which have been localized in hair follicles by histochemical methods[4,5]. Very little investigation of enzymes concerned with protein metabolism in the hair follicle has been made, despite the fact that protein synthesis is the major activity of this tissue.

The demonstration of free α-amino- and α-oxo-acids in wool roots led Ellis, Gillespie and Lindley[2] to suggest that enzymes could be present which participate in the tricarboxylic acid cycle as well as in transamination reactions. In the present work transaminase activity has been demonstrated. In addition it has been found that another enzyme commonly found in tissues actively engaged in protein synthesis is present, namely, transpeptidase[6,7].

A homogenate was prepared by macerating 5 gm. wool roots with 50 ml. water in a Waring blendor, filtering through coarse 'Terylene' cloth, centrifuging at 2,000g and dialysing the supernatant against 0·02 M phosphate buffer pH 7·4 overnight at +2° C. The supernatant was more satisfactory to use than the original homogenate because of the difficulty of removing the endogenous amino acids from the latter.

The systems used were:

(*a*) For transamination: 0·7 ml. reaction mixture containing 0·5 ml. extract or 0·02 M phosphate buffer pH 7·4, 5 μgm. pyridoxal phosphate, 20 μmoles α-oxo-acid and 20 μmoles L-amino-acid; incubated for 2 hr. at 37° C.

(*b*) For transpeptidation: 0·6 ml. reaction mixture containing 0·5 ml. extract or 0·02 M phosphate buffer pH 7·4, 20 μmoles amino-acid (or water), and 2 μmoles neutralized glutathione; incubated for 30 min. at 30° C.

(*c*) For citrulline iminase: (1) 1·0 ml. reaction mixture containing 0·5 ml. extract, 5 μgm. pyridoxal phosphate, 0·02 M potassium dihydrogen phosphate, 15 μmoles L-citrulline, 20 μmoles magnesium chloride, 5 μmoles neutralized adenosine triphosphate, and 2 μmoles ammonium chloride; incubated for 30 min. at 37° C.; (2) as (1) with 0·05 M borate instead of potassium dihydrogen phosphate and 15 μmoles L-arginine instead of L-citrulline and without ammonium chloride.

Following incubation, the reactions were stopped by the addition of 1 ml. warm ethanol; in (*b*) the ethanol contained 2·2 μmoles N-ethyl maleimide. The clear supernatants were dried *in vacuo* and then applied to Whatman No. 1 paper; samples (*a*) and (*c*) were developed in 80 per cent aqueous phenol, and (*b*) in 80 per cent aqueous *n*-propanol for 24 and 240 hr. respectively.

So far it has been possible to demonstrate the formation of alanine from pyruvic and aspartic acids, and glutamic acid from α-oxoglutaric acid and alanine or citrulline. It is of interest that citrulline, which occurs in the free state in wool roots[8] as well as combined in the inner root sheath[9], participates in transamination.

It was not possible to obtain evidence of citrulline iminase activity[10]. This enzyme catalyses the reversible conversion of citrulline to arginine and has been suggested as a possible constituent of hair follicles[11].

Evidence for the presence of γ-glutamyl transferase activity[6,7] in wool root homogenates was found by the demonstration of the formation of γ-glutamyl glycine from glutathione and glycine. It is perhaps significant that Haurowitz *et al.*[12] have recently provided evidence for the occurrence of γ-glutamyl residues in wool and the present finding of transpeptidase activity could have relevance to their formation. In addition to transpeptidation, the chromatograms indicated that wool roots probably also possess peptidase and/or protease activity, although cysteinyl–glycinase[13] activity was weak or absent. This enzyme is usually found in conjunction with transpeptidase activity.

We wish to thank Dr. F. J. R. Hird for a gift of adenosine triphosphate, glutathione and α-oxoglutaric acid, Dr. A. W. Rodwell for pyridoxal phosphate and Miss C. M. M. Mackinnon for technical assistance.

Role of Lysine in catalysing Ester Hydrolysis

Recently, Gero and Withrow[1] have cited the catalysis of alkaline triglyceride hydrolysis by lysine as a chemical model of a biological reaction. They postulated a bifunctional[2] attack by lysine upon the carbonyl O and C of the ester linkage as the mechanism of this hydrolysis.

We believe that some objections can be made to their arguments for this mechanism. They have stated, "It stands to reason that the hydrogen bonds which the ε-ammonium group is to form with the carboxyl group of lysine and the O of the ester should be strongest when the N does not hold its hydrogens too tightly, because that is when they will be most readily donated for a hydrogen bond. Such would be the case just below the *p*H at which the ε-ammonium group of lysine loses a hydrogen and its positive charge. That happens at *p*H 9·5, so that lysine should be maximally active as a catalyst for ester hydrolysis around *p*H 8–9". The authors are clearly implying that N—H bond-strength is a function of *p*H. This, of course, is not the case. Instead, since they are describing the competition of several bases for protons, one would expect the usual arguments for acid-base equilibria to be applicable. In this case they are:

$$K_1 = \frac{[\epsilon NH_2]\ [R\text{—}\overset{\oplus OH}{\overset{\|}{C}}\text{—}OR']}{[\text{—}NH_3\oplus]\ [R\text{—}\overset{O}{\overset{\|}{C}}\text{—}OR']}$$

$$K_2 = \frac{[R\text{—}\overset{\oplus OH}{\overset{\|}{C}}\text{—}OR']}{[H\oplus]\ [R\text{—}\overset{O}{\overset{\|}{C}}\text{—}OR']}$$

$$K_3 = \frac{[\epsilon NH_2]\ [H\oplus]}{[\epsilon NH_3\oplus]}$$

Since K_3 has a value of $10^{-10\cdot53}$ for lysine[3] and K_2 should be about $10^{6\cdot0}$, depending upon the nature of the substituents of the carbonyl group[4], the concentration of the reacting species, $\text{—}NH_3+$ and $R\text{—}\overset{O}{\overset{\|}{C}}\text{—}OR'$, in the first equilibrium should be maximal and independent of *p*H over at least the *p*H range 4·0–9·5. Below the former *p*H the rate of ordinary acid hydrolysis and the protonation of the lysine carboxyl group would have to be taken into consideration. Consequently, the rate of the hydrolysis catalysed by lysine should be maximal and constant over this *p*H range. Inspection of their results does not show this to be the case. Instead the decrease of the hydrolysis rate with decreasing alkalinity below *p*H 8·6 is seen to follow closely the expected protonation of the α-amino group.

A further objection can be made to their choice of *p*H 8–9 as the range of maximal catalysis. The ε-ammonium group would not be expected to be appreciably dissociated below *p*H 9·5 since its *pK*$_A$ is 10·53. Catalysis then should not fall off below *p*H 9·0. Again, their results do not show this to be true.

Therefore it seems more likely to us that this is an example of general base catalysis similar to that reported for the imidazole group[5]. That is, the picture of bifunctional catalysis shown in Fig. 1 would be predicted.

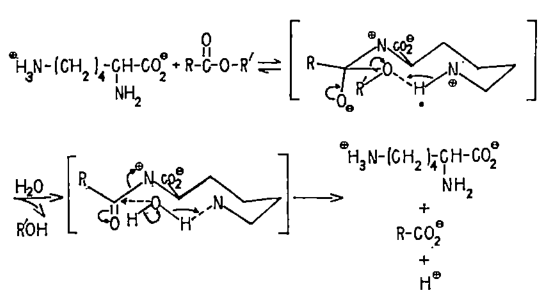

Fig. 1

An alternative to the second intermediate would be the co-ordination of a hydroxyl group by the ε-amino group into a position favouring its attack upon the carbonyl C. However, there is little to choose between the two possibilities.

Lysine as a ring structure as postulated by Gero and Withrow is sterically less suitable as a catalyst in this reaction sequence than it is in an open-chain form. Assumption of such a ring structure would be possible only with dissociation and loss of positive charge by the α-amino group, since it would otherwise require apposition of the two positive poles in the molecule. Consequently, the catalytic ability of lysine should decrease as the possibility for formation of ring structure increases above *p*H 8·95, the *pK*$_A$ of the α-amino group[3]. This is precisely what Gero and Withrow observed.

Consideration of the reaction sequence postulated above suggests that lysine should be very reactive with aldoses (in the hemiacetal configuration) since it is in good agreement with the mechanism deduced[6] for the Maillard reaction of amino-acids with aldoses. Inspection of the literature[7-9] shows that lysine is indeed particularly reactive with aldoses over the expected *p*H range, 7·0–9·5.

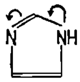
[9] Sentheshanmuganathan, S., and Hoover, A. A., *Biochem. J.*, **63**, 621 (1958).

In their criticism of our paper[1], Chesbro and Hedrick make some points that are indeed well taken. Their objection to the implication that bond-strength is a function of *p*H is undoubtedly valid. However, the statement they quote from our paper does not imply such a functional relationship. Rather, we had in mind the stretching of the N—H bond which may be expected to occur before the bond breaks (more so the more alkaline the environment) and which certainly will allow the proton to function more effectively as an acidic catalyst. It is regretted that for the sake of brevity we were not explicit enough to forestall a mistaken implication.

Chesbro and Hedrick's objections to our writing of lysine as a chelate ring and their alternative mechanism for lysine-catalysed ester hydrolysis strike us as less convincing. They state that a hydrogen bond between the carboxyl group and the ε-amino group of lysine can be formed "only with dissociation and loss of positive charge by the α-amino group, since it would otherwise require apposition of the two positive poles in the molecule". It is not apparent where the apposition of two positive poles occurs when in the chelate structure the two poles are separated by a chain of three atoms, one of them a negatively charged oxygen atom. As to their catalytic mechanism, which is an adaptation of the mechanism proposed by Bender and Turnquest[2] for ester hydrolysis catalysed by imidazole, it must be observed that in Bender's mechanism imidazole functions as a basic catalyst by virtue of the electron richness of its tertiary nitrogen :



Whether the reasoning based on the catalytic potency of the tertiary nitrogen in imidazole can be fitted without further ado to the α-amino group of an amino-acid, even with the auxiliary role which Chesbro and Hedrick assign to the ε-amino group, remains to be seen. Certainly, if their reasoning is correct, there should be at least some catalysis even by a simple amino-acid such as glycine, and this we found not to be the case. Also, if we are dealing, as Chesbro and Hedrick suggest, simply with general base catalysis similar to that reported for the imidazole group, one would expect histidine, which contains both an α-amino group and an imidazole ring, to be a more potent catalyst of ester hydrolysis than lysine. As reported in our communication, we found the reverse to be the case.

However, it is probably of minor importance which particular mechanism will eventually be accepted to interpret our findings. It is significant, in my view, that on general chemical grounds a prediction was made regarding a biological reaction and that the prediction was verified by experiment.

ALEXANDER GERO

Synthesis of Adenylosuccinic Acid in Preparations of Mammalian Skeletal Muscle

FROM the observation that the nitrogen-15 of labelled ammonium citrate administered to rats appears in the 6–NH_2 group of the muscle adenine nucleotides, Kalckar and Rittenberg[1] have concluded that the nucleotides take part in very rapid reversible de-amination reactions. That ammonium citrate nitrogen is similarly incorporated into rabbit skeletal muscle has been confirmed by Newton and Perry[2]. They have further demonstrated that aspartic acid is a more active donor of the 6–NH_2 group and that the enzymic activity is concentrated in the sarcoplasmic fraction of muscle.

Although the rapid reactions involved in the dephosphorylation and subsequent de-amination of adenine nucleotides to inosine nucleotides in muscle have been well established[3], little is known concerning the processes whereby the inosine nucleotides are re-aminated. The re-amination of inosine monophosphate by its condensation with aspartic acid to form adenylosuccinic acid occurs in preparations of rabbit bone marrow, whereas in muscle extracts an accumulation of adenine nucleotides has been reported to occur in the presence of inosine monophosphate with either aspartic acid[2] or creatine[4]. Although adenosine monophosphate, together with fumaric acid, is formed from the splitting of adenylosuccinic acid in water-soluble extracts of *Escherichia coli*, strain *B*[5], it is unlikely that in muscle the adenine nucleotides are resynthesized in this manner. The product of this reaction, adenosine monophosphate, has not been identified in skeletal muscle, and if formed, would be lost to the adenine nucleotide pool by its rapid and irreversible de-amination to inosine monophosphate by muscle adenosine monophosphate deaminase[6–8].

In the present work, adenylosuccinic acid was found to be formed from inosine monophosphate and aspartic acid in extracts of acetone-dried powder of the water-soluble fraction of rabbit and beef skeletal muscle. The reaction requires the presence of guanosine triphosphate, a very low concentration of which (0·01–0·02 m*M*), together with adenosine triphosphate (5 m*M*), is effective in causing the condensation, although adenosine triphosphate alone is not. During the course of the reaction adenosine triphosphate breaks down to the diphosphate apparently by rephosphorylating guanosine diphosphate—in the presence of a nucleoside diphosphate phosphokinase—to guanosine triphosphate, the splitting of which supplies the necessary free energy for the formation of adenylosuccinic acid. If adenosine triphosphate is used to rephosphorylate guanosine diphosphate formed during the reaction, 50–55 per cent of the inosine monophosphate is converted to adenylosuccinic acid. If traces of both guanosine triphosphate and adenosine triphosphate are used, in the presence of a glycolysing system for regenerating the latter from adenosine diphosphate, 90–100 per cent condensation of inosine monophosphate with aspartic acid is attained after 3-hr. incubation at 37°.

Fig. 1 shows the formation of adenylosuccinic acid in both undialysed and well-dialysed (2 days against 0·04 *M* potassium chloride) extracts of acetone-dried powder of rabbit skeletal muscle, in a reaction mixture containing 6 m*M* aspartic acid, 2·5 m*M* inosine monophosphate, 3 m*M* magnesium chloride, 4 m*M* fructose-1 : 6-diphosphate, 0·2 m*M* diphosphopyridine nucleotide, 50 m*M*, *p*H 6·9 glyoxaline buffer and 0·7 per cent protein solution. The course of the reaction was followed from the spectral change occurring as inosine monophosphate ($\lambda_{max.}$, 248 mμ) is converted to adenylosuccinic acid ($\lambda_{max.}$, 267 mμ). The triphosphates of uridine, cytidine, inosine (0·09 m*M*), and of adenosine (0·2 m*M*) could not replace the requirement for guanosine triphosphate, which increases the enzymic activity of the dialysed extracts to that of the undialysed extracts. The guanosine triphosphate is bound presumably to the enzyme causing the condensation, and is only released on exhaustive and prolonged

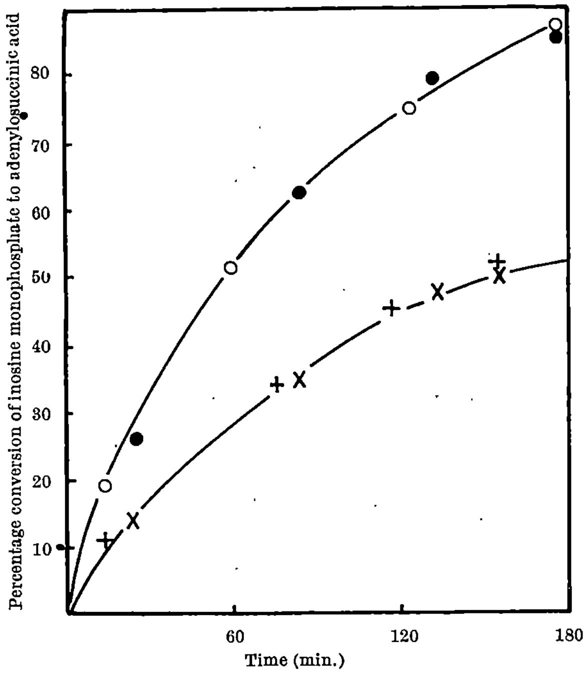

Fig. 1. The formation of adenylosuccinic acid from inosine monophosphate and aspartic acid, in undialysed extracts of rabbit muscle acetone-dried powder containing 0·005 mM adenosine triphosphate (●—●), in dialysed extracts containing 0·09 mM guanosine triphosphate and 0·005 mM adenosine triphosphate (○—○), in dialysed extracts containing 0·2 mM adenosine triphosphate (+—+) and in dialysed extracts containing 0·005 mM adenosine triphosphate with and without the triphosphates (0·09 mM) of uridine cytidine or inosine (×—×)

dialysis against 0·04 M potassium chloride at 0° for 8 days, by which time the enzymic activity is reduced by as much as 90 per cent. If such preparations are incubated with guanosine triphosphate and magnesium ions, and are then further dialysed for sufficient time to remove unbound guanosine triphosphate and magnesium, the activity is considerably greater than if the incubation before dialysis is carried out with guanosine triphosphate alone. The binding is apparently in the form of a complex of the enzyme, magnesium and guanosine triphosphate, in which form the enzyme is active.

The pH optimum of the condensation reaction is between pH 6·9 and 7·0. Inorganic phosphate in concentrations greater than 10 mM partially inhibits the reaction.

The significance of the adenine nucleotide de-aminating and re-aminating reactions in muscle is not known. If, as Kalckar and Rittenberg have suggested[1], the rates of these reactions increase with increase in muscular activity, it is possible that they play an important part in the process of muscular contraction.

Identification of 10-Hydroxy-Δ^2-decenoic Acid in Royal Jelly

Royal jelly[1] is the sole food administered by young workers or nurse bees of the common honey bee species *Apis mellifica* to female larvæ destined to become queens. Larvæ destined to become drones (males) or workers (sexually undeveloped females) receive royal jelly during the first three days of their existence only and then a different food. The components of royal jelly responsible for its remarkable properties remain unidentified.

Townsend and Lucas[2] recognized and Abbot and French[3] confirmed that an optically inactive acid $A(C_{10}H_{18}O_3)$ comprised the major portion of the ether-soluble fraction of royal jelly. We have identified A as 10-hydroxy-Δ^2-decenoic acid; royal jelly is the only known source of this compound. The acid A (m.p. 52° C. (found—C, 64·6; H, 9·4 per cent; equiv. wt., 187·9: calc. for $C_{10}H_{18}O_3$—C, 64·5; H, 9·7 per cent; equiv. wt. 186)) comprises approximately 70 per cent of the ether-soluble fraction and approximately 15 per cent of royal jelly. The infra-red spectrum (melt on rock salt) of A showed $\nu_{max.}$ at 3,480 cm.$^{-1}$ (hydroxyl), 1,710 cm.$^{-1}$ (carboxylic acid) and 1,667 cm.$^{-1}$ (unsaturation). Platinum catalysed[4] hydrogenation of A indicated the presence of one double bond and afforded 10-hydroxy-decanoic acid, m.p. 74° (found—C, 64·1; H, 10·9 per cent: calc. for $C_{10}H_{20}O_3$—C, 63·8; H, 10·7 per cent); Chuit and Hausser[5] quote a melting point of 75–76° for this acid. The identity of the saturated acid was confirmed by conversion to sebacic acid on permanganate oxidation and the linearity of the carbon chain in A thereby established.

The presence of $\alpha\beta$-unsaturation in A, indicated by strong end absorption in the ultra-violet was confirmed as follows. Oxidation of A with the periodate–permanganate reagent[6] which cleaves double bonds, gave suberic acid, but oxalic acid, the anticipated second reaction product, could not be detected; under the same reaction conditions, *trans*-crotonic acid gave oxalic acid. Hydroxylation[7] of A with osmium tetroxide gave a product B shown by paper chromatography[8] and ionophoresis[9] to contain a single component in addition to some starting material. Oxidation of B with the periodate permanganate reagent[5] gave oxalic acid as did D-tartaric acid, *meso*-tartaric acid and *erythro*-2 : 3-dihydroxybutyric acid. Reaction of B with periodic acid directly on Whatman No. 1 paper followed by chromatographic separation of the products gave glyoxylic acid identified as its 2 : 4-dinitrophenylhydrazone (m.p. 194–196° decomp.) after elution from the paper. When the preceding experiments were essentially complete, our attention was directed to a report by Butenandt and Rembold[10] identifying A as 10-hydroxy-Δ^2-decenoic acid. No chemical proof of $\alpha\beta$-unsaturation or olefinic configuration was presented.

The olefinic C—H out of plane bending in *trans*-compounds is characterized[11] by strong absorption near 980 cm.$^{-1}$ in the infra-red. Both A and 10-hydroxy-decanoic acid absorbed near this value (987 and 981 cm.$^{-1}$ respectively) probably due to C—O stretching. Sheppard and Simpson[12] have observed a strong absorption in the range 675–725 cm.$^{-1}$ for a series of *cis*-olefins; but Allan, Meakins and Whiting[11] have assigned the absorption near 820 cm.$^{-1}$ to the olefinic C—H out of plane bending in *cis*-$\alpha\beta$-unsaturated acids and esters. A and its methyl ester show moderately strong absorption in the range 675–725 cm.$^{-1}$ whereas 10-hydroxy-decanoic acid does not. However, *trans*-crotonic acid and its methyl ester also absorb in this range. While the methyl ester of *A* shows no absorption near 820 cm.$^{-1}$ both *A* and 10-hydroxy-decanoic acid show weak absorption at 817 and 823 cm.$^{-1}$ respectively. Thus, on this basis, the configuration of the olefinic linkage in *A* cannot be allocated with certainty.

The biological origin of 10-hydroxy-Δ^2-decenoic acid has not been established. It is not present in the free state in nectar (collected from the hive), honey, or pollen of a representative monocotyledon (*Zea mays*), dicotyledon (*Alnus glutinosa*) and conifer (*Pinus montana*). The acid may be present in combined form or it may be a specific bee product.

10-Hydroxy-Δ^2-decenoic acid showed little activity against a representative range of bacteria and fungi; weak activity against strains of *Streptococcus pyogenes* and *Tricophyton rubrum* was displayed.

We thank Prof. M. Stacey for his interest in this work and Messrs. Glaxo, Ltd., for the biological activity assays.

Effect of Reduced Diphosphopyridine Nucleotide on the Swelling of Isolated Mitochondria

It has been repeatedly reported that isolated mitochondria maintain a low water content if incubated in conditions favourable to oxidative phosphorylation[1–5]. Di Sabato and Fonnesu[6,7] found that this happens only when certain metabolites are used as the oxidizable substrate, for example, succinate, α-ketoglutarate and glutamate.

This communication deals with a study on the effect of reduced diphosphopyridine nucleotide on the swelling of the mitochondria in both conditions favourable and unfavourable to oxidative phosphorylation.

The preparation and incubation of mitochondria from rat liver, and the estimation of the swelling by the optical method were carried out as already described[6,7], with the difference that the readings of optical density were taken at 950 mμ. In order to establish whether reduced diphosphopyridine nucleotide is oxidized or not, soon after every reading at 950 mμ, the optical density of the mitochondrial suspension was measured at 340 mμ.

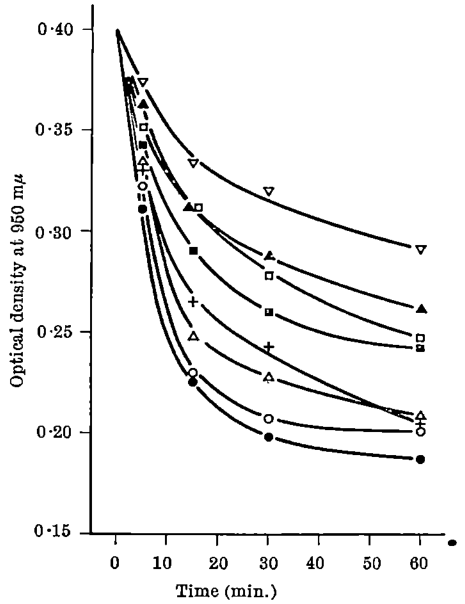

Fig. 1. Effect on mitochondrial swelling of various added substances: (1) +, control; (2) △, reduced diphosphopyridine nucleotide; (3) ○, cytochrome *c*; (4), ●, (2) + (3); (5) ▲, (2) + adenosine monophosphate; (6) ■, (5) + (3); (7) □, (3) + adenosine monophosphate; (8) ▽, (5) + 2,4-dinitrophenol

The composition of the standard incubation medium employed was as follows: magnesium sulphate, 30 μmoles; potassium phosphate buffer, *p*H 7·2, 60 μmoles; sucrose, 690 μmoles. The additions (Fig. 1) were: adenosine-5′-monophosphate, 180 μmoles; reduced diphosphopyridine nucleotide (Sigma Chemical Co.; 90–95 per cent purity), 6 μmoles; cytochrome *c*, 0·06 μmole; 2,4-dinitrophenol, 0·6 μmole; oxidized diphosphopyridine nucleotide, 6 μmoles. The final volume, after the addition of the mitochondria, was 6 ml.

Fig. 1 shows the rate of the mitochondrial swelling in the presence of various added substances. It is apparent that reduced diphosphopyridine nucleotide alone slightly enhances the 'spontaneous' swelling of mitochondria, but, at the end of the incubation, the swelling is nearly the same as that in the control. One can also see that cytochrome *c* alone enhances the mitochondrial swelling a little more than reduced diphosphopyridine nucleotide. When the mitochondria are incubated in the presence of both these substances, the swelling is greater than in the presence of either of them separately. When the mitochondria are incubated in conditions favourable to oxidative phosphorylation, that is, in media containing reduced diphosphopyridine nucleotide and adenosine monophosphate or these substances together with cytochrome *c*, the spontaneous swelling is partially prevented. This phenomenon, however, seems to be due to the action of adenosine monophosphate, since it was also observed with cytochrome *c* + adenosine monophosphate, as well as with adenosine monophosphate alone (not shown in Fig. 1; see refs. 7 and 8). That the protection from swelling in a system containing diphosphopyridine nucleotide and adenosine monophosphate is not due to the phosphorylation-coupled oxidation of the nucleotide, is also shown by the fact that the swelling is prevented rather than enhanced by the addition of 2,4-dinitrophenol.

Estimation of reduced diphosphopyridine nucleotide during the incubation showed that, in the absence of cytochrome *c*, almost 70 per cent of that added is oxidized in the first 30 min. The added cytochrome *c* enhances the rate of oxidation only slightly; on the other hand, greater amounts of cytochrome *c* have not been used, since, as reported above, this substance promotes mitochrondrial swelling.

In an attempt to elucidate whether the behaviour of the mitochondria is due to the oxidized diphosphopyridine nucleotide that is formed, experiments were carried out using the oxidized in place of the reduced form. The results of these experiments, not reported fully here for the sake of brevity, showed that the oxidized form is almost without effect on the mitochondrial swelling.

The most important fact arising from these experiments is that mitochondria are better protected from swelling in a medium unfavourable to oxidative phosphorylation than in one favourable to oxidative phosphorylation. This confirms once more that high-energy phosphate bonds are not essential for maintaining the mitochondria in the contracted state.

Differences in Cyst(e)ine Content between Vegetative Cells and Spores of *Bacillus cereus* and *Bacillus megaterium*

IN the course of investigations on the role of sulphur amino-acids in the sporulation process of bacilli we studied the inhibitory effect of a large excess of cystine (10^{-4} *M*) on spore formation in *Bacillus megaterium*[1], and the incorporation of cystine-^{35}S and methionine-^{35}S, added in small quantities to the nutrient medium before sporulation, into sporulating cells of inhibited and of control culture[2]. The control culture, which was pre-adapted to cystine and treated with cystine just before sporulation, during sporulation incorporated considerable quantities of ^{35}S-amino-acids added at the time to the nutrient medium. During the 'cystine inhibition' the spore formation of *B. megaterium* remained for a long time in the first stage and the incorporation of labelled amino-acids was markedly lower.

Cultivating *B. megaterium* in the presence of ^{35}S-amino-acids from inoculation, we found that the free spores contained significantly more radioactive sulphur than the vegetative cells before spore formation[2]. With regard to the possibility of different cyst(e)ine contents of the vegetative cells and of spores we started to investigate these differences in both forms of bacilli.

A strain of *Bacillus cereus* (N.C.I.B. 8122) and our laboratory strain of *Bacillus megaterium* were used. Either bacillus was cultivated on a shaker at 30° C. in a liquid medium containing tryptic casein hydrolysate, 0·3 per cent; glucose, 0·1 per cent; phosphates and traces of some important ions. Cystine was added to the medium to give a concentration of 10^{-4} *M* before inoculation. The cells were harvested in order to estimate the cyst(e)ine after 12 hr. of cultivation, that is, about 2 hr. before spore formation; and after 100 hr. of cultivation, after complete liberation of spores and autolysis of the debris of sporangia. The harvested cells were killed with 10 per cent trichloracetic acid, washed, extracted with ethanol–ether (3 : 1) and heated in 5 per cent trichloracetic acid at 90° C. for 30 min. The precipitate, the fraction insoluble in hot trichloracetic acid, obtained in this way was used for the determination of cyst(e)ine content.

For the estimation of cyst(e)ine a specific method developed by Akabori[3] was used, involving reductive decomposition of proteins by hydrazine at 120° C. Hydrogen sulphide produced from both cystine and cysteine is driven out by acidification of the hydrazine with sulphuric acid and absorbed in zinc acetate solution. The zinc sulphide is estimated by the Carius method using dimethyl-*p*-phenylenediamine[4]. The nitrogen content of the precipitate was determined by the usual Kjeldahl method.

The results shown in Fig. 1 indicate that the spores of *Bacillus cereus* and *Bacillus megaterium* contain significantly more cyst(e)ine (about five times) than the vegetative cells before spore formation. This supports the hypothesis that the protein structure of spores differs substantially from that of vegetative cells. It is known that cystine, with its SS-bridges, plays an important part in the structure of some highly inert proteins, for example, keratins. A possible analogy with the structure of spores cannot be excluded. Stabilization of their protein structure

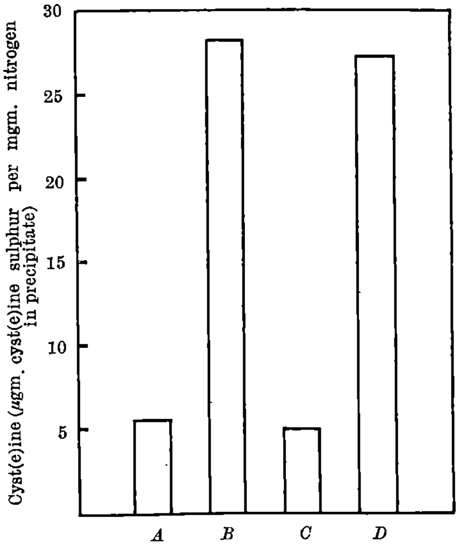

Fig. 1. The cyst(e)ine content of vegetative cells and of spores of *Bacillus megaterium* and *Bacillus cereus*. *A*, Vegetative cells; *B*, free spores of *B. megaterium*; *C*, vegetative cells; *D*, free spores of *B. cereus*

by SS-bridges may be a further mechanism contributing to the resistance of resting spores. Further details of the participation of cystine in spore formation will be described elsewhere.

PHYSICAL SCIENCES

Thin Magnetic Films

THE preparation of thin films of magnetic alloys with specific characteristics is generally acknowledged to be a difficult task, owing to the large number of parameters involved. One such parameter, that of film thickness, might be expected to have a large effect on magnetic characteristics. The relation between this and coercivity has been studied theoretically by L. Néel[1], for film thicknesses in excess of domain wall thickness. For this condition, small variations in the thickness of the layer give rise to energy changes as domain walls are moved and lead to the relation $H_c \propto t^{-4/3}$, where H_c is the coercivity and t the average thickness. Tiller and Clark[2] have found $H_c \propto t^{-1}$ experimentally for t varying from about 250 A. to nearly 2,800 A.

To investigate this dependence more fully, an apparatus (Fig. 1) has been developed which allows the low-frequency hysteresis loop to be monitored both during deposition of the film and afterwards. The base, 1, on to which the magnetic alloy, 2, is to be evaporated is supported at the top of a flat-topped bell-jar, 3, The alloy is heated by induction from the coil, 4, and a shutter, 5, stops deposition on to the base, 1, until the alloy is evaporating freely. A Helmholtz coil, 6, produces an alternating aligning field of approximately 30 oersteds in the plane of the base, 1. Frequencies up to 1,000 c./s. have been tried, but generally 50 c./s. is used. The sensing coil, 7, consists of two rectangular windings each of 1,800 turns, with dimensions 2 in. × 1 in. The windings are connected so that the flux linkages with the evaporated specimen are additive, and are each adjusted slightly from the horizontal plane, so that the total flux linkage with the alternating aligning field is zero. Usually a small voltage is induced into the sensing coil from 50 c./s. eddy currents in metal components of the assembly and this requires separate cancellation. The output voltage from the sensing coil is thus proportional to $\dot{\varphi}$, where φ is the flux in the magnetic layer. The voltage is integrated and amplified, and a vertical deflexion proportional to φ is presented on an oscilloscope tube. The horizontal deflexion is derived by conventional means from the alternating current flowing in the Helmholtz coil. The base, 1, has generally been maintained at an elevated temperature during deposition by means of toroidally wound d.c. heaters, 8, applied to the outside of the bell jar, the magnetic field from which is negligible. The sensitivity of the apparatus as described is such that a recognizable hysteresis loop is obtained when the thickness of the layer is about 150 A., and no attempt has been made to improve upon this figure, so far.

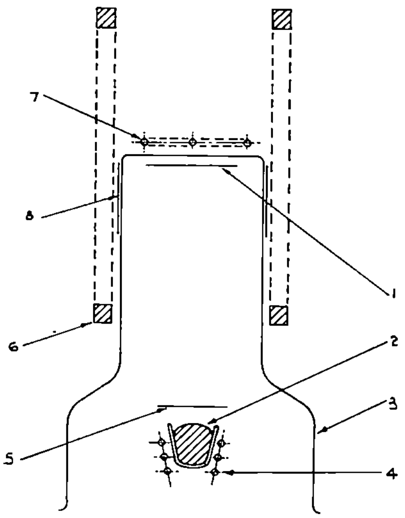

Fig. 1

Nearly two hundred evaporations have been made using the apparatus, the majority using lime soda glass for the base, 1. Substratum temperatures have ranged from 250° to 400° C., and alloy compositions from 75 per cent nickel, 25 per cent iron to 85 per cent nickel, 15 per cent iron. In the great majority of evaporations the coercivity changes little as the thickness varies from 150 A. to 1,500 A. If the evaporation is then continued up to 10,000 A., either a steady decrease of coercivity from its initial value of 1–2 oersteds to about 0·5 oersted is seen, or a sudden increase to 10–20 oersteds occurs at a thickness of about 2,000 A. The rapid increase in coercivity appears to be associated with atomic arrangement within the layer, since it continues for several seconds if the vapour stream is terminated during the increase with the shutter, 5. Moreover, the coercivity of such a layer can be reduced to 1–2 oersteds by annealing at 350–400° C. in a magnetic field. Occasionally, the coercivity first seen is in the region of 10 oersteds, decreasing to 1 or 2 oersteds at a thickness of about 300 A., and thereafter remaining constant up to about 1,500 A. Very rarely the coercivity has been seen to increase slightly as the thickness increases from 150 to 1,500 A. On other substrata, the behaviour of the coercivity during deposition may be markedly different from the above. If the glass is coated with aluminium a few hundred angstroms thick, for example, which is then oxidized, an initial coercivity of 10–20 oersteds, steadily decreasing during deposition to a value of 1–5 oersteds at a thickness of about 1,500 A. has been found. This behaviour is more like that observed by Tiller and Clark.

The apparatus has also been used to monitor a small number of films electroplated on to a copper base. In these experiments a behaviour similar to that described for the evaporation on to aluminium oxide was obtained.

The use of an alternating aligning field which has a zero value twice in each cycle is perhaps questionable. As, for a similar set of conditions, nearly all specimens exhibit a distinct pattern of magnetic behaviour during deposition, it seems rather unlikely that the variations observed can be attributed to the use of an alternating field. Certainly it is possible to produce magnetic specimens with a well-defined magnetic axis and a relaxation time of less than 200 millimicroseconds in an applied field of twice the coercive field.

These experiments show that the variation of the coercivity of thin films during formation is not a simple relation as given by Néel[1] but is influenced very strongly by secondary effects such as the nature of the substratum.

An apparatus similar to that described above has also been developed by K. E. Drangeid.

Examination of Particulate Matter on Filter Membranes

Fine filter membranes with maximum pore sizes less than 1μ are now readily available for collecting solid material suspended in a liquid. As the membranes are of very uniform thickness, they may be examined under a microscope for the determination of the sizes and nature of the particles deposited on them. We have used a simple and effective technique for preparing slides incorporating the sample membrane. The essential feature of the method is that the membrane is made transparent to permit the use of transmitted light without disturbing the particle distribution.

A water ejector pump is usually used to assist filtration. By keeping this running the membrane may be dried in a few minutes. With the suction still applied, a fixative is poured down the side of the filter funnel so as to spread steadily across the membrane and be drawn through it. The forces acting on the particles are such that these are held against the membrane and are not disturbed by the advancing liquid front. The fixing process is complete when the fixative has been drawn through the membrane and the latter is again dry.

With the correct choice of fixative the membrane retains its porosity, and is thus capable of being rendered transparent by saturation in Canada balsam diluted with xylene. It can be mounted as desired without fear of disturbing the particles. We have used a solution of 0·5 per cent (w) 'Perspex' in chloroform as the fixative, and found it to be eminently suited to our application.

Where an automatic particle counter is used care must be taken to choose a membrane exhibiting negligible grain when treated, and to ensure that the drying processes are carried to completion, otherwise blotches caused by trapped air or liquid other than balsam may result in counting-errors.

Refractivity and Lattice Constant Ratios of Lithium-6- and Lithium-7-rich Fluorides

The Industrial Group of the United Kingdom Atomic Energy Authority has provided small quantities of lithium compounds, containing different proportions of the isotopes lithium-6 and lithium-7, for use by its Research and Development Laboratories at Capenhurst.

Some of the material has been converted to lithium fluoride, and the refractivity of vacuum-grown crystals containing respectively (*A*) 90 per cent lithium-6, and (*B*) 95 per cent lithium-7, has been determined in the Natural Philosophy Department, Aberdeen, using a Hilger–Watts 'Research' pattern spectrometer, with 6·5 in. diameter glass circle. Prism *A* has faces 22 mm. × 26 mm., and prism *B*, 35 mm. × 26 mm. The observations were reduced to a uniform temperature of 21° C., and to standard atmospheric pressure.

Table 1. Variation of Refractive Index of Lithium Fluoride with Wave-length

λ (A.)	$n(A)$ (90 per cent lithium-6 fluoride)	$n(B)$ (95 per cent lithium-7 fluoride)	$n(N)$ (normal lithium fluoride).
4471·48	$1{\cdot}39618_{4(6)}$	$1{\cdot}39631_{2(4)}$	1·396310
5015·68	$1{\cdot}39414_{8(7)}$	$1{\cdot}39428_{6(4)}$	1·394289
5893·7	$1{\cdot}39189_{8(6)}$	$1{\cdot}39206_{2(7)}$	1·392066
6678·15	$1{\cdot}39049_{7(2)}$	$1{\cdot}39068_{5(3)}$	1·390683

Table 1 gives indices for four wave-lengths. Each value is the mean of three independent mean values, obtained from measurements on all three angles of the prism. The bracketed figures are the average residual errors ($\times 10^6$). The overall error was 5×10^{-6} for prism *A* and 4×10^{-6} for prism *B*. The last column, with values for the refractive index of normal lithium fluoride, is from measurements by Tilton and Plyler at the National Bureau of Standards[1].

Table 2. Variation with Wave-length of Refractive Index Differences

λ (A.)	$n(B) - n(A)$	$n(N) - n(A)$	$n(B) - n(N)$
4471·48	$12{\cdot}8 \times 10^{-5}$	$+ 12{\cdot}6 \times 10^{-5}$	$+ 0{\cdot}2 \times 10^{-5}$
5015·68	13·8	+ 14·1	− 0·3
5893·7	16·4	+ 16·8	− 0·4
6678·15	18·8	+ 18·6	+ 0·2

Table 2 shows the difference in refractivity between the enriched specimens *A* and *B*, and also between these and normal lithium fluoride. The major variation of 85 per cent in the proportion of lithium-7 from *A* to *B* produces an effect which varies from 13 to 19 $\times 10^{-5}$ in the range considered. Hence the difference of 2·4 per cent between *B* and normal lithium fluoride (92·6 lithium-7) should produce a shift of $n(B) - n(N)$ only ranging from 0·36 to $0{\cdot}53 \times 10^{-5}$ which is of the same order as the error. Moreover, Tilton and Plyler[1] found that there are small variations in the fifth decimal place between prisms of normal lithium fluoride, so that the close agreement shown in the last column between $n(B)$ and $n(N)$ is satisfactory.

The difference in refractivity increases with wave-length and can be fitted closely to an expression $x + y\lambda^2$. Using the least squares method, the values for $n(B) - n(A)$ are $x = 7{\cdot}723$, $y = 24{\cdot}83$ and for $n(B) - n(N)$, $x = 7{\cdot}870$, $y = 24{\cdot}60$. It is suggested that the term x arises primarily from the change in lattice constant, and the variable term from the change in infra-red dispersion frequency with the isotopic fraction.

X-ray measurements by Thewlis[2] show that the lattice constant of lithium-6 fluoride exceeds that of lithium-7 fluoride by 2×10^{-4} parts. This dilation would produce a reduction in refractivity of the order of 20×10^{-5}, were it not partially offset by a rise in the sum of the ionic polarizabilities. However, the net effect of expansion at constant composition is effectively displayed by the temperature coefficient (dn/dT) of normal lithium fluoride, which is $-1{\cdot}65 \times 10^{-5}$ at a mean wave-length in the visible region.

The linear expansion coefficient of lithium fluoride at 20° C. is $3{\cdot}44 \times 10^{-5}$ per deg. C., so that a temperature rise ΔT of about 5 deg. C. produces the same dilation of the lattice in normal lithium fluoride as the change in composition from B to A at constant temperature. The product of the equivalent temperature rise and the temperature coefficient (dn/dT) gives a term of the order of -8×10^{-5}, which is close to the observed values of x. Conversely, x may be used to estimate the lattice dilation, and Table 3 shows the equivalent temperature rise ΔT, the expansion ratio (da/a), the change Δf in the isotopic fraction, and the expansion ratio $(da/a)_{100}$ scaled linearly to a 100 per cent change in isotopic fraction. The mean value is $1{\cdot}94 \times 10^{-4}$, in close agreement with the X-ray value (2×10^{-4}).

Table 3. DATA FOR DERIVATION OF $(da/a)_{100}$

Data	x	ΔT	(da/a)	Δf (per cent)	$(da/a)_{100}$
$n(B)-n(A)$	7·723	4·77	$1{\cdot}64 \times 10^{-4}$	85	$1{\cdot}99 \times 10^{-4}$
$n(B)-n(N)$	7·870	4·68	$1{\cdot}61 \times 10^{-4}$	82·6	$1{\cdot}90 \times 10^{-4}$

The equivalent rise of temperature simulates the effect of an increased amount of lithium-6 at sufficiently high frequencies, but in the visible region there will be a further difference arising from the increase in infra-red dispersion frequency. The refractivity at 23·6° C. of normal lithium fluoride, from 0·4 to 5·9μ, has been represented[1] by a Ketteler–Helmholtz dispersion formula:

$$n^2 = 1 - \frac{5{\cdot}1281966\lambda^2}{797{\cdot}8925296 - \lambda^2} + \frac{0{\cdot}92556295\lambda^2}{\lambda^2 - 0{\cdot}0053160}$$

The second term is of the form $-\dfrac{a\lambda^2}{\lambda^2_R - \lambda^2}$, where λ_R is the effective infra-red dispersion wave-length. Thus a change $d\lambda_R$ with variation in composition will produce a change in refractive index:

$$dn \simeq \frac{a\lambda^2}{n\lambda^2_R}\left(\frac{d\lambda_R}{\lambda_R}\right)$$

which is of the required form $y_c\lambda^2$. Infra-red transmission and reflectivity measurements on materials A and B accord with the assumption that the product $m\lambda_R^{-2}$ is constant[3], where m is the reduced mass, so that the ratio $(d\lambda_R/\lambda_R) = 0{\cdot}0485$ for B and N, giving a calculated value $y_c = 22{\cdot}4$, in substantial agreement with the observed value $y = 24{\cdot}6$. For the B and A observations, the corresponding values are $y_c = 23{\cdot}1$ and $y = 24{\cdot}8$.

Thus the differences in refractivity are in close agreement with those predicted from existing X-ray, dispersion and expansion observations. Fig. 1 shows the variation of $n(B) - n(A)$ with wave-length; the full curve gives the computed values for a dilation $(da/a)_{100} = 2 \times 10^{-4}$, and for a ratio $(d\lambda_R/\lambda_R) = 1{\cdot}05$ appropriate to an 85 per cent change in composition. The residuals are less than $0{\cdot}4 \times 10^{-5}$.

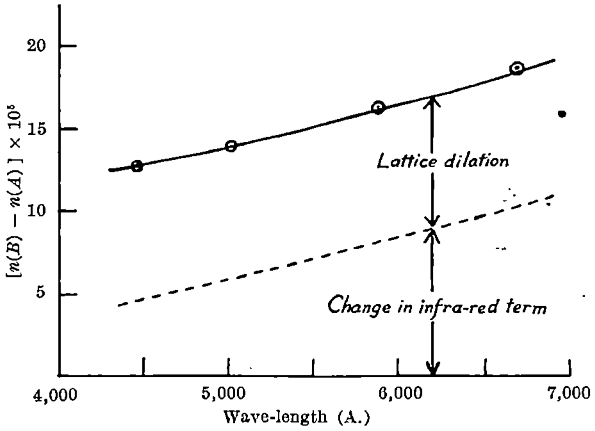

Fig. 1. Excess refractive index of lithium-7 fluoride-rich (B) over lithium-6 fluoride-rich (A) prism. The full curve is the theoretical excess for the observed lattice constant ratio $a(^6\text{LiF})/a(^7\text{LiF}) = 1{\cdot}0002$ and for the increase of 5 per cent in the infra-red dispersion frequency from B to A. The dashed curve is the change arising from the infra-red term alone

We thank the Ministry of Supply for a grant providing the crystal-growing facilities in the Natural Philosophy Department at Aberdeen, and the Chemical Services Department, Capenhurst Works, United Kingdom Atomic Energy Authority, for preparing and analysing the lithium fluoride.

We thank Mr. W. Mitchell for assistance in operating the furnace, and in preparation of the prism blanks, which were polished by Messrs. Barr and Stroud, Ltd., Glasgow.

Spacing Anomaly in Electron Microscope Images of Crystal Lattices

SINCE Menter's observation[1] on electron microscope images of crystal lattices of metal phthalocyanines, several authors[2-7] have observed a variety of lattices in this way. Interpreting the image in terms of the kinematic theory of electron diffraction and Abbe's theory of image formation, Menter concluded that it should consist of parallel lines with equal spacing. He measured[3] the spacings of many images of platinum phthalocyanine and concluded that their average value does in fact coincide with the spacing of the lattice planes. Uyeda *et al.*[8] suggested that an image of the superlattice spacing of about 90 A. observed in antigorite crystals is useful for checking the magnification of electron micrographs because of its constancy.

In analysing some moiré patterns[9] one of us (H. H.) found local spacing anomalies in the image, where the Bragg reflecting condition was not exactly satisfied.

Similar spacing anomalies have been detected in micrographs of crystal lattices of copper phthalocyanine, platinum phthalocyanine, zinc phthalocyanine and antigorite. A typical anomaly in an electron micrograph of copper phthalocyanine is shown in Fig. 1. The micrograph was cut into two parts perpendicular to the parallel lines of the image and the two parts have been juxtaposed to demonstrate the spacing anomaly clearly. The lines indicated by the arrows coincide with each other on both parts of the photograph ; but there are small relative displacements of the lines in between. The spacing of the weak lines is larger than that of the strong ones, and at the maximum the relative displacement is almost a quarter of the spacing. This type of spacing anomaly has been observed in other crystals associated with regions of different intensity in the line pattern and was found to move with the movement of the region of different intensity.

The anomaly may be explained by the dynamical theory of electron diffraction. When the angular setting of the crystal deviates slightly from the Bragg position, the wave vectors of the primary and reflected waves in the crystal change from those at the Bragg setting. Since the image is formed by the interference of primary and reflected waves, it may be expected that the image will vary with the deviation from the Bragg angle. Some calculations, reported in detail elsewhere, have been made on this basis where one Bragg reflexion only is excited, and these explain the anomaly satisfactorily.

The calculation shows that the lattice image of a plate-shaped crystal is composed of parallel lines, but the positions of the lines do not necessarily coincide with the positions of the potential maxima in the crystal, and, moreover, the contrast of the image changes both with the thickness of the crystal and the deviation from the Bragg angle. In a bent plate-shaped crystal the lattice image is formed only on the extinction contour. In the centre of the contour where the Bragg condition is satisfied exactly the spacing of the image is equal to that of the original lattice, but it deviates from this either by expansion or contraction near the edge where the Bragg condition is not exactly satisfied.

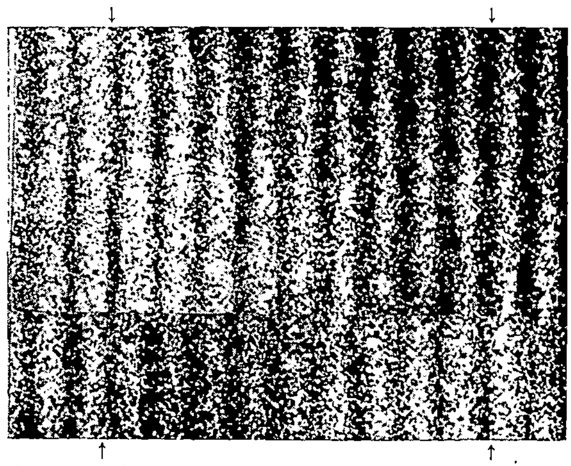

Fig. 1. Electron micrograph of crystal lattice of copper phthalocyanine with spacing anomaly. This can easily be detected by comparing the upper part with the lower part of the micrograph ; the micrograph has been divided into two parts by cutting across the image. The arrows indicate the positions where the corresponding lines coincide with each other on both parts of the micrograph

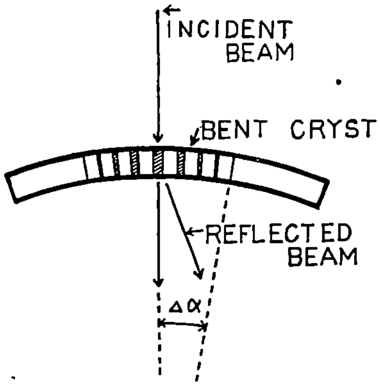

Fig. 2. Relation between the incident beam and uniformly bent crystal. Δα is an angle of bending

For example, if a crystal is bent into the form of a cylinder as shown in Fig. 2 and the thickness of the crystal is $t_0 = \lambda E/4V_g$ (where λ is wave-length, E is accelerating potential, V_g is the Fourier coefficient of the crystal potential, which is about 240 A. and 300 A. for the $20\bar{1}$ plane of copper phthalocyanine and platinum phthalocyanine respectively), the image in the centre of the extinction contour has the true spacing of the crystal lattice and maximum contrast, whereas near the edge of the contour the spacing is increased and the contrast lowered. If the thickness is $2t_0$ the image does not appear along the centre of the extinction contour but only at the brim with increased spacing. If the thickness is $3t_0$ the contrast of the image at the centre is reversed compared with that at t_0, that is, the positions of the lines shift by one-half spacing.

The thickness and mode of bending of the crystal shown in Fig. 1 are not known exactly, but it is estimated that the former is several hundred angstroms and the local bending can easily be larger than that corresponding to the angle $\Delta\alpha = 8 \times 10^{-3}$ rad. necessary to shift the image by one-quarter spacing. The calculation given above is therefore probably applicable to the present observation. It should be noted that the spacing anomaly may occur sometimes both as a result of bending and as a result of thickness variation across the crystal. It is concluded that the anomaly is not due to any anomaly in the crystal lattice spacing but arises from the dynamical effects in scattering of electrons by crystals.

We wish to express our sincere thanks to Prof. K. Tanaka and Prof. R. Uyeda for useful discussions.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, April 6

British Institution of Radio Engineers, Computer Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 3 p.m. and 6 p.m.—Symposium on "Large Capacity Storage Devices".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "Co-operation between the Electricity and Gas Industries" opened by Mr. F. C. Smith, M.B.E.

Society of Engineers (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. George Constantinesco: "Sonics".

Society of Chemical Industry, London Section (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Mr. W. A. M. Edwards: "Chemical Industry and the Free Trade Area".

Radar and Electronics Association (at the Royal Society of Arts, John Adam Street, Adelphi, London, W.C.2), at 7 p.m.—Dr. T. E. Allibone, F.R.S.: "Thermonuclear Research".

Monday, April 6—Wednesday, April 8

Society for General Microbiology (in the Beveridge Hall, Senate House, University of London, W.C.1)—Twenty-eighth General Meeting.

Monday, April 6—Friday, April 10

Fifth International Instrument Show (at 4 Tilney Street, Park Lane, London, W.1).

Tuesday, April 7

Physical Society, Acoustics Group (joint meeting with the Institute of Physics, in the Physics Department, The University, Southampton)—All-day Symposium on "New Techniques in the Analysis of Noise and Vibration".

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. M. E. Haine and Mr. J. Vine: "An Electron Trajectory Tracer for use with the Resistance Network Analogue".

Society of Chemical Industry, Plastics and Polymer Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Dr. J. Haslam and Mr. A. R. Jeffs: "Applications of Gas-Liquid Chromatography to the Work of a Plastics Analytical Department"; Mr. C. D. D'Oyly-Watkins, Mr. G. L. Palmer and Mr. C. M. Robertson: "Differential Thermal Analysis of some High Polymers".

Tuesday, April 7—Friday, April 17

Factory Equipment Exhibition (at Earls Court, London, S.W.5).*

Wednesday, April 8

Chemical Society (in the Large Hall, Friends House, Euston Road, London, N.W.1), at 10.30 a.m.—Prof. H. J. Emeléus, F.R.S.: "Some Inorganic Polymers" (Presidential Address).

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. L. Berry and Mr. B. P. Ruxton: "The Structure and Form of Hong Kong Harbour"; Dr. W. S. Pitcher and Prof. H. H. Read: "The Aureole of the Main Donegal Granite".

Institution of Mechanical Engineers, Internal Combustion Engine Group (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Discussion on "What is the Present Position of the Gas Turbine Relative to the Diesel Engine for Satisfactory Stationery, Marine and Automobile Applications".

Physical Society (in the Main Lecture Theatre, The Physiology Laboratory, The University, Oxford), at 8.30 p.m.—Prof. H. S. W. Massey, F.R.S.: "Collisions" (43rd Guthrie Lecture).*

Thursday, April 9

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Dr. Raymond Allchin: "The First Settlers in South India: Recent Research at Neolithic Sites in the Deccan".

Institute of Biology, London Branch (joint meeting with the Chelsea College of Science and Technology Biological and Geological Societies, at the Chelsea College of Science and Technology, Manresa Road, London, S.W.3), at 7 p.m.—Meeting on "Modern Ideas of Continental Drift". Speakers: Dr. J. A. Clegg and Dr. A. J. Cain.

Friday, April 10

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Prof. A. A. Mikhailov: "The Deflection of Light by the Sun's Gravitational Field" (George Darwin Memorial Lecture).

Medical Research Council (at the National Institute for Medical Research, Mill Hill, London, N.W.7), at 5 p.m.—Dr. S. E. Luria (Massachusetts Institute of Technology, Cambridge, Mass.): "Mechanisms of Infective Heredity in Bacteria".*

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Dr. W. B. Lewis: "Canadian Atomic Energy Development in Review and Prospect" (James Clayton Lecture).

Radar and Electronics Association (at Norwood Technical College, Knight's Hill, London, S.E.27), at 7 p.m.—Mr. D. C. Thomas: "A Modern British Marine Radar" (The B.T.H.601 "Escort").

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Psychologist (with an honours degree or equivalent qualification in psychology, and preferably postgraduate research experience in experimental or clinical psychology)—The Secretary, The National Hospital for Nervous Diseases, Queen Square, London, W.C.1 (April 10).

Plant Breeder (with an honours degree in botany and experience in plant breeding or a postgraduate qualification in genetics or plant breeding) in the Tea Research Institute of Ceylon—Dr. F. R. Tubbs, East Malling Research Station, near Maidstone, Kent (April 10).

Assistant Lecturer or Lecturer in Applied Mathematics—The Secretary, The University, Exeter (April 11).

Assistant Physicist (with an honours degree in physics and preferably some previous experience of hospital physics) in the Radiotherapeutic Centre, for duties concerned with a wide variety of applications of physics to clinical radiotherapy and other branches of medicine—The Secretary, Addenbrooke's Hospital, Cambridge (April 11).

Lecturer (with a special interest in stratigraphy) in Geology—The Secretary, The University, Edinburgh (April 11).

Lecturer (preferably with an interest in molecular weight measurement or nuclear magnetic resonance) in Physical Chemistry—The Secretary, The University, Aberdeen (April 15).

Lecturer (with a special knowledge of the strength of materials, or theory of machines, or applied thermodynamics) in Mechanical Engineering; and a Lecturer (with a special knowledge of applied aerodynamics and/or aircraft performance) in Aeronautical Engineering—The Principal, Coventry Technical College, Butts, Coventry (April 16).

Senior Lecturers, Lecturers, and Assistant Lecturers (honours graduates, preferably with research experience) in the Department of Physics—The Clerk to the Governors, Chelsea College of Science and Technology, Manresa Road, London, S.W.3 (April 18).

Assistant Lecturer in Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (April 20).

Lecturer in Archæology—The Secretary, The Queen's University, Belfast (April 20).

Superintendent of Laboratories in the Department of Chemistry—The Registrar, University College, Singleton Park, Swansea (April 20).

Fellow (honours graduate in some branch of chemistry, with some postgraduate research experience) in Protein Chemistry in the Division of Protein Chemistry, C.S.I.R.O., Parkville (near the University of Melbourne), to apply ultra-violet and visible spectrophotometry in studies of the chemistry of extracted wool proteins and related model compounds and to relate the findings to similar measurements on the intact fibre—The Chief Scientific Liaison Officer, Australian Scientific Liaison Office, Africa House, Kingsway, London, W.C.2, quoting Appointment No. 463/116 (April 25).

Lecturer in Inorganic Chemistry—The Registrar, University College of Wales, Aberystwyth (April 25).

Lecturer in the Department of Mathematics, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 25).

Lecturer (with qualifications in either chemistry or physics or glass technology) in the Department of Glass Technology—The Registrar, The University, Sheffield (April 25).

Lecturer (with special qualifications in fluid dynamics) in Mathematics—The Secretary of Faculties, University Registry, Oxford (April 25).

Lecturer in Philosophy—The Secretary, Balliol College, Oxford (April 30).

Research Fellow (with a Ph.D. degree or equivalent research experience in physical-organic chemistry or biochemistry) in the Chemistry Department, for an investigation of the mode of action of germicides—The Professor of Chemistry, The University, Hull (April 30).

Scientific Officer (with a good honours degree, preferably with postgraduate experience) in the Plant Pathology Department, to work on virus diseases of field crops—The Secretary, Rothamsted Experimental Station, Harpenden, Herts (April 30).

Assistant Lecturer (interested in plant physiology or the genetics of micro-organisms) in Botany; and an Assistant Lecturer in Psychology—The Registrar, The University, Hull (May 1).

Director of the Institute of Statistics—The Registrar, University Registry, Oxford (May 2).

Lecturer (with good academic qualifications and experience in one of the following fields: electrical power engineering, electrical engineering materials, or electrical engineering physics) in the Department of Electrical Engineering—The Registrar, The University, Leeds 2 (May 2).

Reader in Mechanical Engineering at Imperial College—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 6).

Lecturer in Pure Mathematics—The Secretary, The Queen's University, Belfast (May 8).

Chair of Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (May 9).

University Students or Fellows, for experimental or theoretical research in nuclear and elementary particle physics—The Professor of Natural Philosophy, The University, Glasgow, W.2 (May 9).

Chair of Education at University College, Ibadan, Nigeria—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 10).

Lecturer in Physics; and Lecturers (2) in Anatomy—Joint Clerk to the University Court, Queen's College (University of St. Andrews), Dundee (May 16).

Lecturer (preferably with an interest in histology and biochemistry) in Physiology—The Secretary of University Court, The University, Glasgow (May 16).

Assistants (either sex, with a good reading knowledge of Russian or Italian, and preferably with scientific interests), for abstracting papers in economic entomology—The Director, Commonwealth Institute of Entomology, 56 Queen's Gate, London, S.W.7.

Chief Plant Protection Officer (with a degree in entomology and considerable experience in economic entomology and plant quarantine services) in the Ministry of Agriculture and Lands, Jamaica, to direct and supervise the Plant Protection Division (including Entomology and Plant Pathology Sections), and to maintain an effective plant quarantine service—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/32/023.

Laboratory Technologist (Plant Pathologist) (with a university degree with botany as the main subject) in the Department of Agriculture, Kenya, to assist with laboratory research and field experiments in problems of coffee pathology and physiology—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/7/046.

Lecturer (with research and teaching experience) in Plant Physiology—The Professor of Plant Physiology, Imperial College of Science and Technology, Prince Consort Road, London, S.W.7.

Master (graduate) to teach Mathematics, Pure and Applied, up to Advanced Level—The Director of Studies, The Nautical College, Pangbourne, Berkshire.

Reader (with a good degree of a British university, research qualifications in some branch of applied mathematics or statistics, and preferably experience of teaching in a university or major technical college) in Applied Mathematics—The Clerk to the Governing Body, Battersea College of Technology, London, S.W.11.

Readers, Senior Lecturers and Lecturers in Chemistry, Electrical Engineering, Civil Engineering, Mechanical Engineering and Physics; and Senior Lecturers and Lecturers in Chemical Engineering, Metallurgy, Pharmaceutical Chemistry, Pharmaceutics, Pharmacology, Mathematics, Statistics and Zoology—The Registrar, Bradford Institute of Technology, Bradford 7.

Soil Surveyor (with a university degree, preferably with honours, in agricultural chemistry or pure chemistry, or, alternatively a degree in geology or geography, and a good knowledge of chemistry) in British Guiana, for soil surveys on the coastlands and the underdeveloped interior—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/30/017.

EXPANSION OF MARINE RESEARCH IN THE UNITED STATES

THE National Academy of Sciences – National Research Council has issued a statement making known the conclusions of a Committee which was set up at the request of a number of Government agencies to review the progress and needs of marine science in the United States. The full report is promised in the near future. The main conclusions are encouraging because they show that many of the problems that have long been too large and perplexing to attract close attention are becoming more approachable and promising; they are also disturbing because they show that progress, though commendable, does not match growing needs for detailed information and understanding of the oceans.

The statement mentions the need for increased food supplies. The main factor leading to high fertility in the oceans is active mixing and upwelling from the deep layers, where nutrients are regenerated, to the illuminated surface layer where the plants grow. Upwelling is not confined to coastal regions, or to oceanic islands and shoals, and it can occur wherever there are sharp differences and changes in the surface and sub-surface currents. Such areas, far from land, are already forming the basis of ocean fisheries, and the factory ships that will fish them will need good understanding of the fundamental physics and biology as well as the breeding, feeding and migratory habits of the fish to ensure economical working with regular catches.

The need for more understanding of fluctuations and trends in climate is also emphasized. The heat capacity of the oceans is very much larger than that of the atmosphere, and the oceans are largely responsible for the thermostatic control that makes so much of the Earth habitable. They gather the Sun's heat and distribute it as moisture-laden air in a pattern determined by complex interaction between sea and air, currents and winds. The slow but powerful changes in the oceans have important effects on agriculture, fisheries, ice conditions and sea-level. All the great hurricanes and typhoons start over the sea.

Modern studies of waves, tides, currents and movements of sediments have much to offer to ship designers, coastal and harbour engineers, and to those concerned with special aspects of navigation, salvage and oil drilling. The National Academy Committee, however, gives special emphasis to the needs of military defence. With every fresh advance in surface, amphibious and undersea warfare, the side with the fullest knowledge and most detailed understanding of the oceans is likely to gain some advantage in devising new techniques, discarding out-of-date ones and judging how to proceed. The report mentions the submarine menace and maintains that "from the point of view of military operations there is no comparison between the urgencies of the problems of the oceans and those of outer space". Concern that the new fascination of space will divert American scientists and the Government from the vast unexplored regions and problems of the oceans is implied throughout the statement.

The study of the sea floor has made tremendous strides during the past five years. With the help of new tuning-fork controlled echo-sounders the floor of the deep ocean can be charted in nearly as much detail as a river estuary, and the half-inch to a mile maps, photographs, cores and dredges reveal fascinating new information about active movements of water and sediment, eroded channels, possible mineral resources and the habits of bottom-living animals. The time has come when geology can be actively extended to the rocks and sediments at the bottom of the oceans.

The main recommendations of the Committee are that basic research in marine science should be doubled within the next ten years, and that the research effort should be supplemented by ocean-wide surveys. The resources of the present surveying effort, mainly that of the U.S. Coast and Geodetic Survey, would be doubled for the purpose. The whole programme would be strengthened by expanded application of the science to military defence, marine resources and the problems raised by the use of nuclear energy.

The first step towards the Committee's objective is the provision of new ships with the character of floating laboratories, and others for survey. The need for new devices such as submarines, mid-ocean platforms and unmanned buoys is emphasized, and new instruments and telemetering equipment are needed. It is estimated that each ship needs sixty hore-based scientists and technicians, and the difficulty of attracting men with the essential skill and enthusiasm is clearly recognized as the greatest difficulty.

Oceanography is no longer a descriptive subject; some of its theoretical and practical work is as advanced, as difficult and as likely to find useful applications in other sciences, as that done in any research laboratory. The subject has begun to attract attention in universities, especially in the United States, and the Committee feels that its difficulties may be surmounted by more deliberate measures to encourage interchange with universities. There can be no subject of wider and more rapidly growing interest or of more potential world value, and yet there is a shortage of qualified postgraduate research workers because the specialized facilities that might be used to continue university training are not used to the full, and the universities have few of their own. This problem will become more acute as the work in progress outside the universities requires increasing numbers of workers with more and more specialized qualifications; to solve it the Committee advocates affiliation of oceanographic research institutions with university faculties, and the development of new centres at universities.

The Committee proposes a ten-year plan costing 651 million dollars over and above the present level of expenditure. The plan is described as 'minimal' to meet long-range requirements, and it is stated that action on a scale appreciably less "will jeopardize the position of oceanography in the United States relative to the position of the science in other major nations, thereby accentuating serious military and political dangers, and placing the nation at a disadvantage in the future use of the resources of the sea".

The report has no official Government approval, but opinion in the United States expects it to guide the course of national support for marine science. Oceanographic research has already been earmarked by the President's Science Advisory Committee as one of the major scientific fields needing more emphasis. Further afield it is also of interest. From its very nature, oceanography is dependent on, and contributes to, most of the other sciences; moreover, its pursuit involves international collaboration on an extensive scale. Any increased support in the United States for oceanography will contribute to the development of the science and set an example which other countries might well follow.

EARLY AMERICAN NATURALISTS

John and William Bartram's America

Selections from the Writing of the Philadelphia Naturalists. Edited with an Introduction by Helen Gere Cruickshank. Pp. xxii+418. (New York: The Devin-Adair Company, 1957.) 5 dollars.

The Travels of William Bartram

Edited with commentary and an annotated index by Francis Harper. Naturalist's edition. Pp. lxi+727+42 illustrations and facsimiles. (New Haven, Conn.: Yale University Press; London: Oxford University Press, 1958.) 68*s*. net.

THE Quakers John Bartram and his son William were two of America's leading naturalists throughout the eighteenth century—their combined lives cover a span of nearly one hundred and twenty-five years, from 1699 until 1823. Although they were primarily botanists, and John established the first botanic garden in America near Philadelphia about 1730, they were widely interested in all aspects of natural history. In their early days there were few books that could help them in classifying the numerous undescribed species that they found, but when a merchant friend in Philadelphia took some of John's collections and observations to Peter Collinson of London, who immediately appreciated their value, a correspondence was started that lasted nearly fifty years. As a result of John's friendship with Collinson he entered into correspondence with nearly all the naturalists of Europe, including Linnæus and Sir Hans Sloane, and was elected into the fellowship of the Royal Society, and appointed "Botanist to His Majesty for the Floridas".

Both the Bartrams travelled extensively in pursuit of their studies, venturing far beyond the scattered settlements of the outposts into Indian territory where they endured many discomforts and hardships and not a few dangers. In 1743, John accompanied an expedition to make a treaty of peace with the Iroquois and travelled north to Oswego on the shores of Lake Ontario, but his major explorations were made twenty years later in Florida, a region which made a deep impression upon both him and his son. Afterwards, William also spent five years travelling through the Carolinas, Georgia, and Florida, gathering specimens and recording his observations. John was brought up to farming and had very little schooling; although he kept diaries of his travels he did not publish them and they were incorporated into the accounts printed by other members of his expeditions. William Bartram, however, had a fluent pen, and in 1791 he published at Philadelphia his "Travels through North and South Carolina, Georgia, East and West Florida", which was at once reprinted in London and Dublin, and translated into several foreign languages. This book, containing most interesting topographical, anthropological and biological observations, reveals him as a delightful character, full of curiosity, sympathy, and an appreciation of wild Nature rare in those days when the age of elegance regarded everything remote from the centres of civilization as a dreadful wilderness full of savage and horrid prospects.

The first of the volumes under review is an anthology of writings by, and about, the Bartrams, and is an excellent introduction for the general reader to the works of these pioneers. "Although William was one of the foremost of the earliest generation of American writers on natural history and travel, his work has never been known and appreciated in America the way it was abroad." There is no longer any reason for the prophet to be without honour in his own country. The second book is very much more ambitious. It is a reprint of the first edition of William's travels with a long and interesting introduction by Francis Harper, and a valuable commentary identifying the places visited, and the plants and animals seen, based upon extensive journeys made over Bartram's trails and upon much literary research. There is also a copious annotated index, an interesting section of illustrations and a number of maps. William Bartram's narrative is a fascinating account of America nearly two hundred years ago, and Harper's faithful editing enhances its lustre.

L. HARRISON MATTHEWS

RUDIMENTARY GOVERNMENT

Tribes without Rulers

Studies in African Segmentary Systems. Edited by John Middleton and [the late] David Tait. Pp. xi+234. (London: Routledge and Kegan Paul, Ltd., 1958.) 28*s*. net.

SEGMENTARY political systems constitute one of two main types of indigenous political organization found in Africa. Unlike the centralized type, they have no forms of general tribal government vested in chiefs or courts of law or any other overriding authority. They are made up of a collection of mutually independent segments, most commonly based on descent, which maintain law and order among themselves by various forms of self-help, including often the feud, and by making use of kinship, local and ritual bonds. Tribes of this type were, in the 'thirties, frequently recalcitrant to the efforts of colonial governments to devise for them administrative patterns in line with the aims of indirect rule. A handicap here was the paucity of ethnographic information on African political institutions and the consequent inadequacy of theoretical understanding of how they worked.

A beginning was made in the systematic study of the subject when, in 1940, Prof. Evans-Pritchard and I brought out a collection of essays describing a representative series of African political systems ("African Political Systems", edited by M. Fortes and E. E. Evans-Pritchard, 1940). The distinction between the centralized type and the segmentary type was there suggested. Post-war field research has so extended the range and quality of our ethnographic knowledge of Africa that this typology is now seen to be too broad. More thorough analysis of each type is now possible, and the present book makes a welcome beginning with this task. All the contributors belong to the post-war generation of social anthropologists. The six societies they deal with in the book were barely known before the Second World War. Certainly their indigenous political institutions could not then have been analysed with the technical proficiency and theoretical understanding shown by the editors and their fellow contributors.

The peoples described in the present book live in West Africa, the Sudan and East Africa. They vary from sedentary cultivators occupying clearly defined villages, like the Bwamba of Uganda, admirably described by Dr. Winter, to the transhumant cattle-keeping Dinka of the Sudan, whose complex social structure is skilfully elucidated by Dr. Lienhardt, and the widely dispersed, near-anarchic, Konkomba farmers and fighters of Ghana, described with great insight by the late Dr. David Tait, one of the editors. They differ widely in language, custom and belief. What they have in common is a segmentary political-structure based on some form of kinship and descent group.

In addition to the six essays, there is a valuable introduction by the editors. They demonstrate that the segmentary type really includes a range of varieties. They propose a division into three groups, an important distinction being the manner in which the genealogical and local segments are constituted and combined into what they call "jural communities". The analysis of the economic, military, juridical and religious sanctions correlated with this classification is particularly instructive. The book is a significant addition to the growing body of field research on non-western political institutions. It is also, as Prof. Evans-Pritchard remarks in his preface, a fitting memorial to Dr. Tait, who died in a motor accident before it was published. M. FORTES

SOLID STATE PHYSICS

Solid State Physics

By Prof. Adrianus J. Dekker. Pp. xiv+540. (London: Macmillan and Co., Ltd., 1958.) 45*s*. net.

IN recent years various text-books on solid state physics have been published, not without some influence on each other. At first sight, particularly with respect to selection of topics, Prof. Dekker's book bears a likeness to that of Kittel. However, more careful inspection reveals a different appreciation of the various aspects of the subject. There is evidence of the skilled teacher of modern physics with an awareness of the large range of mathematical ability among his student readers. The first nine chapters require little knowledge of the electronic characteristics of solids, beginning with a brief introduction to crystallography and moving all too rapidly through specific heats of solids, lattice defects, dislocation theory, dielectrics, ionic conduction and ferroelectricity. However, the presentation in each case is skilful enough to promote curiosity and wider reading in more specific texts. A further feature is the stressing of fundamentally important matters, for example the emphasis on the Debye theory of specific heats, though with proper indication of the more complex and, practically, almost unwieldly problem of lattice vibration spectra. To mention another chapter, that on ferroelectrics is lucidly written especially in the reference to the thermodynamic theory.

It is natural that the electronic properties of solids find a large place in this book. Non-polar crystals are emphasized, together with their applications in transistors. Complete chapters are devoted to luminescence and secondary electron emission, respectively, while the last part of the book deals with modern magnetism, inclusive of resonance phenomena and their importance in solid state research. If one looks for faults, and these are few, I feel that omission of dielectric breakdown might be remedied in the future and there might also be afforded a little more space for treatment of types of binding in solids.

Each chapter carries a number of exercises or problems; there are an adequate subject index and some useful appendixes. One more favourable comment must be added, about the surprisingly modest price of the volume compared with similar publications and with its equivalent price in the United States. G. F. J. GARLICK

NEW DRUGS USED BY PSYCHIATRISTS

The New Chemotherapy in Mental Illness

The History, Pharmacology and Clinical Experiences with Rauwolfia, Phenothiazine, Azacyclonol, Mephenesin, Hydroxyzine and Benactyzine Preparations. Edited by Dr. Hirsch L. Gordon. Pp. xviii+762. (New York: Philosophical Library, 1958.) 12 dollars.

THIS book is a collection of 119 articles by 167 authors, the majority of whom are American psychiatrists, relating their personal experiences with one or several of the new drugs used in mental illness. The individual writers address themselves to the practising physician and give their impressions, views, recommendations and warnings based either on the material they may have had at their disposal or on their personal philosophical outlook. This leads to statements so contradictory that they become rather disconcerting. Thus one author states on p. 99 that combined therapy with chlorpromazine and reserpine produces a prohibitively high incidence of serious untoward effects, whereas another worker assures us on p. 397 that this combination lacks toxicity and side effects, and he recommends it (p. 400) in neuropsychiatric treatment because of its "advantages over the use of either agent when employed alone". A third group of authors (p. 423) takes the intermediate view that the combination of the two drugs is probably not superior to the use of either drug alone, but that the toxic effects of larger doses are enhanced. That views on therapeutic successes are notoriously apt to be based on faith rather than on fact explains such contradictory opinions; yet methods of clinical trial are available nowadays which overcome these difficulties and yield reliable insight. A few carefully conducted trials, such as that described on p. 13 by H. A. Bowes who was trying to assess the value of azacyclonol ('Frenquel'), are more valuable than any number of uncontrolled clinical impressions. There are many valuable and well-founded observations in the book, but each article has to be scrutinized for the way in which the conclusions were reached before the reader can accept them as valid. The first seventh of the book contains articles of a somewhat more general nature than the later papers which relate clinical experiences only, but even in this section papers based on clinical impressions only are found side-by-side with others of a more objective nature.

If this book is to guide the practitioner through the labyrinth of neuropharmacology, care must be taken over nomenclature. The table on p. xvii is seriously misleading. Thus it suggests that 'Largactil', 'Megaphen' and 'Thorazine' are different compounds because it lists them alphabetically with other phenothiazines without revealing that they are identical. Even more confusing is the placing of 'Meratran' under the heading 'azacyclonol' and of meprobamate under the heading 'mephenesin', as this suggests that, for example, 'mephenesin' could be used as an alternative and more general name for meprobamate.

The main drugs covered by the book are shown in the title; more than 75 per cent of the material deals with reserpine and chlorpromazine.

Marthe Vogt

SOVIET PSYCHOLOGY

Psychology in the Soviet Union

Edited with an Introduction by Brian Simon. Translated by J. and M. Ellis, J. McLeish, H. Milne, N. Parsons and others. (International Library of Sociology and Social Reconstruction.) Pp. viii+305. (London: Routledge and Kegan Paul, Ltd., 1957.) 32*s*. net.

This book derives from the work of the Russian physiologist Pavlov, to whom the Western world accords the respect due to a great scientist. It comprises twenty-two papers contributed by contemporary Soviet psychologists and selected as representative by Prof. A. A. Smirnov and N. A. Menchinskaya of Moscow. Their emphasis is upon human rather than upon animal behaviour, and the studies are frequently in terms of the development of the individual.

The field covered by the nineteen Soviet contributors deals with the principal areas of interest to their Western counterparts. Prof. B. G. Ananiev (Leningrad) deals with problems of perception; Prof. L. V. Zankov (Moscow) with memory, and Prof. E. A. Milerian (Kiev) with attention. The paper on psychopathology by Prof. A. R. Luria (Moscow) suggests close research association of Soviet psychologists with neurophysiologists and psychiatrists. Several papers deal with thinking, apparently a subject of considerable interest to the Russian investigators.

It is on the subject of learning that British and American psychologists have derived most from Pavlov's work: the learning process is now given a central place in the subject-matter of modern experimental psychology. The papers in this field deal with the subject somewhat differently and principally in an educational context, rather than in terms of the more usual technique of the Western psychologist, namely, in the context of animal experiments. Thus, for example, Prof. N. A. Menchinskaya (Moscow) sets out to show how the principles governing learning can be applied to improvement of methods of instruction, and reports experiments on the use of visual techniques in training people to think abstractly in mathematics and elsewhere.

Psychology, presented from the point of view of dialectical materialism, exhibits certain characteristics which merit contrast with Western psychology. The Russian work emerges as heavily experimental; the method of psychometric measurement that is also prominent in British psychology is noticeably absent. Again, some of the contributors, notably Prof. B. M. Teplov (Moscow), reject the idea current in Western psychological theory that principles and laws are not "immutable" and "objective" parts of Nature but simply tools for making predictions about natural phenomena. In their theory the Russian contributors exhibit a distinct preference for theoretical concepts of a physiological kind. Contemporary Western theorists, by contrast, are sharply divided as to whether basic units of analysis should be physiological or of some other kind (for example, logical or mathematical).

A paper by Prof. A. A. Smirnov (Moscow) assesses achievements and omissions of Soviet work in the period 1953–55. Here and elsewhere, one notes the wide range of complex psychological processes to which Pavlovian concepts and techniques have been applied: these applications will certainly interest British and American investigators. Despite the explicit rejection of the method of introspection by Prof. Teplov, Prof. Smirnov makes a plea for more study of—among other things—the complex problem of differences of mental imagery. He also makes reference to the need for more study of the history of world psychology, and for more application of the results of completed researches.

A concluding paper gives a Russian assessment of the Fourteenth (Montreal) International Congress of Psychology and indicates that interaction between Western and Soviet psychology is in progress. This book should stimulate more such interaction. The editor, contributors and translators merit our thanks for this valuable and interesting book.

Peter McKellar

MUSCLE PHYSIOLOGY

Die Muskeltätigkeit

Versuch einer Biophysik des Quergestreiften Muskels. Von Prof. Eugen Ernst. Pp. 355. (Budapest: Verlag der Ungarischen Akademie der Wissenschaften, Akadémiai Kiadó, 1958.) n.p.

In the introduction to his book, Prof. Ernst describes the difficulty that he had in deciding to spend a year away from his laboratory in order to write; but there is no doubt that he has done a most admirable and helpful thing, in setting down for us his results and thoughts after forty years work in muscle physiology. It happens all too seldom that a veteran in any field will make the effort to write down, let alone tidy up, the developments in his science throughout his lifetime.

He writes, understandably enough, with an intense sense of personal involvement. He evidently feels that his own contributions have been under-estimated and quotes with some bitterness "The publicity each theory has received has depended almost as much on the strength of personality of its protagonist as on its intrinsic merit".

Prof. Ernst's disputatious style, and his wide reading, combine to give a vivid historical picture of the way in which muscle physiology has developed. In addition, the experimental work for which he is best known—on the volume changes in muscle and on the osmotic activity of water in muscle—is presented in some detail; while numerous other aspects of muscle physiology are reviewed or discussed. Sometimes he does not give enough experimental detail to permit a firm answer to an important question, for example (p. 46), where he reports that isolated myofibrils are excitable electrically; and although some of his criticisms seem to me to be just—for example (p. 266), where he points to the confusion that surrounds the concept of muscular efficiency—he sometimes goes too far, or makes mistakes himself. Thus, in claiming priority over A. V. Hill for the discovery that when an active muscle is stretched it can absorb energy (pp. 11, 321), he seems unaware that his mechanical measurements alone, without heat measurement, cannot possibly solve this problem.

The book is well produced, but there is a cumbersome system of cross-referencing (to chapters and sections instead of to pages) that may have made it easier to write, but which certainly makes it more difficult to read. An infuriating example occurs on the last page (330), where it is implied that Hodgkin and Horowicz have failed to make proper reference to Prof. Ernst's work. To investigate this, a laborious search through the book is necessary, which ultimately arrives back on the self-same page from which it started, where it is found that the vital piece of evidence, by Laszlo, is still unpublished.

Nevertheless, it is Prof. Ernst's sincere interest in comprehending his subject that permeates and dominates his book. The fuel for his polemics seems to be the irritation that he feels because, after so many years work, by so many different people, the field still abounds in uncertainties, contradictions and misinterpretations.

D. R. Wilkie

INORGANIC MICRONUTRIENTS IN PHYSIOLOGY AND AGRICULTURE

Trace Elements

Proceedings of the Conference held at the Ohio Agricultural Experiment Station, Wooster, Ohio, October 14–16, 1957. Edited by C. A. Lamb, O. G. Bentley and J. M. Beattie. Pp. xii+410. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 12 dollars.

The volume under review comprises 23 chapters concerned with quite different aspects of trace-element nutrition, and a summary by Dr. C. A. Elvehjem given at a three-day symposium, which although rather unequal in treatment probably present in some respects more informed accounts than could be achieved by a single author.

Provocative contributions by Arnon dealing with the requirements and roles of trace elements with special reference to vanadium, molybdenum and manganese in different plant organisms, and by Hutner and his collaborators describing a novel approach to methods for revealing nutrient requirements by increasing metabolic stress with some emphasis on cobalt, present what may be termed the philosophy of trace-element investigations.

The chapters on selenium in soils, plants and animals by Moxon, on cobalt requirements by Davis, and on cobalt in B_{12} synthesis by Johnson and Bentley are both timely and informative. Iron is discussed by Granick, zinc by Hoch and Vallee, and copper mainly in relation to uricase by Mahler. Monoiodotyrosine metabolism is described by Serif and Kirkwood, but the use of bare references in place of certain details on methods and previous work are more akin to a paper of a series than a symposium contribution.

The specific role of boron in plant nutrition is still unknown. Skok, however, gives an excellently concise and detailed account of present knowledge regarding boron. Shorter papers by Sayre, and by McLean and Volk, deal with boron in corn and alfalfa.

Nason contributes a comprehensive statement regarding the roles of molybdenum and vanadium in plants and animals. The following paper by Keeler and Varner on molybdenum- and tungsten-protein fractions in *Azotobacter* approaches the problem of whether molybdenum fulfils a single or multiple role in *Azotobacter*.

The chapter by Pirson on manganese in photosynthesis reactions of higher plants and green algæ is a welcome summary regarding the apparent role of manganese in this complex process. Shorter papers discuss manganese problems in soils and in soybeans (Hoff and Medersky), manganese in grape production (Beattie), and manganese toxicity in apple (Winter).

Two chapters by Brown, Eyster and Tanner deal comprehensively with the mineral nutrition of *Chlorella pyrenoidosa* and especially with the differential effects of manganese in heterotrophic and autotrophic growth, respiration and photosynthesis. These papers, with those of Pearson, Arnon, Nason, Hutner and collaborators, Johnson and Bentley, and Keeler and Varner, comprise a fairly comprehensive account of micronutrient metabolism in micro-organisms.

Some minor omissions are of references to both sodium and chlorine in the index in spite of allusions in the text and the indexing of rubidium and fluorine. Reference to work of Brown and Possingham (1957) on iron and cell division is omitted from the text, pp. 378–9 and the index, though it is included in the bibliography, and the main paragraphs on hæmoglobin, pp. 368 and 370, are not indexed. The printing is excellent, and there are probably in all more than 1,000 different references conveniently distributed in relation to each chapter.

This book is recommended as a necessary part of any library used by students and teachers of plant physiology and of mineral nutrition in any field. Research workers will find therein much information on a wide range of trace-element problems and some stimulating or provocative points of view which may encourage further investigations.

E. J. Hewitt

Observation and Interpretation

A Symposium of Philosophers and Physicists. Edited by S. Körner in collaboration with M. H. L. Pryce. (Proceedings of the Ninth Symposium of the Colston Research Society held in the University of Bristol, April 1st–April 4th, 1957.) Pp. xiv+218. (London: Butterworths Scientific Publications; New York: Academic Press Inc., 1957.) 40*s.*; 8 dollars.

THE conference recorded in this volume brought together a remarkably distinguished international gathering of philosophers and physicists. There were seven sessions, at each of which two short papers were presented, and the discussion which followed was tape-recorded.

The main topic is indeterminism in quantum physics, with the problems arising from it. Several of the papers, including those of Profs. Braithwaite, Ayer and Popper, deal with the notion of probability, and discuss whether the frequency view is adequate for use within physics, and how to express the degree to which a belief is supported by evidence. The central argument develops with Profs. Bohm and Rosenfeld as antagonists, and leads to the question whether the laws of quantum mechanics would be the same whether there were human observers or not. Bohm outlines his view that the indeterminacy of quantum physics is not necessarily ultimate but may be explicable by deterministic behaviour at a deeper level, somewhat as random Brownian motions are explained by deterministic motions of molecules. Among the most interesting of the other papers are that of Prof. Körner on regulative principles in physics and that of Mr. Kneale on the question whether we can 'see' atoms.

Most of the papers could be read by anyone interested in the philosophy of science or in quantum physics. The discussions give the reader the excitement of a debate by experts on live and important issues. The volume is a successful experiment in the reporting of an important symposium.

E. F. CALDIN

Science in New Zealand

Edited by F. R. Callaghan. Pp. 272+27 plates. (Wellington, N.Z.: A. H. and A. W. Reed; London: Bailey Bros. and Swinfen, Ltd., 1957.) 22*s.* 6*d.*

AS with the British Association in Great Britain, it has become a tradition for the Australian and New Zealand Association for the Advancement of Science to issue a hand-book on the occasion of its periodical meetings. The holding of the thirty-second meeting in Dunedin in January 1957 was marked by the issue of the present volume. It makes no attempt to be comprehensive in its scope, and its articles aim at dealing with only a selected group of scientific interests. They are written in a style readily understandable by all readers and provide a general background knowledge of the scientific and cultural features of New Zealand.

A distinct local colour and flavour are regarded as an essential feature of an A.N.Z.A.A.S. hand-book and the present volume is descriptive, historical and scientific throughout its chapters.

Among articles of outstanding interest is one by Gilbert Archey on the relationships between Maoris and Polynesians, native and introduced birds by E. C. Turbott, geothermal power by G. W. Grindley, aerial top-dressing by E. A. Gibson, trans-Tasman relationships in natural history by C. A. Fleming, and the growth of hydro-electric schemes by F. R. Callaghan. There is also a valuable introduction showing the contributions made to the development of science in New Zealand by Sir Joseph Banks and Sir Joseph Hooker.

The book is well illustrated, not the least important photograph showing a group of Maori intellectuals considering the new edition of the standard dictionary of their language.

Micro-Organisms in the Soil

By Prof. Alan Burges. (Biological Sciences.) Pp. 188. (London: Hutchinson and Co. (Publishers), Ltd., 1958.) 10*s.* 6*d.* net.

FEW books have been written on soil microbiology since the Second World War, and therefore the present volume, although much biased towards soil mycology, will be most welcome to soil scientists. Workers in general in biological and related sciences should also find something to interest them.

Prof. A. Burges has taken upon himself a heavy task, and he is to be commended for approaching it from the ecological point of view. The opening chapter, which gives a brief account of the soil and its structure, is followed by a chapter on the various groups of organisms found in the soil. No diagrams or photographs are provided and consequently some of the descriptions of the more complicated organisms (for example, nematodes) and the systematics (for example, of the algae) will be fully appreciated only by those trained in zoology and botany. The succeeding chapters deal with such topics as: methods of examining the soil population; form, distribution and ecology of the organisms in the soil; the role of micro-organisms in the biochemical transformations taking place in soil; the influence of man on soil micro-organisms; and a consideration of soil as a dynamic equilibrium system. It is in these chapters that the true worth of the book will be found.

This volume will be very useful to students who have to learn something about soil microbiology and who are looking for an up-to-date account in a comprehensive form. The references at the end will be found of particular value in this connexion.

D. M. WEBLEY

A Treatise on Photo-Elasticity

By Prof. E. G. Coker and Prof. L. N. G. Filon. Second edition revised by H. T. Jessop. Pp. xxxvi+720. (Cambridge: At the University Press, 1957.) 70*s.* net.

THE Cambridge University Press has performed a very real service to all those interested in the theory and history of photoelasticity by producing a second edition of Coker and Filon's classic work on this subject; this was first published in 1931 and has been out of print for many years.

The book has been reprinted by the offset-litho process; it differs from the first edition, apart from a very few minor corrections and alterations, in only two particulars. The colour photographs contained in the original edition have been omitted, presumably to keep down the cost of the new edition, and the reviser, Col. H. T. Jessop, of University College, London, has added an excellent short introduction giving an outline of developments in the field of photoelasticity since 1931 and a short bibliography covering this period.

This new edition is a book which technological and scientific libraries as well as individual workers in photoelasticity will wish to place on their shelves.

E. K. FRANKL

THE NUFFIELD–WITWATERSRAND UNIVERSITY EXPEDITIONS TO KALAHARI BUSHMEN, 1958–59

By Prof. P. V. TOBIAS
Convener, Kalahari Research Committee, University of the Witwatersrand

DURING the winter of 1958 and the summer of 1959, two expeditions from Johannesburg carried out the most comprehensive series of field-studies ever made on the biology of the Kalahari Bushmen. The full collated reports will ultimately form the subject of a special monograph, but a provisional report on the background, organization and achievements of the investigation is presented here.

The Kalahari in Bechuanaland comprises a large area of sand veld, with slight rainfall, scanty vegetation, practically no agriculture, a sparse and often nomadic population and a virtual dependence of man on domestic and wild animals. It includes, too, the swamp-lands and broad rivers of the Okavango inland 'delta', which Prof. J. H. Wellington regards as potentially one of the chief food-producing areas of southern Africa.

The peoples of Bechuanaland fall into the following ethnic categories: (1) Bantu-speaking Negroids; (2) Hottentots; (3) Bushmen; (4) Europeans (Caucasoids); (5) Bastards—a variety of blends of the other four groups.

Of these five categories, the serious decline in numbers of the Bushmen over the past three hundred years, and especially in the last century, has made the study of this group the most urgent. Although recent estimates have placed the number of surviving Bushmen at as high a figure as 50,000 (Tobias, 1956), it has been deemed necessary for a number of reasons to give the highest priority to the Bushmen, in a systematic investigation of the inhabitants of the Kalahari. At present they are being subjected to rapid change in their conditions of life; to progressive blurring of their tribal boundaries in some areas, with consequent cultural and genetic detribalization; and to the impingement of other races, languages and cultures upon their genetic structure, click language and subsistence economy based on hunting and food-gathering.

For more than thirty years the Department of Anatomy of the University of the Witwatersrand has been studying the indigenous population of South Africa in general and the Bushmen in particular, especially the divergences in the skeletal structure of the Bush and Negroid peoples. These skeletal studies have been supplemented by a number of field-surveys over the past twenty years, as a result of which much information has been collected about living Bushmen (see, for example, Dart, 1937). Meanwhile, other studies had been devoted to linguistic, psychological, cultural and medical aspects of the Bushmen, as well as, in more recent years, their applied physiology. For many years, these field-surveys had been carried on in an unsystematic and desultory fashion.

Recent years have seen a considerable revival of interest in the physical anthropology of the Bushman and Hottentot peoples. As a consequence, no fewer than thirty-four papers bearing on this topic were published during the period 1952–55, compared with seven works in this category in the years 1948–51. Studies on the living have included physical and serological accounts of Nama Hottentots, Strandlopers, Koranas, Sandawe, Lake Chrissie Bushmen, Northern Bushmen, River Bushmen, Central Bushmen, and Bushman hybrids.

To co-ordinate and systematize the investigations, as well as to accelerate the work, in the face of rapid changes in the circumstances of the Bushmen, a Kalahari Research Committee has come into being at the University of the Witwatersrand. Its members are drawn from those departments of the University which have been concerned with the Kalahari researches, as well as from two collaborating institutions, the Applied Physiology Laboratory of the Transvaal and Orange Free State Chamber of Mines (director, Dr. C. Wyndham) and the National Institute for Personnel Research (director, Dr. S. Biesheuvel), a specialized institute of the South African Council for Scientific and Industrial Research.

The Kalahari Research Committee has initiated a systematic investigation of the inhabitants of the Kalahari Desert, among whom first place is being given to the Bushmen.

With the aid of a generous grant from the Nuffield Foundation, as well as substantial assistance from the University of the Witwatersrand and a grant from the S.A. Council for Scientific and Industrial Research, the Committee was able to mount the first two expeditions in August–September 1958 and January 1959.

The area selected was Ghanzi, where researches had previously been made on Bushmen (Tobias, 1955–56; Clement, Plotkin and Fosdick, 1956). Around the District Commissioner's camp at Ghanzi, and along a line of European- and Bastard-owned farms running westwards from Ghanzi to the border with South-West Africa, two major linguistic subgroups of the Bushmen meet: to the north and west are the much-studied Northern Bushmen of Dorothy Bleek, whereas to the south and east are the little-known Central Bushmen. The population studied on the 1958 and 1959 expeditions comprised predominantly Central Bushmen, with a smaller proportion of Northern Bushmen. All the branches of study represented on the expeditions were in the broad realm of human biology.

Physical anthropological studies. These were made by Mrs. H. Eriksen, of the Witwatersrand Department of Anatomy, and by Dr. J. S. Weiner, reader in physical anthropology in the University of Oxford. Very few measurements on Central Bushmen have hitherto been published, so the 150 anthropometric and anthroposcopic observations recorded on each of 86 adult males and 54 adult females constitute a valuable addition to knowledge. 81 of these individuals belong to the !ϰ5η (Magon) tribe, which has never previously been studied by physical anthropologists. 20 were of the Naron tribe, of which a small series had previously been published by Tobias (1955–56);

while 21 were Auen (Kaukau) of the Northern Bushmen. The remainder comprised mainly inter-tribal 'hybrids' and Bushman–Negroid hybrids.

For the first time on Bushmen, skinfold measurements were taken with a Harpenden skinfold caliper. The objective assessment of steatopygia and steatomeria was successfully attempted by measurement of skin pinches over the buttocks and thighs. The use of female investigators greatly facilitated this aspect of the work, since Bushwomen are always loth to uncover their buttocks, which are a much-prized feature in their sexual economy. Detailed measurements and observations could likewise be taken on the enlarged labia minora (macronympha or the 'Hottentot apron'). Dermatoglyphic records were taken on palms and finger-tips and will provide a useful basis for comparison with similar observations collected recently on Bantu-speaking Africans from Nyasaland, Tanganyika and the Zambezi Valley in Northern Rhodesia (unpublished results).

The study of skin colour by the old von Luschan tablet has long proved rather inadequate, and an excellent opportunity was provided for a more objective assessment by the use of Dr. Weiner's portable reflectance spectrophotometer introduced in 1951. He collected observations for the skin colour on the inner aspect of the arm and on the fore-arm, from 142 Bushman subjects. These readings will make it possible to specify quantitatively the range of skin colour and to compare this with that of other racial groups on whom the instrument has been used (including West Africans, South African Bantu-speaking Negroids and Australian Aborigines).

Blood-groups, hitherto not assessed on Central Bushmen, were investigated on 114 Ghanzi Bushmen. For the blood-grouping, Dr. A. Zoutendyk, of the South African Institute for Medical Research, has used almost the whole range of anti-sera of anthropological value, including the recently discovered 'negroid' Js and V anti-sera (supplied by Dr. E. Giblett, of Seattle) and the 'mongoloid' Diego (supplied by Dr. T. Layrisse, of Venezuela). The results, which have been published by Weiner and Zoutendyk in *Nature* of March 21, p. 843, confirm the generally negroid pattern of Bushman blood-groups, including the occurrence of V and Js. Diego antigen is totally lacking, while the previously established points of departure of Bushman blood from that of Negroids are confirmed, namely, high frequency of A and low frequency of B and the absence of Rh-(cddee).

Somatotype photographs, hair samples and hand-grip dynamometer readings were also collected by Dr. Weiner, while Mrs. Eriksen made plaster-face-masks of Bushmen to add to the collection of more than six hundred African life-masks built up by Prof. R. A. Dart and his assistants in the Anatomy Department during the past thirty years.

Oral and dental investigation. This was carried out by Dr. J. F. van Reenen, senior lecturer in the School of Dentistry of the University of the Witwatersrand. A clinical and morphological study was made of 278 Bushman dentitions. Nearly half the Bushmen examined had an edge-to-edge bite, generally with attrition. A high incidence of gingivitis and hypoplasia of the enamel was recorded, but the incidence of caries was low. In addition, a bacteriological investigation was made on samples of saliva from 41 Bushmen. First results indicated the presence of hæmolytic streptococci and of coagulase-positive staphylococci in a large proportion of subjects. Few were positive for yeasts and a fair number for lactobacilli.

Applied physiology. During the winter months of 1958, a team from the Applied Physiology Laboratory, University of the Witwatersrand, led by Mrs. J. S. Ward, investigated the physiological responses of Bushmen to cold. It was found that air temperatures ranged from 85° to 93° F. by day down to 29° F. at night. The difference between maximum and minimum temperatures on sunny days and clear nights might be as much as 50–60 deg. F. Relative humidity was low, and no condensation was recorded on any night. The theory has often been canvassed—not without challenge—that the Bushman is peculiarly adapted physically to life in the desert. Apart from the evidence adduced elsewhere (Tobias, 1957) that he is a late arrival on the desert scene, Mrs. Ward's team confirmed earlier observations by Wyndham and Morrison (*Nature*, 178, 869; 1956) that the Bushman's adaptation to Kalahari conditions is largely cultural, rather than anatomical or physiological. By the intelligent use of fire, shelter and individual bodily covering, the Bushmen create comfortable temperature conditions during the cold winter nights. Physiological indications are that Bushmen, like Europeans under these air conditions, suffer a fall in skin temperature and increase their metabolism by shivering.

In January 1958, a second team from the Applied Physiology Laboratory, under Dr. N. B. Strydom, studied heat responses of Bushman males to humid heat in a specially devised climatic tent. Pulse-rate, rectal temperature and loss of weight were recorded hourly during a 4-hr. stop-test in a saturated environment of 90° F.

The variable electro-cardiographic response of Africans on cooling of the precordium led Dr. B. Kaminer, senior lecturer in physiology, University of the Witwatersrand, to study with a portable cardiograph the records of 60 male Bushmen and to make precordial cooling experiments on 14 Bushmen. Arterial blood pressure readings on 102 Bushmen revealed no tendency for pressure to increase with age. In addition, water 'load' tests were made on 10 Bushmen and clinical examinations on 78 Bushmen.

Psychological performance testing. This was carried out by Dr. H. Renning, of the National Institute for Personnel Research, Johannesburg. His first problem, to determine whether the Bushmen are amenable to simple performance testing, could clearly be answered in the affirmative, and 86 males and 15 females were tested. The tests used were: (1) sand drawing; (2) pattern completion (coloured version); (3) object-relations test (Zilian); (4) Ishihara colour-blindness; (5) Müller–Lyer illusion (method of limits); (6) perceptual illusions (Herskovits *et al.*); (7) recognition of shape. Of these, only the Müller–Lyer illusion presented difficulties to the subject. All other tests, none of which required any verbal responses, appeared to give reliable results. Some tests requiring the handling of paper (for example, the 7-squares test) could not be used in the open, because of prevailing strong winds; and, in general, test sessions could not be extended beyond 40–50 min. without imposing an undue strain on the subject.

Although the evaluation of results will not be completed for some time, a few points can be made immediately:

(i) The intellectual capacity of the Bushmen tested varied over a wide range.

(ii) Personality and temperamental differences were also great and readily observable in responses to test situations. Emotional tension was marked in many subjects during the first 10–15 min. of the test session.

(iii) The ability to abstract is apparently little developed in the Bushmen. For example, whereas a simple alternation, in the object-relations test, of black/white/black/white, or square/round/square/round, was in most cases correctly continued when two pairs were presented, the series of black square/white square/black round/white round was found too difficult even when three complete cycles were laid out by the experimenter.

Dr. A. J. Clement, who led the expedition into the field and established its bases, collected further demographic data on the numbers and distribution of eight western Kalahari tribes. These data largely confirmed those collected earlier by Tobias (1956).

Nearly thirty years ago, Schapera (1930) wrote: "There seems little doubt that the Bushmen are steadily dying out as a race. What relentless persecution at the hands of other peoples has not achieved is being slowly accomplished by disease and racial intermixture. Racially pure Bushmen are already in a minority, and their ultimate absorption by their neighbours is probably inevitable".

Since then, though the factor of disease may have declined somewhat, intermarriage of the Bushmen with other peoples has continued apace under more settled conditions, so that both tribal and racial boundaries are rapidly becoming blurred. There is a distinct danger that the extinction of the Bushmen by hybridization is foreseeable and that, thereby, anthropologists will be robbed of the chance of gaining a most important insight into human development and adaptation. It is hoped that such a tragic default will be averted by the concerted survey launched by the Kalahari Research Committee.

THE MEDICAL RESEARCH REACTOR AT THE BROOKHAVEN MEDICAL RESEARCH CENTER

By Dr. E. E. STICKLEY
Medical Department, Brookhaven National Laboratory, Upton, Long Island, New York

After nearly five years of planning and more than two years in construction, the new Medical Research Center at Brookhaven is nearing full utilization as its unique Medical Research Reactor—the first in the world—has reached critical reactivity. This event occurred on March 15 at 9.44 p.m. New York time. The critical mass was established as 2·249 kgm. of uranium-235. Operation in the full power-range was achieved on April 3.

Since the design of the reactor was fully studied during the planning and testing stage, it is expected that the machine will come quickly into experimental use, bringing the new establishment nearly to a completely functioning state. The Medical Research Center buildings were dedicated on December 16 last, and the Research Hospital was transported from the old quarters as a unit and set up completely in its new space on January 6, while moving of the laboratories was completed in mid-February.

It is significant that this reactor is the first where every salient aspect of the engineering and design of the device was considered in relation to its use in the study of man and the diseases of man. Its conception and planning were an outgrowth of the pioneering investigations using the unequalled possibilities afforded by the large general-purpose reactor at Brookhaven, where the first experiments on neutron-capture therapy and medical applications of radioactivities of extremely short half-life were carried out. Eight years of experience with this reactor, gained through the extraordinary research flexibility of that device and the unstinted aid of its scientific, engineering and operating personnel, have prepared the way for further penetration into this unexplored region of medical-nuclear research with this newest tool.

Since the Medical Research Reactor was designed specifically for use in the research programme of the medical scientists on the Brookhaven staff, the initial decisions established the quality and quantity of neutrons required to advance the technology of the earlier medical experiments. The major requirements were an increase in the slow-neutron flux, better control over the energy of the neutrons, and improved clinical convenience. From a statement of the neutron requirements, a reactor core and reflector were specified, and around them appropriate special shielding was planned to permit the utilization of the greatest possible external neutron flux. Two shielded rooms have been built, one on either side of the reactor, separated from it only by a single wall. Vertically moving shutters of 20 tons weight have been installed to control the administration of the radiation. A smaller cell has been incorporated inside the shielding for studies of the whole-body effects of nuclear reactor radiations. Other experimental arrangements include tubes into the reactor structure for production of short-lived radioactive materials, as for use in therapeutic and diagnostic studies or activation analysis; the tubes are also adaptable for collimated neutron beams, which are of value in determining the penetration and energy changes of neutrons passing through tissue-equivalent materials.

The operational criteria were best met by a modified tank-type reactor in which the neutron moderation is supplied partly by graphite in sealed cans and partly by the natural water circulated for cooling. The core is further surrounded by a reflector of air-cooled graphite approximately 1 m. thick. Initially there are 17 fuel elements, made in the Bulk Shielding Reactor design, each fabricated from 18 thin laminated plates spaced to allow passage of cooling water. A total loading of 2·377 kgm. of highly enriched uranium-235 is used. Three safety rods, each worth 2 per cent of excess reactivity, are held by magnetic clutches;

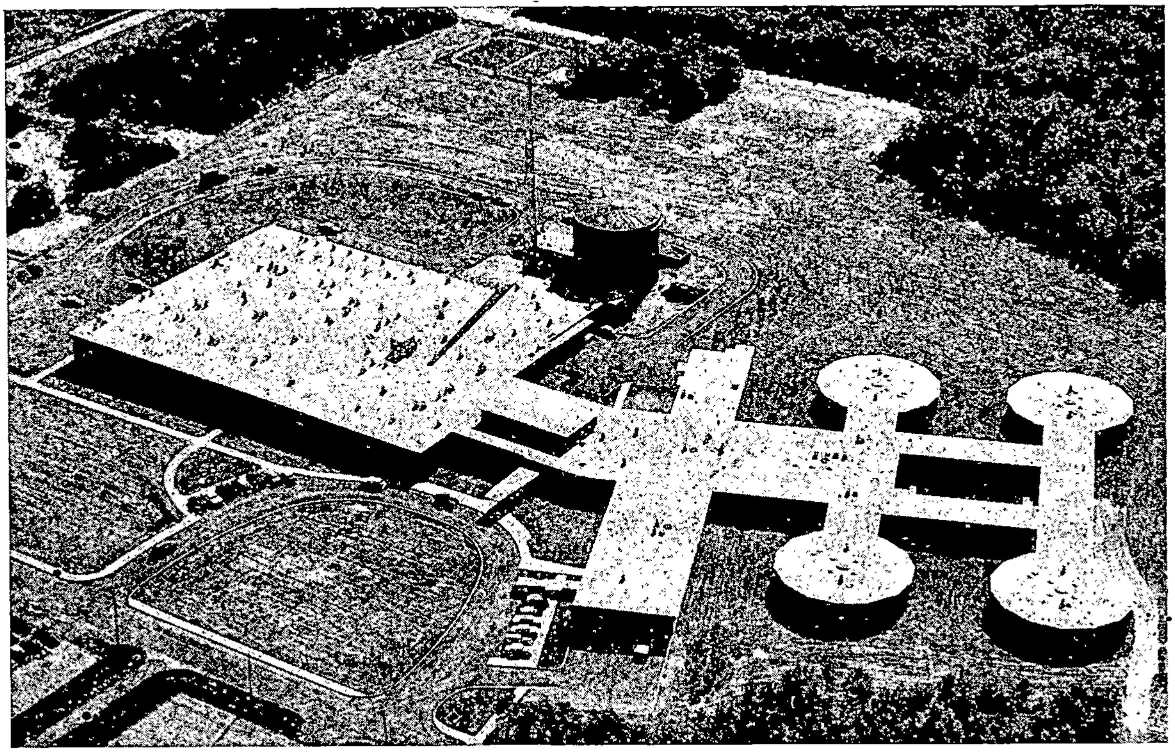

Fig. 1. Aerial view of the Medical Research Center. The reactor building appears above the centre of the picture. Research Hospital at the right. Industrial Medicine Clinic wing, lower centre. Medical Research Laboratories are at the left

they are driven into the core by gravity. Each consists of a stainless steel sheath with cadmium lining and boron carbide filling. A single control rod of similar pattern in solid steel, worth only 0·5 per cent in reactivity, is used for routine operation. At the nominal full power of 1 MW., the Medical Research Reactor is expected to have a core flux of 10^{13} and should deliver 7×10^{10} neutrons/cm.^{2}/sec. into the treatment room; this is twenty times the best flux previously available. Provision has been made for development of combinations of moderators, reflectors, filters and converter plates to select and modify the variety of radiations available in its several exposure sites.

Of these many uses and features of the Medical Research Reactor, three of outstanding immediate interest are: (1) the therapeutic application of high concentrations of slow neutrons delivered through the reactor shielding into a treatment room for the production of instantaneous radiation reactions, especially of the energetic heavy-particle variety; (2) the production of radioactive materials of very short half-life, to investigate their therapeutic and diagnostic possibilities; and (3) the development of more powerful analytical or diagnostic tests by the methods of neutron-activation analysis. In addition, other important applications lie in the use of the full range of reactor-produced radiations for studies of their comparative effectiveness in a wide variety of living systems and other materials of biological interest.

The Reactor is directly connected with the laboratories and the hospital through an air-lock corridor. To facilitate its use in the varied types of investigation for which it is expressly suited, a fully equipped operating room is adjacent, and treatment rooms for the application of high-level radioactive procedures are immediately at hand. The arrangements have been planned to eliminate any inconvenience in preparation or treatment of patients in carrying out the experimental procedures.

The Research Hospital provides a total of 48 beds in four circular pavilions, so arranged for the best control and convenience in observation and care; all the necessary additional service functions of a self-sustaining hospital are included. An Industrial Medicine Clinic occupies an adjoining wing, providing out-patient care and serving the occupational health needs of the Brookhaven National Laboratory as a working community. The Hospital and Clinic for handling patients are balanced by five related research divisions within the Department under the basic science headings of Physiology, Biochemistry, Microbiology, Experimental Pathology and Medical Physics. The nominal size of the scientific staff of the Medical Department is 48, all holding doctorates, two-thirds of them in medicine.

Research in clinical medicine and in fundamental laboratory medicine utilizes radiation both as a causative agent and as a label for constituents of living systems. Typical of this field is the intensive study of the relationships of radiation to blood dyscrasias. Radiation is used to induce disease for experimental study on one hand, while on the other, materials tagged with radioactivity are used to elucidate the natural history of the elements of the blood in comparison with their history under conditions of disease. It is of especial interest to note that efforts of the biochemists and the hæmatologists at Brookhaven to produce a radioactive substance which could deliver radiation selectively to the interior of cells did not bear directly the intended result, but

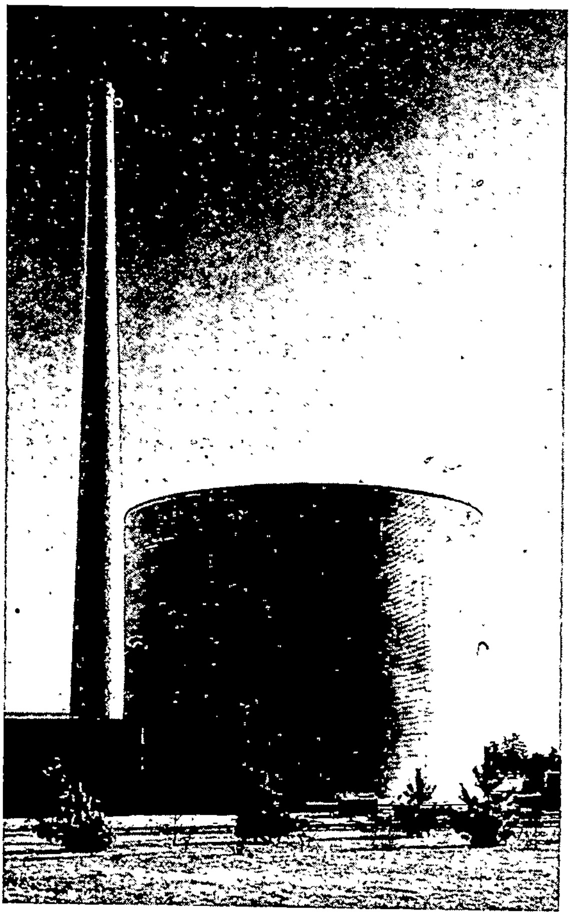

Fig. 2. Medical Research Reactor building. Cooling air for the reactor's graphite reflector is forced out of the 150-ft. stack. The steel reactor building, which is 60 ft. in diameter and 54 ft. high, is connected to the main medical research complex, where the hospital and laboratories are located

did unexpectedly provide one of the most valuable of biological tracers—tritiated thymidine—a tagged compound which immediately enters the cycle of blood constituents, appearing rapidly in large mononuclear cells of the peripheral circulation. Similarly, an attempt to develop a therapeutic application of a rapidly decaying radioisotope of manganese became an avenue opening up a broad investigation into the presence and the behaviour of trace metals in health and disease.

Much of the research programme and future planning are directed toward the special medical problems to be met in the coming nuclear age; novel tools are coming into use and are being used in various ways. Among Brookhaven's 'big machines', noteworthy use has already been made of the reactor; the high biological significance of neutrons of intermediate energy are being evaluated with a small cyclotron and a Van de Graaff accelerator; the large cyclotron has provided deuteron beams as well as rare radioactive isotopes from heavy-particle bombardment; the Hot Laboratory has searched for desirable radioactive materials of special metabolic properties. The collaboration of the scientific and technical staff at Brookhaven illustrates the co-operation which has stimulated and assisted the work of the Medical Department in its first ten years, as it grew into the present research establishment with its unique capabilities. The Medical Research Center is thus an integral unit in a scientific community of some four hundred scientists and engineers working on all the problems of the utilization of nuclear energy.

Brookhaven National Laboratory is a civilian establishment operated under the guidance of nine major universities of the eastern seaboard of the United States; they supervise its administration through Associated Universities, Incorporated, which makes contracts with the U.S. Atomic Energy Commission for supporting funds. The Laboratory is in the centre of Long Island, 70 miles east of the middle of New York City on a campus converted from the Army's former Camp Upton. In the years from its inception in 1947, as a result of the foresight of leading scientists in the new fields which research with the big machines opened up, Brookhaven has become familiar ground to hundreds of visiting and collaborating scientists from many foreign lands, all of whom have been welcomed for their contribution to the 'peaceful uses of the atom'.

The work described here is supported by the United States Atomic Energy Commission.

OBITUARIES

Prof. Arturo Duperier

Prof. Arturo Duperier, who recently died in Madrid at the age of sixty-two, was distinguished by his pioneer researches into the variation of cosmic-ray intensity with time and with meteorological conditions. He began this work in 1938 when he came to work with me and my cosmic-ray colleagues in the Physical Laboratories of the University of Manchester. Soon after the outbreak of the Second World War, when the cosmic-ray group largely dispersed for war activities, he moved his apparatus to the Imperial College of Science and Technology, London, where Prof. George Thomson gave him laboratory space. In a small room near the top of the Royal College of Science building at South Kensington, Duperier set up a cosmic-ray recording set and ran it almost continuously throughout the War and bombing, and for some years afterwards.

It was the results obtained from this long period of very precise recording of the cosmic-ray intensity which provided Duperier with the material for his analysis. His most important technical achievement was the introduction and use of multiple correlation methods for disentangling the origin of the observed variations of cosmic-ray intensity. In this way he was able to show quantitatively how the observed dependence of the cosmic-ray intensity on temperature might be an effect due to the decay of muons in the atmosphere. By careful use of meteorological data obtained from radio-sonde observations, Duperier was able to locate the average height of production of the muons as about 16 km. His method was to assume that the intensity varied both with the atmospheric pressure and with the unknown height of the muon-producing layer, and then to determine that value for the height of the layer for muon formation which gave the largest partial correlation coefficient.

This work demanded the meticulous analysis of a great amount of numerical data, at which Duperier was exceedingly expert. To facilitate this work he pioneered the use of business accounting machines for the analysis of cosmic-ray data. Later he refined his analytical method by introducing a three-term regression formula, and by this means obtained some indication—but no final proof—of the effect on the cosmic-ray intensity at sea-level of the pion decay in the upper atmosphere. This last work was carried out at Birkbeck College, where he moved soon after the War. In 1945 he gave the Guthrie Lecture to the Physical Society of London on the "Time Variations of Cosmic Rays".

Duperier was well known to cosmic-ray workers all over the world and regularly attended the biennial meetings of the International Cosmic Ray Conference, under the auspices of the International Union of Pure and Applied Physics, which has met since the War in Poland, India, France, Mexico and Italy. He will be greatly missed at the next meeting, planned for this summer in Moscow.

In 1951 Duperier returned to Spain, where he resumed his professorship in the Faculty of Science in the University of Madrid. The loss to his country of the most distinguished Spanish atomic physicist of his generation is indeed great. He was awarded posthumously the Juan March Foundation prize of 500,000 pesetas for his outstanding scientific work.

Throughout Duperier's thirteen years in England, I was in close touch with his work, and came greatly to admire him not only as a scientist but also as a man of unbending rectitude of character. It is thus both as a fine scientist and as a close personal friend that I mourn his death. P. M. S. BLACKETT

Prof. Pierre Fauvel

PIERRE FAUVEL, professor in the University of Angers, who died on December 12, was one of the greatest systematic zoologists. A specialist on Polychaeta, a group with which his name will for ever be associated, Fauvel was supreme in his field. No one who preceded him and none of his contemporaries approached the brilliance of his systematic interpretation.

Fauvel was born at Cherbourg on October 8, 1866. Throughout the greater part of his professional life he was on the staff at the Catholic University of Angers, as professor of zoology for fifty-three years, with a term of office as dean of the Faculty of Science from 1942 until 1947.

In the early stages of his career, 1894–1909, Fauvel worked on human physiology, publishing papers on digestion and uric acid secretion, and on general marine biology. In the latter field he carried out research on the larval development of *Arenicola*, on the circulation in Amphictenidae, on otocysts and on nephridia. For his doctorate of science he published observations made on the Ampharetidae. During 1910–20, however, the trend towards systematics becomes more apparent, and Fauvel's first major work in this field was on collections of polychaetes made in the Mediterranean and Atlantic during cruises of *l'Hirondelle* and *Princesse Alice*, under the direction of Prince Albert of Monaco. There followed papers on collections from the Falkland Islands, Australia, West Africa and Madagascar in this period, and all indicated that a new and brilliant figure had arisen.

With the publication in 1923 and 1927 of his two volumes in the "Faune de France" series, Fauvel's position as the outstanding authority on polychaetes was established. He provided in these works a practical method of identifying almost 900 species, his sedulous preparation of keys, in particular, being of the greatest value. In the genera *Harmothoë*, *Nereis* and *Serpula*, numerous species, previously a jumbled assortment of specimens and populations, were reduced to a series of well-defined natural groups as clearly delineated as available knowledge allowed. For those most difficult of families, the Phyllodocidae and Syllidae, his consideration of the species concept brought order out of confusion. This same ability to define species and clarify taxonomic problems is evident in all the families, so that these volumes have been in continual use in practical marine courses throughout the world since publication, and will probably not be replaced, even by local faunal publications, for years to come. Marine ecologists and physiologists everywhere praise their value and no specialist would consider approaching a problem concerning polychaetes before first noting what Fauvel had to say. In addition, these two works represent models of how the perfect faunal study should be presented, and their extension to other groups (and other areas for Polychaeta) is of paramount importance.

In 1932 Fauvel's work on the polychaetes from the Indian Museum in Calcutta was published, and this also is an invaluable guide to the student and specialist. It was the first comprehensive publication on polychaetes from subtropical and tropical waters, and has been the basis of all later diagnoses of the Indo-Pacific fauna.

Through experience with populations from widely separated regions, Fauvel was able to demonstrate the cosmopolitan nature of many species and the unique endemic elements in particular areas. He was the first to recognize the occurrence in Europe of *Mercierella enigmatica* as an invasion, possibly from India, of a species capable of breeding in waters of low salinity. Since then, repeated records of this polychaete from harbours in western Europe have indicated how damaging the effects of its growth might be.

Honours, richly deserved, were paid to Fauvel by his native France; they included: Chevalier de la Légion d'honneur; Lauréat de l'Institut, Prix Savigny de l'Académie des Sciences; Membre de la Société Zoologique de France; Membre Correspondant du Muséum d'Histoire naturelle de Paris. It is indeed with pride that systematic zoologists can point to the career of Pierre Fauvel, for he always upheld the finest traditions of learning in pursuing his chosen subject to the utmost of his ability, and he gave to zoology some of the finest products of scholarship published during his life-time.

NORMAN TEBBLE

Dr. Herbert Hunter

DR. HERBERT HUNTER died on February 21 at Meldreth, near Cambridge, at the age of seventy-six, after a long and productive working life, during which he had made outstanding contributions to plant breeding, to agriculture and to the malting and brewing industries. He will always be remembered for his activities in these fields, and also as a dedicated research worker and student of his subject who kept his interest in his work up to the time of his death.

Hunter graduated from the University of Leeds, of which he was a D.Sc., and started his researches into barley breeding in the early 1900's. This early work was conducted in Ireland, where he was head of the Plant Breeding Division, Department of Agriculture, Dublin, while he also became the first director of the Stormont Plant Breeding Station in Northern Ireland. Later, during 1936–46, Hunter was director of the Cambridge University Plant Breeding Institute. When in Ireland he bred the hybrid barley variety, Spratt-Archer, which was afterwards to make his name when it became one of the most successful varieties of cereals ever bred for Great Britain. It was introduced into cultivation in 1914, and has only been superseded as a standard malting barley in recent years. Hunter went to Cambridge in 1924, and he there bred two more varieties of barley—Earl and Camton—and a winter oat variety named Picton. All these varieties found a place in British agriculture and received official recommendation for farmers. Hunter's contributions gave him an established position with Sir Rowland Biffen and Dr. E. S. Beaven as successful pioneer plant breeders exploiting the new genetic knowledge.

This work ensured the recognition of Hunter's name nationally and internationally, but he also acquired a great reputation as a writer. He started contributing scientific papers and articles as early as 1908, and maintained a steady output throughout his life. He was an easy, lucid and fluent writer, and found an outlet for his talent in writing books, of which he had a number of successes to his credit. He wrote a standard work on oats, and one on barley in the 1920's, while in 1931 he edited a new edition of Baillière's "Encyclopædia of Agriculture" (with H. Martin Leake), while his most recent contributions were "Crop Varieties" (1954) and "The Barley Crop" (1956).

One of Hunter's great interests was the work of the National Institute of Agricultural Botany, to which he gave most valued service as a member of Council for twenty-one years, as acting director during the Second World War, and as chairman of Council for three years. For his services he was elected a vice-president of Council, a signal recognition of the way in which he guided the Institute's work and activities and established its present important relationships with agriculturists and commercial interests in the seed trade. Hunter's great tact, wisdom and kindliness were all instrumental in accomplishing this work so successfully, and those who worked under him in both Institutes which he directed were grateful for the experience.

In 1911 Herbert Hunter married Rosa Wise, of Springfield, Ohio. She died in 1945, and Hunter married in 1951 Mrs. Blanche Metters, widow of J. D. Metters. He is survived by his widow and two daughters of his first marriage. G. D. H. Bell

Dr. Alexander M. Cockburn

On February 28 Dr. Alexander Murray Cockburn, senior lecturer in geology in the University of Edinburgh, died at the age of fifty-seven.

Dr. Cockburn graduated with first-class honours in geology at Edinburgh in 1924. After a season with the Geological Survey of Canada, and some time spent in studying volcanic phenomena in Hawaii, he returned to his native city to take up postgraduate research as a Falconer Fellow of the University. In 1927, with John Mathieson, Dr. Cockburn carried out the first detailed topographic survey of the St. Kilda group of islands, and in the following year he completed a geological study of these islands, which was published in the *Transactions of the Royal Society of Edinburgh* in 1935, and remains a distinguished contribution to our knowledge of Scottish geology.

Dr. Cockburn was awarded the degree of Ph.D. in 1929, and was elected a Fellow of the Royal Society of Edinburgh in 1935. He began his long service as a member of the staff of the University of Edinburgh in 1931, and passed successively through the positions of assistant and curator of the museum, lecturer, and senior lecturer. In 1942, he took over from Prof. T. J. Jehu the courses in stratigraphy, and since then he was responsible for the formal stratigraphy courses in the Department. However, he never lost his early interest in vulcanology, and he made a comprehensive study of the volcanic rocks of the Pentland Hills. It is most unfortunate that his early death should have prevented him from publishing more than a small part of this work.

From 1951 onwards Dr. Cockburn acted as director of studies in pure science, and he was a member of the Senatus Academicus of the University of Edinburgh from 1956. A prominent Fellow of the Edinburgh Geological Society, he served as honorary secretary during 1939–44, and was elected president in 1958.

These few details of Dr. Cockburn's career can reveal little of the enormous debt which is owed to him by his Department and by all who have been associated with it. He combined a complete and unselfish loyalty to his subject and his Department with a deep and stimulating understanding of the personal problems of his students. He was a most able and conscientious teacher, both in the lecture room and in the field, and he carried a considerable administrative load. One of his great interests was the geological museum, and to this, and to the care of the Grant Institute building, he devoted a great deal of time and skill. Recently he has played a large part in the planning associated with a new building programme, and in the change from a three-year to a four-year honours course in geology. All the students who came under his care will remember with gratitude and affection the help and advice which he gave so readily, and his unfailing kindness, wisdom and good humour. All who were fortunate enough to know him feel a tragic sense of personal loss. F. H. Stewart

Dr. S. Bekku

By the death on September 19 last in Tokyo of Dr. S. Bekku, Japan has lost one of her distinguished electrical engineers.

Dr. Bekku was born at Ueno, Tokyo, in 1893, and he graduated in electrical engineering from the Tokyo Imperial University in 1917. After graduation he pursued advanced studies in the Electro-Technical Laboratory on electrical power transmission and high-voltage engineering. It was at this stage that Dr. Bekku had the opportunity of going to the United States and working with the Westinghouse Electric Company under the direction of Dr. C. L. Fortescue. In 1927, Dr. Bekku received the degree of doctor of engineering from the Tokyo Imperial University, and in 1928 he was appointed to a professorship in the Tokyo Institute of Technology. Here he lectured on transmission and high-voltage engineering. In 1931, Dr. Bekku took up an appointment with the Sumitomo Electrical Industries, where he was responsible for important research and development work in the field of electrical power transmission and distribution.

During the period up to the outbreak of the Second World War, Dr. Bekku published papers dealing with measurements on overhead transmission lines, unbalanced alternating current circuits, concentric cables and power capacitors.

In 1952, Dr. Bekku was elected president of the Institution of Electrical Engineers of Japan. In 1956, the Central Power Research Laboratory, a research association which serves the nine major electricity supply organizations in Japan, appointed Dr. Bekku its director and he was responsible for work on the development of the 380-kV. transmission system.

Dr. Bekku took great pleasure in the maintenance of his contacts with electrical engineers and physicists in the United States. He had travelled extensively in Europe and America and he enjoyed climbing and skiing. Dr. Bekku is survived by his widow, two sons and two daughters.

NEWS and VIEWS

The Rockefeller Foundation : New Officers

DR. J. GEORGE HARRAR has been elected vice-president of the Rockefeller Foundation. Dr. Robert S. Morison has been elected director for medical and natural sciences, a programme merging the biological, medical and public health interests of the Foundation. Dr. John C. Bugher is to be consultant on nuclear energy and as a principal officer will assist all programmes with respect to the impact of nuclear energy. Dr. Albert H. Moseman has been appointed deputy director for agricultural sciences, the new designation of the former agricultural programme. Dr. Lindsley F. Kimball continues as executive vice-president and Dr. Warren Weaver as vice-president for the natural and medical sciences.

Dr. Harrar joined the Foundation in 1943 as local director for the agricultural operating programme in Mexico. He became deputy director for agriculture in 1952 and director in 1955. Dr. Harrar is also serving in a special capacity as director of the National Academy of Sciences Survey on Education, Science and Technology in Africa south of the Sahara. When he joined the Foundation he was the sole staff of its agriculture programme. Established with Dr. Harrar's arrival in Mexico in 1943, this agricultural programme now has operating units in Mexico, Colombia, Chile and India, an extensive international fellowship and scholarship plan, and a grants programme in support of agricultural research and education. Approximately 6,270,000 dollars was appropriated last year by the Foundation in support of these three types of activities.

Dr. Morison was formerly director for biological and medical research in the Foundation. A graduate of Harvard University and of the Harvard Medical School, he taught in the latter before joining the Foundation in 1944. Dr. Bugher, a member of the Foundation's staff since 1943, was given leave of absence to serve for four years as director of the Division of Biology and Medicine of the U.S. Atomic Energy Commission. He returned to the Foundation in 1955 as director for medical education and public health. He represented the Atomic Energy Commission officially at the Geneva Conference on the Peaceful Uses of Atomic Energy in 1958 and is a member of the Commission's advisory committee on biology and medicine. Dr. Moseman joined the Foundation in 1956. He was previously director of crops research of the agricultural research service of the U.S. Department of Agriculture.

National Science Foundation Office of Social Sciences

THE National Science Foundation has recently established an Office of Social Sciences with Dr. Henry W. Riecken as its head. The Foundation has also appointed an Advisory Committee for the Social Sciences to advise on programmes and policy, the members of which are: Dr. Leonard S. Cottrell, social psychologist, Russell Sage Foundation ; Prof. Fred Eggan, professor of anthropology, University of Chicago ; Dr. John Gardner, president, Carnegie Corporation ; Dr. Pendleton Herring, president, Social Science Research Council ; Prof. Joseph Spengler, professor of economics, Duke University ; Prof. S. S. Wilks, professor of mathematics, Princeton University ; and Dr. Dael Wolfle, executive secretary, American Association for the Advancement of Science. The National Science Foundation intends to support basic research in the social sciences, since such support is invaluable in assisting social scientists to improve their research techniques, to accumulate fundamental knowledge about human behaviour and society, and to develop sound theoretical bases for further inquiry.

British Scientific Attaché in Moscow : Mr. D. A. Senior

MR. D. A. SENIOR, of the Royal Naval Scientific Service, has been appointed to the newly created post of scientific attaché to the British Embassy in Moscow ; he will advise the British Ambassador, Sir Patrick Reilly, on scientific matters and report on Soviet scientific and technical development in the civil field. Mr. Senior, who is thirty-five, will hold the rank of senior principal scientific officer and will be on the staff of the Department of Scientific and Industrial Research. Mr. Senior attended Batley Grammar School, Yorks, where he won an open scholarship to Trinity College, Cambridge. He graduated at Cambridge in 1943 with first-class honours in mechanical sciences (with distinction in electronics). He also won the Charles Lamb Prize in electrical engineering. In 1946 he shared the John Wimbolt Prize in civil engineering. From Cambridge he entered the Naval Construction Research Establishment at Rosyth, where he worked on high-speed photography. Since 1950 Mr. Senior has been at the Admiralty Research Laboratory, Teddington, mainly investigating problems of instrumentation and combustion. Recently, he carried out a study of acoustic methods of fish-finding. He has also been studying combustion on a part-time basis in the Chemical Engineering Department of the Imperial College of Science and Technology, London. Mr. Senior has a good knowledge of French, German and Russian. He is married and has three sons.

Peabody Museum, Yale: Prof. C. O. Dunbar

Prof. Carl O. Dunbar, who will retire from the directorship of the Peabody Museum at Yale on July 1, will then have served thirty-nine years on the faculty of Yale and sixteen years as director of the Museum. Prof. Dunbar graduated at Kansas in 1914 and obtained his Ph.D. at Yale in 1917. He was appointed assistant professor of historical geology at Yale in 1920 and then held various other geological appointments at the same University until he became curator of invertebrate palæontology and eventually director of the Peabody Museum. Dunbar is a palæontologist of international reputation and the author of many papers, and he has been editor of several scientific journals. His chief work concerned brachiopods and the Permian foraminifera. He is a Fellow of the Geological Society of London. His distinguished directorship of the Peabody Museum has been characterized by a wise and progressive policy.

Dr. S. Dillon Ripley

Dr. S. Dillon Ripley, a member of the faculty of Yale since 1946, has been appointed director of the Peabody Museum in succession to Prof. Dunbar. Prof. Ripley is an outstanding authority on birds, particularly those of the Far East, and is president of the International Council for Bird Preservation, an organization with sections in forty-five countries. Ripley graduated at Yale in 1936 and took his Ph.D. in zoology at Harvard in 1940. He served in the Second World War with the Office of Strategic Services, and was appointed to Yale as lecturer and assistant curator of zoology in 1946 and became associate professor in 1955. He has spent the major portion of the time outside the United States in the study of bird life. In several Asiatic areas he has been the first white man seen by the local population. He is also a distinguished writer and his works combine philosophy and literary quality with the recording of scientific facts. With such a background of experience the future of the Peabody Museum and its collections is assured.

The Argus High-altitude Geophysical Experiments

Dr. Alan T. Waterman, director of the National Science Foundation, and Dr. Detlev W. Bronk, president of the U.S. National Academy of Sciences, have issued a joint statement referring to the Argus high-altitude geophysical experiments last August and September. Reduction, analysis and evaluation of the observations have been going on, in order to interpret those of scientific significance. Plans are well advanced for the orderly distribution to the world's scientists of appropriate scientific information, as a part of America's participation in the International Geophysical Year. As scientific papers are completed, publication will proceed through the appropriate scientific journals. In addition, plans have been made to summarize the scientific results in the course of one of the four symposia to be held at the annual meeting of the U.S. National Academy of Sciences during April 27–29.

Atomic Power Station for Japan

The Japan Atomic Power Company has announced in Tokyo that on April 3 it had issued a letter of intent to the General Electric Co., Ltd., of England, for the construction of a 150-MW. atomic power station at Tokai-Mura, some seventy miles north-east of Tokyo. This order will be worth in the region of £20,000,000 and marks an important step forward for the General Electric Company, which has been reorganized into three main groups with the view of giving greater drive to its main activities, particularly the development of its heavy engineering and nuclear energy side. The success achieved in Tokyo has been accompanied by several other large engineering orders during the past month, including an order for two 200-MW. turbo-generator sets for the Kincardine station of the South of Scotland Electricity Board, valued at about £4,000,000, and an order for a complete ore preparation plant for the Redbourn Works of Richard Thomas and Baldwin, Ltd., valued at about £1,250,000.

Popularizing Astronomy

The International Geophysical Year and the launching of artificial satellites have led to a greater public awareness of scientific developments. This has created a need for the supply of accurate information in a more systematic manner than is possible in the average newspaper and with less technical detail than is appropriate even in an avowedly popular scientific magazine. The series of twelve articles which Dr. R. A. Lyttleton is contributing to the *Illustrated London News* is therefore especially welcome. Under the general heading, "The Universe at the Beginning of the 'Space Age' ", Dr. Lyttleton has written twelve articles. The first of these appeared on February 21, and the others are being published weekly in subsequent issues. The facilities provided by the *Illustrated London News* through their artist, Mr. G. H. Davis, are being used to great advantage in illustrating the articles. The first two articles dealt with the Earth and terrestrial meteorite craters. The next six deal with the Sun, planets, comets and the origin of the solar system, and the last four articles will deal with the universe of stars and galaxies.

Navigational Aids

In reply to questions in the House of Commons on March 18, asking for a statement regarding the recent meeting of the International Civil Aviation Organization at Montreal, the Minister of Transport and Civil Aviation, Mr. H. Watkinson, said that, in the Government's view, present standards of safety in congested air space could not be maintained with the use of VOR-DMET, the United States system of short-range navigational aid for aircraft, without seriously reducing the efficiency of air traffic control. Although twenty of the thirty-seven countries represented at the Conference voted for the adoption of this system, the British Decca system was the only navigational aid at present available which met the requirements of the International Federation of Air Line Pilots Association for an accurate and reliable short-range navigational aid based on the area coverage system, and designed to provide pictorial presentation of navigational information to the pilot in the cockpit. In the Government's view the Conference had not based its considerations on sound and objective grounds and the Government would continue to press for a more satisfactory solution. Mr. Watkinson hoped that the final decision, which vitally affected air safety, would be taken on proper technical grounds and not on grounds subject to pressure, national prestige or any other consideration than that of the safety of passengers in the air. Mr. Watkinson deprecated the lobbying that had occurred and agreed that, as neither system was fully proved, it would be wise to leave the decision for a period for further technical experience to be accumulated.

Research Associations

In answering questions regarding the British Hat and Allied Feltmakers Research Association in the House of Commons on March 17, the Parliamentary Secretary to the Ministry of Works, Mr. H. Nicholls, said that the Department of Scientific and Industrial Research had recently rejected the idea of a special grant to the Association in view of its development of No. 11 antishock felt in the production of protective caps for motorists and other road users. The Road Research Laboratory had been consulted by a hat manufacturer and had suggested that felt might be used in protective hats, and the manufacturer and the Research Association had co-operated with the Laboratory in selecting a quality, density and thickness of felt for antishock protection; but he stressed that such felt hats were no substitute for the motor cyclists' crash helmets, although they undoubtedly offered some protection. In reply to a further question regarding facilities in the Department of Scientific and Industrial Research for assisting in the choice of scientific instruments, Mr. Nicholls said that an instrument inquiry service is provided at the British Scientific Instrument Research Association and is largely financed by a contribution from the Association and an equal grant from the Department of Scientific and Industrial Research. Inquiries were at present running at the rate of 2,200 a year. The Research Association had a working party on instrument design which, *inter alia*, reviewed the specification, price and appearance of foreign instruments, and other research associations as well as the Department's research stations also designed new instruments.

Memorial Meeting to Prof. F. Joliot-Curie

A memorial meeting for Prof. Frédéric Joliot-Curie was held at Friends House, Euston Road, London, on January 22. It was attended by many scientists invited by the Association of Scientific Workers and by the National Committee of Science for Peace. The chair was taken by Prof. C. L. Oakley, president of the Association of Scientific Workers, and the speakers were Prof. C. F. Powell, Dr. Pierre Biquard and Prof. J. D. Bernal.

Prof. Powell outlined the contribution made by Joliot and his wife, Irene Curie, towards the discovery of the neutron, leading to the discovery, in 1934, of artificial radioactivity, for which in 1935 he received the Nobel Prize for Chemistry. Dr. Pierre Biquard, secretary-general of the World Federation of Scientific Workers and a close friend of Joliot's, described the joy Joliot had expressed to him at having been able to add to the contribution of French science to man's knowledge. Dr. Biquard also spoke about the part played by Joliot in the French Resistance during the Nazi occupation, when he refused to leave his country and stayed to help defend it after arranging for the valuable stock of heavy water to be brought safely to Britain. Prof. Bernal described Joliot's work on the international level. In the 1930's he had been a member of the Anglo-French Scientific Committee which had laid the basis for the foundation in 1946 of the World Federation of Scientific Workers, of which he became the first president. He had also taken an active part, as a representative of France, in the foundation of Unesco. Later, in 1949, Joliot was chosen as president of the newly formed World Council of Peace, a post which he held until his death.

International Journal of Radiation Biology

International Journal of Radiation Biology and related studies in Physics, Chemistry and Medicine is the full title of a new journal, the first issue of which is dated January 1959 (1, No. 1. Pp. 104. Subscription per volume (4 issues) 75*s*., post paid ; price per part 20*s*. plus postage. London: Taylor and Francis, Ltd., 1959). The editor is Dr. W. M. Dale, of the Department of Biochemistry, Christie Hospital and Holt Radium Institute, Manchester, and to assist him there is a large editorial board with distinguished representatives from Europe, the United States, Australia and Japan; regrettably, the U.S.S.R. is not represented. The first paragraph of the editorial gives a concise description of its aims: "In this new journal we propose to bring together all interests concerned with the biological effects of ionizing radiations. The field we hope to cover will not, however, be a narrow one, for it will embrace any discipline—medicine, physics and chemistry, for example—which has a bearing on our main theme".

The introduction of a new journal invariably arouses mixed feelings. We experience apprehension at the thought of having to add yet another publication to our check list, but on referring to this list, we find, rather surprisingly, that this new journal is the first primarily concerned with the important and growing subject of radiation biology. In the past there has been a tendency to regard radiation biology either as an appendage of radiotherapy or as a highly specialized version of applied physics. These views are completely unjustified and the practitioners of medicine and physics are necessarily joined by radiation chemists, biochemists, cytologists and geneticists in a combined attack upon a highly complex set of problems. The ten original articles in the first issue illustrate this clearly and embrace each of the above-mentioned disciplines. The international scope is revealed by the fact that these ten articles originate from no fewer than seven different countries. Articles may be submitted in English, French or German, accompanied by short summaries in all three languages; all articles in the first issue are, in fact, in English.

Publications in Microform

The problem of providing adequate storage space for the ever-increasing number of publications in science and technology is one that constantly haunts librarians. For journals which may be consulted infrequently and for books of historic importance some form of microform storage appears to be inevitable. The making of the most suitable types of microform materials itself raises problems of mechanics and storage and, for these and other reasons, librarians will welcome the enterprise of Micro-Methods, Ltd., of East Ardsley, Wakefield, Yorks, which has issued extensive lists of journals that have already been issued in micro-card, micro-film or micro-fiche form. Other lists contain details of rare and out-of-print books which have also been produced in microform. Among the many journals available are the *Journal of the Marine Biological Association* (1887–1913); the *American Journal of Psychiatry* (1921–50); the *Japanese Journal of Astronomy and Geophysics* (1922–47); *Jahrbuch über die Fortschritte der Mathematik* (1868–1944); and the *English Historical Review* (1886–1910). Rare books available in microform include Brongniart's "Histoire des Végétaux Fossiles", published in 1828, and Thumberg's "Flora Japonica", published in 1784. A series of theses from the Faculty of Metallurgy at the University of Sheffield is at present being prepared in microform. The charges of Micro-Methods, Ltd., appear to be reasonable and the company would welcome inquiries about the preparation of any publications in micro-form.

Anglo-American Library Associations

In Library Association Pamphlet No. 19, Mr. R. D. MacLeod gives a historical note on the beginnings of the Anglo-American Library Associations (pp. 15. London: Library Association, 1958. 2*s*.), which indicates that even eighty years ago the advantages to be reaped by co-operation were already evident. There is a useful bibliographical note, and apart from its historical interest the paper records an episode to which some parallel could be found a generation later in the matter of chemical abstracting.

University Library, Leeds

The annual report of the Librarian of the University of Leeds for the session 1957–58 (pp. 12. Leeds: Brotherton Library, The University, 1958) records accessions of 15,951 volumes, 3,306 pamphlets and 27,989 periodical parts, an increase of 11 per cent, bringing the holdings to 428,570 volumes and 173,311 pamphlets. Loans to readers totalled 101,220 and inter-library loans 6,041, the number of books lent increasing by 42 per cent. Keeping the library open until 10 p.m. proved an immediate success and has now been introduced on a permanent basis, but there was insistent pressure on seating accommodation and the staff position caused anxiety. The Nuffield pilot survey of library use was completed at the end of 1957 so far as the collection of material was concerned.

City of Leicester Museums and Art Gallery

The annual report of the Museums and Art Gallery at Leicester for the year ending March 31, 1958 (pp. 35+4 plates. Leicester, 1958), which is well illustrated, records difficulties in recruiting senior staff for museum work and also the completion of the reconstruction work on the roof of the main building. This had necessitated the re-designing of the natural history galleries on the first floor. The Schools Department has been able to increase the number of loans of museum material to schools, but the demand still outstrips the supply. A record was achieved in the number of temporary exhibitions shown, and the Saturday evening lectures maintain their appeal.

The Parliamentary and Scientific Committee

The annual report for 1958 of the Parliamentary and Scientific Committee (pp. 26. 1959), presented to the annual general meeting on February 18, includes a list of addresses and discussions held during the year. These dealt with the present and future position of the universities, with special reference to scientific and technological education and research; space satellites; latest developments with regard to the use of thermonuclear energy at power stations, with special reference to *Zeta*; the five-year plan for the development of China's agricultural resources; the work of the Department of Scientific and Industrial Research; veterinary science, its progress and application in Great Britain; international science; exploration in Antarctica, with reference to the International Geophysical Year; the research and development background to the railway modernization programme; and the medical problems of living in the nuclear age. Representatives of the Committee's Technical Education Sub-Committee discussed with the Minister of Education the question of future finance for colleges of advanced technology, and the Committee has also made representations on the appointment of a person with no legal or scientific qualifications as comptroller-general of the Patent Office, and is seeking further information about the disbanding of the Microbiology Group at the National Chemical Laboratory. A memorandum was submitted in May to the Pritchard Committee set up to consider the rating of charities and similar organizations including scientific societies, and in moving the adoption of the annual report on February 18, the chairman, Mr. R. Fort, said that the Committee and the Royal Society were the only organizations from which the Pritchard Committee took oral evidence; its report is expected early in 1959. Mr. Fort also referred to the way in which the Parliamentary and Scientific Committee could promote the integration of scientific disciplines, which he thought was the most probable line of scientific advance, and to the importance of maintaining varied sources for grants for scientific work.

Southern Regional Council for Further Education

The eleventh annual report of the Southern Regional Council for Further Education, covering the year 1957–58 (pp. 36. Reading: October 1958), records rapid progress in the development of technical education and steady growth of courses at all levels throughout the region. Regional procedure for considering proposals to establish new advanced courses operated smoothly and satisfactorily, while the record of developments in colleges in the area continues to be impressive. The Ministry of Education has now taken over from the Regional Council the annual publication of lists of sandwich courses available throughout Britain: List 182 details 263 courses being held in the session 1958–59, an increase of 65 on the previous session. Stress is laid on the importance of financial assistance in the development of such courses and on the need both for financial assistance from industry for its own employees and of co-operation between authorities and industry for others. Progress is reported in the establishment of formal and informal links between technical colleges and secondary schools in the area, and the Council has asked constituent authorities to agree to a new basis for arranging courses for technical teachers. At the request of the Council, the Regional Academic Board has begun a survey to assess the needs of industry in relation to the development of technical colleges, and attempts have been made to form an area group of the British Association for Commercial and Industrial Education. The Board has secured the presence of heads of grammar schools as members of advisory committees. A list of research projects and investigations carried out since 1955 in technical colleges in the region is included.

Science, Philosophy and Religion

THE Eddington Memorial Lectures have come to occupy a special place in the scheme of things, because they enable men of distinction to illuminate some particular facet of the working of that great mind. In his recent lecture entitled "Science, Philosophy and Religion" (pp. iv+31. Cambridge: University Press, 1959. 4*s.* 6*d.* net), Sir Russell Brain shows how the analysis of man, science and revelation, man and mechanization, perception and knowledge fit into the main stream of Eddington's thought; and this because the author is dealing with someone who was all at once Quaker, mystic, mathematician, astronomer and metaphysician. If one lesson emerges clearly from pondering upon Eddington's philosophy, it is that a new concept will be needed to enable us to explain total behaviour in a way which transcends individual components. This is well said for biological systems, but it (or something very like it) is becoming essential for inanimate phases, too, as witness the present discontents with 'classical' quantum theory. Ratiocination will try its hardest, though maybe these regions form part of the unseen world to which, as Eddington says, the human spirit must turn.

Design for Tropical Living

GROWING interest in the effects of environmental factors on life in tropical regions is to be found in the number of conferences and specialist meetings which have been held during the present decade. In 1951 an informal meeting was held in London to discuss co-operative research on building problems arising in hot climates. Unesco has organized two symposia, one held in New Delhi in 1952 to study the application of scientific principles, and one in Uganda in 1955 dealing with geographical factors in relation to the design of tropical buildings in the development of tropical Africa. The United States Building Research Advisory Board arranged a conference in Washington in 1953 on building in hot–humid and hot–dry climates, while in the same year, ecological problems arising from technical developments in tropical and sub-tropical countries were considered at an informal seminar held at Cambridge.

In 1955 medical and other aspects of African housing were considered at a conference under the ægis of the East African Advisory Committee for Medical Research in Nairobi. The Australian Academy of Science held a symposium in Brisbane in 1956 on man and his animals in the tropics, while in September 1958 the Scientific Council for Africa South of the Sahara arranged a specialists' meeting at Lagos on environmental factors affecting the physiology of man. The findings of these and other investigations were brought together during an admirable symposium arranged by the Natal Regional Research Committee of the South African Council for Scientific and Industrial Research and the University of Natal at Durban on October 18, 1957. The papers dealt with the climatic environment, deterioration of materials, physiological aspects of design for tropical living, psychological aspects of life in a warm climate, town and regional planning, climatic control by building, design, air conditioning in the tropics, and architecture in the tropics. These, and the ensuing discussion, have been published in a report (Symposium on Design for Tropical Living. Pp. vii+222. Pretoria, 1958) prepared by the National Building Research Institute of the South African Council for Scientific and Industrial Research.

Report of the Smithsonian Institution

THE annual report of the Board of Regents of the Smithsonian Institution for the year ended June 30, 1957 (cf. *Nature*, 181, 1709; 1958), has now been published as a bound volume (pp. x+499+74 plates. Washington, D.C.: Government Printing Office, 1958. 4.50 dollars) with a general appendix, including memoirs and reports of investigations made by members of the staff of the Institution or collaborators. Among those not previously published or not easily available may be mentioned E. B. Roberts's review of the United States Coast and Geodetic Survey, 1807–1957; Prof. T. Gold's James Arthur lecture, "Cosmic Rays from the Sun"; F. L. Whipple's "Meteors"; J. M. Chamberlain's "The Development of the Planetarium in the United States"; R. Lee's "Jet Streams"; E. B. Leopold and R. A. Scott's "Pollen and Spores and their Use in Geology"; Prof. R. E. Crist's "The Land and People of the Guajira Peninsula"; M. C. Leikind's "Aniline Dyes—Their Impact on Biology and Medicine"; and T. D. Stewart's "Stone Age Skull Surgery". A limited number of reprints of the papers are available on application to the Editorial and Publications Division, Smithsonian Institution.

Rand Corporation Publications

THE Rand Corporation has presented to the Science Museum Library, as a national deposit collection for Great Britain, a set of nearly 1,000 of its research publications. These range through mathematics, physics, electronics, aeronautics, economics, and the social and political sciences. They are now available for loan to all registered borrowers from the Science Museum Library, and to anyone as photocopies through the Science Museum Library Photocopy Service. The Index to the Rand Corporation Publications is held at the Science Museum Library, but is not for loan. Copies of the Index have also been deposited in the larger university libraries of Great Britain.

Design of Office Chairs and Tables

GENERAL principles which may be applied to the design of chairs and tables can be discerned in the results of a number of researches undertaken during the past few decades in several related biological fields. Studies of anatomical structure and function have given information as to where support for the body should or should not be provided. Clinical evidence demonstrates the results of insufficient attention to body mechanics. Studies of the times at which different muscle groups come into play and become fatigued in various activities, and the extent of their action in different positions, indicate the relative physiological efficiency of different working postures. Many anthropometric surveys have now been made with application to a wide variety of practical, industrial and military problems.

From these studies Dr. W. F. Floyd and Dr. D. F. Roberts have selected the findings relevant to the dimensions and design of office chairs and tables and summarized them in a report published by the British Standards Institution (Anatomical, Physiological and Anthropometric Principles in the Design of Office Chairs and Tables. B.S.3044, 1958. 5*s.* net). Among the factors considered are: posture, supporting the trunk weight, seat height, seat depth, seat width, tie rails, trunk stabilization, the backrest and table height. The report contains a bibliography giving details of previous studies in this and other related fields.

Fishing Gear of England and Wales

THE Ministry of Agriculture, Fisheries and Food has recently published a revised edition of the late F. M. Davis's "An Account of the Fishing Gear of England and Wales" (Fishery Investigations, Series 2, Vol. 21, No. 8. Pp. v+165. London: H.M. Stationery Office, 1958. 35*s.* net). Although a new edition of this standard reference work, now twenty-two years old, is to be welcomed, one can only regret that the opportunity has not been taken to bring it thoroughly up to date. Far too much of the book is taken up with descriptions of methods which are of interest only to the historian of fishing—methods which could equally well be found in a library copy of the earlier editions. This leads to an imbalance in the presentation. Thus the description of the Larsen trawl occupies no more space than that of the older (and much simpler) stownet which it has now almost entirely superseded, while the largely derelict fishing weirs, now only a memory to most fishing communities, receive fuller treatment than either. Despite, however, the resulting distortion of the overall picture of British fishing methods, the work remains an invaluable compendium of fishing practice around the United Kingdom.

The Wonderboom

THE famous wonderboom tree of Pretoria has been described as "the most remarkable example of its species in Africa and a National Monument". This magnificent 'tree' nestles against the sheltered north slope of the Magaliesberg range, a few miles north of Pretoria and close to the River Apies. The tree is an evergreen wild fig, *Ficus pretoriae* Burtt-Davy. There are many examples of this species in the district, especially along the northern base of the Magaliesberg range, and fine specimens have been recorded as far west as Marico. The best-known individual tree is the klein wonderboom, which is to be found a quarter of a mile to the west of Wonderboom Poort. The wonderboom is remarkable because of its mode of spread; no other example of this species has been found which has attained such considerable dimensions. The spread resembles that of the strawberry plant, the branches taking root with new trunks growing up until the single tree looks like a miniature forest. In the klein wonderboom thirteen 'individuals' have arisen from the original trunk. From north-north-east to south-south-west the diameter of the tree is about 170 ft. and from east to west about 145 ft. It is at least 74 ft. high. This famous banyan tree is described in a special issue of the *Transvaal Fauna and Flora* (No. 7; 1956), which is devoted entirely to the Wonderboom Nature Reserve.

Respiration of Excised Tomato Roots

IN a further contribution to our knowledge of the carbohydrate nutrition of tomato roots grown in pure culture, D. R. Morgan and H. E. Street have examined the sugars, and sugar phosphates and alcohols, which may serve as respiratory substrates (*Ann. Bot.*, N.S., 23, 89; 1959). The respiratory responses of substrate-depleted excised root tips to a range of sugars, sugar phosphates and sugar alcohols were determined by measuring oxygen uptake by the direct method of Warburg. Sucrose, dextrose and lævulose are the only sugars which promote a high level of oxygen uptake. The effects of azide and dinitrophenyl on the oxygen uptake promoted by sucrose and by dextrose are described. Mannose is a strong inhibitor of respiration. The inhibition is reversed by the simultaneous addition of those sugars which also reverse the growth inhibition caused by mannose. Mannose inhibits the respiration of sucrose and of glycolytic intermediates. Galactose is slowly respired and does not, even at high concentration, inhibit the respiration of sucrose.

Standards of Radioactivity

THE U.S. National Bureau of Standards Circular No. 594, entitled "Preparation, Maintenance, and Application of Standards of Radioactivity", by W. B. Mann and H. H. Seliger (pp. iv+47. Washington, D.C.: Government Printing Office, 1958. 35 cents), is a revision and unification of two review articles originally published in 1956 (*Internat. J. App. Rad. and Isotopes*, 1, 3 and 215; 1956). It surveys the current position in the field of standardization of radioactivity and describes the methods available for the preparation of both primary and secondary standards. The applications of the standards to problems in physics are discussed, including historical and geological dating from half-lives. One section is devoted to a summary of the results of the international comparisons of radioactivity standards which have been made during the past few years, and the circular concludes with an extensive bibliography. The main differences from the original articles are, apart from the inclusion of recent work, the use of a modified Harvard system of references and the incorporation of illustrations showing specifically the methods used at the National Bureau of Standards in the field of radioactivity.

Radio Industry Council Premiums for Technical Writing

THE Radio Industry Council has announced the award of six premiums of 25 guineas each for papers on radio and electronics published during 1958, as follows: "A New High-efficiency High-power Amplifier", in *The Marconi Review*, by V. J. Tyler (Marconi's Wireless Telegraph Co., Ltd.); "New Types of d.c. Amplifiers", Parts 1 and 2, in *Electronic and Radio Engineer*, by D. J. R. Martin (The Mining Research Establishment); "A Survey of Microwave Radio Communication", in *Electronic Engineering*, by W. J. Bray (Post Office Engineering Department); "All Travelling-wave Tube Systems", in *Electronic Engineering*, by S. Fedida (Marconi's Wireless Telegraph Co., Ltd.); "Electronic Developments at Very Low Temperatures", in *British Communications and Electronics*, by Dr. E. Mendoza (University of Manchester); "Analogue Computation", in *British Communications and Electronics*, by E. Lloyd Thomas (R. B. Pullin and Co., Ltd.).

Institution of Electronics Premiums

THE Institution of Electronics is to award the following new premiums for papers accepted for publication in the *Proceedings of the Institution of Electronics* during 1959: The Institution of Electronics Premium (25 gns.) for the most outstanding paper of the year; the Electronic Applications Premium (20 gns.) for the most outstanding paper dealing with the practical application(s) of electronics; the New Electronic Device Premium (15 gns.) for the most outstanding paper dealing with a specific new electronic device; the Institution of Electronics Exhibition and Convention Premium (20 gns.) for the most outstanding paper read at the 1959 Convention and accepted for publication in the *Proceedings*. Further particulars of the regulations governing these awards can be obtained from Mr. W. Birtwistle, Honorary General Secretary, Institution of Electronics, 78 Shaw Road, Rochdale, Lancs.

Carlsberg-Wellcome Travelling Research Fellowships

APPLICATIONS are invited for the Carlsberg-Wellcome Travelling Research Fellowships, 1959–60, the object of which is to encourage co-operation, on an exchange basis, between Danish and British research workers in any branch of the natural sciences which has a bearing upon human and animal medicine. One fellowship annually is awarded to a candidate from the United Kingdom for a year's work in Denmark and one annually to a Danish candidate for a year's work in the United Kingdom. The stipend is in the range £800–£1,200 per annum (or the equivalent sums in Danish kroner), travelling and some incidental expenses being provided in addition. Tenure of the awards will start in September, 1959. Inquiries from candidates in the United Kingdom should be addressed to the Assistant Scientific Secretary of the Welcome Trust, 52, Queen Anne Street, London, W.1. Completed applications must be submitted before April 30.

Institute of Metals: Officers

THE following were recently elected to office on the Council of the Institute of Metals: *President*, G. L. Bailey (director, British Non-Ferrous Metals Research Association); *Past-President*, Lord Tedder (chancellor, University of Cambridge); *Vice-Presidents*, Prof. H. Ford (Imperial College of Science and Technology, London); E. H. Jones (joint managing director, Capper Pass and Son, Ltd., North Ferriby); and Prof. H. O'Neill (University College of Swansea, University of Wales); *Honorary Treasurer*, D. P. C. Neave (director, British-American Metals Co., Ltd., Capper Pass and Son, Ltd., James Bridge Copper Works, Ltd., and Wolverhampton Metal Co., Ltd.).

Society for Analytical Chemistry: Officers

THE following have been elected to office in the Society for Analytical Chemistry for the forthcoming year: *President*, R. C. Chirnside; *Past Presidents serving on the Council*, J. H. Hamence, D. W. Kent-Jones, J. R. Nicholls, K. A. Williams; *Vice-Presidents*, D. C. Garratt, Magnus A. Pyke, J. G. Sherratt; *Honorary Treasurer*, A. J. Amos; *Honorary Secretary*, R. E. Stuckey; *Honorary Assistant Secretaries*, L. Brealey (*Programmes Secretary*), S. A. Price.

University News:

Belfast

THE following appointments to lectureships in The Queen's University of Belfast have been announced: Dr. A. H. Jarrett (applied mathematics); Dr. R. W. J. McCarroll (applied mathematics, digital computing); Dr. M. W. Roberts (physical chemistry); Dr. S. C. R. Dennis (engineering mathematics); A. M. Arthurs (engineering mathematics); B. G. Leary (electrical engineering).

Bristol

A GRANT of £2,075 from the Department of Scientific and Industrial Research to the Department of Physics for research in cosmic rays under Prof. C. F. Powell for the year ending July 31, 1960, has been received. The following have been promoted to senior lectureships from August 1, 1959: D. F. Gibbs (physics); Dr. R. J. Fitzpatrick (veterinary pharmacology).

Leeds

THE following appointments were recently made in the University of Leeds: Dr. A. Ralston, as temporary lecturer in the Department of Mathematics (Electronic Computing Laboratory); Dr. W. Rigby, as lecturer in the Department of Organic Chemistry; Dr. F. H. J. Cornish, as lecturer in applied mathematics.

Sheffield

THE following appointments were recently made in the University of Sheffield: Mr. C. L. Kirk, to be lecturer in the Postgraduate Department of Applied Mechanics; and Mr. M. Cable, to be lecturer in glass technology.

Announcements

DR. E. J. SOLVAY, of Brussels, has been appointed president of the Society of Chemical Industry in succession to Sir Robert Robinson, who will complete his term of office on July 10. Dr. Solvay is a direct descendant of the discoverer of the ammonia soda process which bears his name.

THE Langley Memorial Prize was founded by the friends of the late Dr. W. H. Langley, principal medical officer, Southern Nigeria, to commemorate his work and the services he rendered to Nigeria. The prize, of approximately £21, is open to officers, past and present, of the West African Medical Departments; it is awarded periodically for the best paper on one of the following subjects: (*a*) tropical medicine or surgery; (*b*) tropical hygiene and sanitation; (*c*) tropical entomology and parasitology. Entries for the award in 1959, consisting of either published or unpublished work, should be sent to the Dean, London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1, not later than October 1.

APRIL 22 is the twenty-first anniversary of the foundation of the British Coal Utilization Research Association. To mark the occasion the Association is throwing its laboratories open to inspection during April 22–24. On April 22, which is to be a private members' day, the proceedings will be opened by the Rt. Hon. Lord Mills, Minister of Power. Further information can be obtained from the Assistant to the Director-General, B.C.U.R.A., Randalls Road, Leatherhead, Surrey.

THE Clay Minerals Group of the Mineralogical Society is holding a meeting on Clay Minerals and Industry in Sheffield on April 15 and 16. Further information can be obtained from Dr. R. M. S. Perrin, School of Agriculture, The University, Cambridge.

THE X-ray Analysis Group of the Institute of Physics is holding a conference on Clay Minerals and Biological Fibres in the School of Chemistry, University of Leeds, on April 17 and 18. Further information can be obtained from the honorary secretary of the Group, Dr. R. C. Gordon, Safety in Mines Research Establishment, Portobello Street, Sheffield 1.

THE CARNEGIE INSTITUTION OF WASHINGTON

REPORT FOR 1957–58

YEAR BOOK 57 of the Carnegie Institution of Washington* includes the President's and departmental and administrative reports for the year July 1, 1957–June 30, 1958, together with a bibliography of publications. Reviewing the work of the Institution, the president, Caryl P. Haskins, recalls that the year marked the tenth anniversary of the dedication of the 200-in. Hale telescope on Mount Palomar and of the joint operation of the Mount Wilson and Palomar Observatories by the Carnegie Institution of Washington and the California Institute of Technology. Both the presidential and the departmental reports briefly survey the work of the decade and the important advances in knowledge, particularly in our ideas of the size of the observable universe, the magnitudes of the distances within it, and its age, and in our knowledge of stellar evolution.

During the year the magnetic classification and study of sunspots and related phenomena continued, and a series of direct photographs of the bright comet Mrkos (1957*d*) was obtained with the 48-in. Schmidt telescope. An extensive project on the chemical composition of stellar atmospheres is in progress and a survey of high-dispersion spectra of the early carbon stars has revealed differences in both the line and the band spectra. Coudé spectrograms with a resolution of 10 A./mm., or better, are being accumulated to obtain evidence bearing on mass loss from late-type giants and super-giant stars, and the investigation of the internal motion of nebulæ using the multislit technique and a dispersion of 4·5 A./mm. at the 200-in. coudé continued. Work on the colour-magnitude diagram of the Draco system showed that the diagram is of the same type as that of the globular clusters of the galactic halo and conforms to the rule that large numbers of cluster-type variables can only be expected if the horizontal branch on the red side of the variable gap is strongly populated. The direct photography of multiple galaxies continued, and also the investigation of objects which might be associated with radio sources. A theoretical investigation was conducted by the properties of the very luminous *OB* stars observed by Code and Houck, and a preliminary model of a photoelectric spectrum-scanning device was tried on the coudé spectrograph of the 100-in. telescope. The Committee on Image Tubes for Telescopes has continued to encourage the development of photoelectric image-intensifying devices for use in astronomy, directing attention both to methods that record the photoelectrons themselves and to methods that use photoelectrons to produce an optical effect.

The Department of Terrestrial Magnetism continued its study of the emission of energy at radio frequencies from celestial objects, but solar activity of unprecedented magnitude interfered seriously with optical red-shift measurements of the far-distant galaxies at Mount Wilson and Palomar, although work proceeded rapidly on precision equipment designed to measure the position of radio sources to within a few square minutes of arc. The density distribution and velocity distribution of atomic hydrogen gas clouds in our galaxy continued to be of major interest to the radio astronomy group, while three noteworthy projects were carried forward as part of the programme of the International Geophysical Year: the study of the intense band of electric current, called the electro jet, that circulates in the upper atmosphere in the region of the Earth's magnetic equator; a study of the Earth's crust in the Andean highlands at more than 200 sites, utilizing explosions normally set off in operating large open-pit copper mines; and the measurement of the ages of rock minerals through the methods provided by the study of radioisotopes, notably the geographical patterns of the ages of Precambrian rocks in North America, particularly the metamorphic Precambrian rocks of the central and southern Appalachians. A general picture of the geological history of the Appalachian orogenic belt has emerged.

The Geophysical Laboratory has constructed new equipment of rather revolutionary design for studying geochemical and geophysical phenomena: with a new 'single-stage' apparatus, pressures of up to 50,000 atmospheres at temperatures up to 1,700° C. have been achieved, and in the two-stage design, in which the piston of the single-stage apparatus is supported, up to 65,000 atmospheres at 1,100° C. The single-stage apparatus is being used to study the influence of pressure on the melting-points of minerals that might exist 80 miles below the Earth's surface. Work on mineral assemblages in the Green River formation, on the beneficial effect of potassium on soils contaminated with strontium-90, on the effect of water on the melting of silicates and on the biotites is reported in some detail, as well as work on feldspar, ore minerals of the sulphide type and on the diffraction effects of short-range ordering in layered sequences. In crystallography the magnetic structure of chalcopyrite has been determined by neutron diffraction studies and a crystallographic study was made of arsenopyrite by X-ray diffraction methods.

Five of the Institution's seven departments are concerned with biological investigations of one kind or another. The Geophysical Laboratory, for example, has investigated the detection of organic materials in Precambrian rocks and has significantly increased the yields of organic materials from processed shales such as Swedish Kolm shale (Cambrian), Nevadan Vanini shale (Ordovician) and Colorado Green River shale (Eocene). In the Biophysics Group of the Department of Terrestrial Magnetism attention has been focused particularly on the critical importance in metabolism and growth of the elaborate and precise fine structure of many of the constituents of the living cell. The properties of the ribosomes and the kinetics of their formation have been studied by ion-exchange columns, radioactive-tracer methods and the 'Spinco' Model *L* centrifuge. Work with *Escherichia coli* is described in some detail, while, besides studies on virus purification, extensive work on amino-acid analogues continued with particular emphasis on determining whether the analogues are contained in radically different molecular species or in proteins similar to those normally synthesized.

* Carnegie Institution of Washington. Year Book No. 57, July 1, 1957–June 30, 1958. Pp. xi+497+12 plates. (Washington, D.C.: Carnegie Institution, 1958. 1 dollar, paper bound; 1.50 dollars, cloth bound.

Measurements in the Department of Plant Biology on the derivative absorption spectra of chlorophyll in numerous algae and other plants suggest that there are more than two forms of chlorophyll *a*. Further investigation on the photochemical formation of chlorophyll in leaves from its precursor photochlorophyll gave yields of about 0·5–0·7 molecule of chlorophyll formed per quantum of light absorbed, suggesting that two quanta of light may produce one molecule of chlorophyll. A study of the reversible oxidative bleaching of chlorophyll by chemical treatment and by light in several species of photosynthetic bacteria showed that the chemical properties of the pigment are markedly influenced by its incorporation in natural structures, the form absorbing light at the longest wave-length (890 mμ) being the most active. A number of climatic races of *Mimulus* plants are being grown for laboratory studies of the way their rates of respiration respond to variations of temperature and intensity of light, and studies have been commenced on the germination of seedling populations of contrasting parental and hybrid lines of *Mimulus* under crossed gradients of controlled temperature and light intensity.

In the Department of Embryology, studies of the molecular basis of rhythmic motility in spermatozoa indicated that the mechanisms of contractility and co-ordination can be disengaged experimentally. Important findings are reported in work on the development of the adrenals and sympathetic paraganglia in insectivores, and studies on the synthesis of the muscle proteins actomyosin and myosin in the regenerating limb of the salamander continued. Other work was concerned with differentiation and morphogenesis in the human embryo, the neural crest and its derivatives, the chemical basis of morphogenetic movements, the acquisition of biological specificity, the effect of hormones in developmental systems, and the anatomy and physiology of the uterus and the placenta.

In the Department of Genetics, studies with maize clarified an obscure aspect of the suppressor–mutator system of control of gene action, and analyses of biological ultrastructure by methods combining cytochemistry and electron microscopy offered new evidence that the chromosomes in actively dividing cells contain ribonucleic acids at all stages of the mitotic cycle. Studies of the intracellular deoxyribonucleases were concentrated on ascertaining the best procedures for extracting and purifying the intracellular deoxyribonuclease of salmon testes. Further studies of the properties of phage *T*2, which grows on strain *B* of *Escherichia coli*, suggest that phage particles are made from at least two protein sub-units, each containing a large fraction of the total phage sulphur. Studies of bacterial genetics with *Salmonella typhimurium* and *Escherichia coli* support the assumption that recombination among five genetic markers in the former is accomplished through a 'copy-choice' mechanism governing the exchange of characters between a recipient chromosome and a transducing element, and that the frequency of 'switchovers' in this process depends on the genetic constitution of the chromosome regions. Evidence has been obtained that transduction by bacteriophage lambda of loci concerned with galactose utilization in *E. coli* is a matter of lysogenization by a new type of genetic structure, which is part phage and part bacterial in origin.

The Department of Archæology completed its work during the year, and both the departmental and the presidential reports review broadly its work over more than fifty years. Some notes on ceramic studies in Yucatan and a ceramic technology are included in the departmental report.

THE NATIONAL RESEARCH DEVELOPMENT CORPORATION

REPORT FOR 1957–58

THE report of the National Research Development Corporation for the year ended June 30, 1958*, records a revenue from inventions of £174,242, notably from triiodothyronine, Prof. R. L. Wain's phenoxybutyric acid weed-killers, the Bailey bridge, the Royal Aircraft Establishment fire and heat detector and gyroscopic control apparatus for aircraft, the Ministry of Supply electrical ignition system and exploder, anti-thyroid compounds, the Hutchinson–Scarrott pulse height analyser, hecogenin from sisal, the Denny–Brown ship stabilizer control gear, nisin and anti-tumour agents of the nitrogen mustard type, on which all significant expenditure has ceased. Further reference is made to the Corporation's part in the development of electronic digital computers, including a project for the development of a large business-type computer and data-processing system of advanced design and performance, making extensive use of transistors, and two projects for magnetic type equipment for use with digital computers, but progress with the development of a very high-speed computer has been slow. An agreed programme of research and development of computer-controlled machine tools was initiated at the Manchester College of Science and Technology in January 1956, and interesting results are being obtained on the performance of slideways and on the cutting forces occurring during contour milling operations. Work continues on the development of high-performance drive systems, but the Corporation now considers that the time has come to withdraw its financial support.

Work at the National Physical Laboratory on Sir Thomas Merton's diffraction grating inventions is proving important in unexpected ways, and the Corporation's intervention in the development of printed electrical circuits has also been fully justified by results. The Corporation has now been able to retire from the collaborative effort it initiated seven years ago, leading to the collection of pituitary gland and production of adrenocorticotropic hormone on a commercial basis. Development of a process for producing aldosterone in significantly greater quantities from adrenal glands, including a limited amount of aldosterone and other adrenal hormones labelled with tritium, is also being financed, as well as a project for the isolation from *Pueraria mirifica*, from Thailand, of the œstrogenic substance, 'miroestrol', and elucidation of its structure, with the view of ultimate synthesis and medical use.

---

* National Research Development Corporation. Report and Statement of Accounts for the year 1st July, 1957, to 30th June, 1958. Pp. ii+28. (London: H.M. Stationery Office, 1958.) 1*s*. 6*d*. net.

The four prototype groundnut harvesters shipped to East Africa in the spring of 1958 operated well on the true bunch varieties for which they were designed, but some difficulties were encountered in handling semi-bunch varieties, and commercial applications have been established for flexible barges of 40 to 1,000 tons capacity for transporting oil and other liquids by water. Among the new projects, some of which the Corporation proposes to attack under the extended powers confirmed by the 1954 Act, are a cotton-spinning project at the British Cotton Industry Research Association; a continuous-flow laundering project at the British Launderers' Research Association; a programme on ferroelectric ceramics at the Battersea College of Technology; the development of Prof. J. McGee's new form of image intensifier at the Imperial College of Science and Technology; the National Institute of Agricultural Engineering's jute ribboner; and an ultrasonic flow-meter at the British Scientific Instrument Research Association.

Government departments and research councils assigned patent rights in 86 cases compared with 105 in 1956–57, 49 of the total of 147 coming from the universities and eight from private firms and individuals in the United Kingdom, compared with 26 and 3, respectively, out of 148 in 1956–57. Of 612 inventions communicated to the Corporation during the year, compared with 631 in 1956–57, 231 were from Government departments and research councils, 13 from official organizations, four from charitable organizations and 286 from private firms and individuals, 265 in the United Kingdom. Holdings of British and foreign patent applications totalled 2,930, including 370 United Kingdom applications and 595 granted patents, 975 overseas applications and 990 granted patents.

FIGURAL AFTER-EFFECTS

PETER McEWEN'S monograph supplement to the *British Journal of Psychology*, entitled "Figural After-effects" (Monograph Supplement 31; 1958), is a timely summary of research and theorizing in a rapidly growing field of experimental psychology. The fundamental facts are relatively simple and universally accepted; they were first observed by the American psychologist, J. J. Gibson, who found that subjects who had inspected a curved line for some time would afterwards see a straight line as curved in the opposite direction. This discovery aroused relatively little interest until it was taken up by one of the great figures of psychology, Wolfgang Köhler, who had been one of the founders of the *Gestalt* school. He showed in a wealth of detail that almost any kind of visual or tactual perception produced certain effects of a relatively lasting character, effects which would change subsequent perceptions and which could be measured by the amount of such change induced. Most of his work was concerned with visual stimuli, but he also initiated experiments in kinæsthetic figural after-effect, and other sense modalities have also been studied since. It was Köhler who coined the term 'figural after-effects' by which these phenomena are now known.

Köhler did more than this, however. He proposed a physiological theory of the origin of these phenomena, making use of the concept of electrotonus, and deducing the observed phenomena from this theory. In recent years this has led him right over into the physiological field, where his vigorous and unorthodox approach has caused a good deal of discussion and criticism. Within the psychological field, however, he did one further great service by pointing out that his general theory could serve to explain many previously unrelated phenomena, such as the disappearance of certain visual illusions with time, and by suggesting that there were certain very striking similarities between the satiation process, which he believed to underlie figural after-effects, and certain inhibitory phenomena well known in the field of learning and conditioning. Köhler's theory therefore holds out an exciting prospect of unification of large areas of psychology which hitherto had been treated as quite separate from each other; this fact alone would justify the great amount of work that has gone into the testing of his hypotheses.

Dr. McEwen traces all this work, both on the experimental and theoretical level, in a painstaking, accurate and detailed account which is always judicious and remains close to the facts. He shows how much of the work that has been reported suffers from being purely phenomenological rather than quantitative, and how this lack of quantification has made any decisive type of experimentation or theorizing extremely difficult. To take but one example, after-effects are sometimes said to disappear after a few minutes, while at other times they are said to last for days or even months. McEwen also shows very clearly how complex the phenomena under consideration are, and how many of them require *ad hoc* hypotheses to be brought under the wing of Köhler's theory—or indeed that of the only rival theory, advanced by Osgood and Heyer.

It would probably be true to say that concentration on *apparently* unimportant issues and laboratory investigations of problems of theoretical interest characterize a maturing science, whereas exclusive preoccupation with direct practical questions is often characteristic of a pre-scientific stage. Similarly, the emergence of broad general theories covering a large amount of ground, and unifying many diverse phenomena, is also characteristic of a stage of relative maturity in a science, as compared with the purely empirical *ad hoc* investigation of unrelated phenomena. Learning theory was the first part of psychology to achieve such a level of maturity, and Köhler's work may now be said to have achieved the same status for perception. Indeed, the fact that he was able to point to very striking similarities between phenomena in perception and in the learning field suggests that an even greater unification may be in prospect. The whole situation is an exciting and promising one, and inevitably reminds one of those halcyon days in atomic research when interest was still confined to Bohr's model and Heisenberg's principle. The debt which psychology owes to Köhler had already been a large one before he investigated figural after-effects; his work in this field has almost certainly made him one of the greatest figures in psychology. It is curious and a little piquant to realize that the concepts which Köhler uses to account for figural after-effects are similar in many ways to those used by Pavlov to account for the facts of conditioning. That this should be so, in spite of the fact that not so very long ago Köhler and his colleagues founded the *Gestalt* school as an express antithesis to Pavlov's 'atomistic' and associationistic theorizing, illustrates the relative unimportance of the critical parts of the contribution made by schools in psychology, and the much greater importance of their positive and experimental contributions. We have fortunately now left behind to a large extent this era of rivalling schools, and it is fortunate that Köhler survived into and indeed partly originated this new period. The reader interested in the history of science can do no better than read through Dr. McEwen's monograph to discover both the promise of the present situation and also the severe birth-pains to which it is giving rise.

H. J. Eysenck

IRON ORE IN THE SOVIET UNION

"THE iron ore deposits of the Kursk magnetic anomalies, both as regards their concentration and their quality, have no rivals in the world"—so writes P. Y. Antropov, the Minister of Geology in the U.S.S.R. (*Priroda*, 7, 16; 1958). Magnetic anomalies were first discovered during a topographic survey in the region of Kursk in 1783. Before the 1917 revolution, E. E. Leist, professor in the University of Moscow, made a careful survey of magnetic anomalies and concluded that they are due to the presence of magnetite ores at great depths below the cover of sedimentary rocks. The results of the 1919–26 survey were rather disappointing; only rather poor iron ores were found and at a considerable depth. Renewed explorations during 1930–34 and the construction of an experimental shaft (flooded and ruined in 1938) revealed rich ore, but again at a great depth and in a very difficult geological setting. Exploration, on a much wider scale, was resumed after the Second World War. This detailed survey revealed two important features of the geological structure of this region:

(1) Below a cover, varying in thickness from 40 to 500 m. or more, the pre-Palæozoic floor revealed a gigantic anticlinal fold, or rather a packet of such folds forming a belt about 150 km. × 250 km. in extent stretching in a north-west–south-east direction, with the line Orel–Kursk–Belgorod as its diagonal. This pre-Palæozoic massif was buried under a cover of Palæozoic, Mesozoic and Tertiary sedimentary rocks, and was made of Proterozoic schists, ferruginous quartzites and gneisses.

(2) The rich iron ore was not found among the Proterozoic ferruginous quartzites but in a secondary iron ore formed as a crust of weathering immediately above the Proterozoic floor. This secondary iron ore was formed through an almost complete leaching out of silica from the ferruginous quartzites and a transformation of magnetite into martite (hæmatite pseudomorphs after magnetite). The maximum thickness of this ore deposit occurs in the Belgorod district, where it reaches 350 m. Elsewhere, it varies from 30 to 50 m. The best-quality ore occurs in the Yakovlevsky district, where it contains on average iron 61·4 per cent, silicon 5 per cent, sulphur 0·1 per cent and phosphorus 0·02 per cent.

The reserves of ores in the Belgorod region alone are 12 milliard tons, that is to say, five times the reserves of the Krivoy Rog iron ore deposit, until now the largest known in the U.S.S.R. The total reserves of the iron ores in the region of the 'Kursk magnetic anomalies' may be as high as 15–20 milliard tons.

The winning of these ores has already begun by means of shafts and open-cast quarries in the Lebedinsky, Mikhailovsky and Yakovlevsky districts. Thus in the Lebedinsky district the open-cast extraction amounted to 6 million tons in 1956; the Mikhailovsky district is planning to extract 6½ million tons per annum, and the Yakovlevsky district 15 million tons. Thus the total production of these three districts by 1966 is estimated at 27½ million tons per annum. These figures suggest that the total extraction of rich iron ore in the whole region may be estimated at 70–80 million tons per annum. This amount of ore would correspond to 30–35 million tons of cast iron per annum.

In this connexion it is important to note that in 1957 the total production of iron ore in the Soviet Union was 84·2 million tons and the total production of cast iron 37 million tons per annum.

S. I. Tomkeieff

EMPLOYMENT OF SCIENTISTS AND TECHNOLOGISTS IN THE UNITED STATES

ACCORDING to a preliminary report from the National Science Foundation, American industry in January 1957 employed 738,000 engineers and scientists (about two-thirds of all those in the United States), of whom 58,000 were employed as administrators of scientific and engineering activities. The largest occupational group was 528,000 engineers, chemists (72,000) coming next, followed by medical, agricultural and biological scientists (16,600), geologists and geophysicists (14,200), physicists (12,100), mathematicians (12,400) and metallurgists (10,800). Of the total, 92,900 were employed in the electrical equipment industries, 84,900 in the aircraft and parts industry, 79,200 in chemicals and allied products industries, 74,100 in machinery, 50,700 in petroleum products and extraction, 30,200 in fabricated metal products and ordnance, 29,500 in primary metals, and 24,600 in the professional and scientific instruments industry; 29,000 more chemists were employed in chemical industry than in any other industry.

Almost one-third (228,000) of these engineers and scientists were engaged in research and development, and two-thirds of these were employed in the aircraft, electrical equipment, machinery or chemical industries. Nearly three out of every five physicists, but fewer than one out of three of the engineers, mathematicians and biological scientists and two out of every five chemists were engaged in research and development. Nearly 600,000 technicians worked with scientists and engineers in all activities, and of these, 160,000 were engaged in research and development, the largest numbers in the electrical equipment, aircraft, machinery, chemical and fabricated metal parts and ordnance industries. During 1954–57 employment of engineers rose by 27 per cent, of chemists by 16 per cent and of biological scientists and physicists by about 60 per cent. In these three years 70,000 first degrees in engineering were awarded by American engineering; the proportion of engineers and scientists employed in research and development rose from 28 to 31 per cent, and employment in such activities rose by more than 45 per cent, whereas in the same period research and development costs rose from 3,700 million to 6,400 million dollars.

CHEMOTHERAPY OF PARASITIC DISEASES

A MEETING of the Parasitology Group of the Institute of Biology was held at the Institute's rooms in London on October 24, when two speakers were invited to read papers on the chemotherapy of parasitic diseases.

Dr. Ann Bishop (Molteno Institute, Cambridge) described some aspects of resistance to drugs in parasitic Protozoa. The fact that parasitic organisms can become resistant to drugs in the course of the therapeutic treatment of the host was discovered in Ehrlich's laboratory, early in the present century, by Franke and Röhl while studying the effect of parafuchsin upon *Trypanosoma brucei* in mice. Trypanosomes have since been made resistant to a wide variety of chemical compounds.

The fundamental problems in the study of resistance to drugs are the nature of the changes which organisms undergo in becoming resistant and the means by which these changes are brought about. In trypanosomes, resistance to drugs may be associated with changes in permeability and with changes in the enzymes present in the cells. Drug resistance in these organisms may be a very stable character and persists after the transmission of the parasite through the insect vector. The spontaneous development of resistance, in the absence of the drug, has been described both in trypanosomes and in *Toxoplasma gondii.*

Malaria parasites also can be made resistant to certain compounds, including proguanil and pyrimethamine, which are used in the treatment of the disease. Resistance persists after transmission of the parasite through the insect vector, in which, unlike trypanosomes, the malaria parasite undergoes a sexual cycle of development.

A study has been made of the development of resistance to metachloridine (2-metanilamido-5-chloropyrimidine) in pure lines of *Plasmodium gallinaceum* in chicks. No difference in the rate of development of resistance was observed in these lines. The rate of development of resistance was not related to the size of the dose of drug, but was affected by the size of the inocula producing the infections exposed to the action of the drug. The suddenness with which resistance appeared in some of the strains studied, and its stability in the absence of the drug and after the sexual development of the parasite, suggested that it arose by mutation, the mutation being of a low frequency.

Dr. O. D. Standen (Wellcome Laboratories of Tropical Medicine, London) outlined an approach to the experimental chemotherapy of helminthiases. The diseases of man and animals caused by the presence of helminth parasites are particularly important in the tropics, and are often responsible for the low level of efficiency and uneconomic production of stock animals in rural areas. The eventual control of these helminthiases will depend on a fuller knowledge of their epidemiology, but also presents problems which can only be resolved by the use of drugs.

The number of even moderately efficient anthelmintics in use at the present time is small, and most are toxic to the host. There is thus an urgent need for drugs which could be used in mass treatments of man and animals.

The discovery of new drugs requires the close collaboration of biologist and chemist. Two methods of approach may be used. An empirical method is one whereby large numbers of compounds of unknown activity are tested, in order to determine their effects on the parasite. The selective approach is one in which chemicals of known anthelmintic potency are modified in order to improve their action, and this method may be used with substances discovered by the empirical method. The ultimate aim is to discover the relation between the molecular structure of the drug and its anthelmintic activity and toxicity to the host.

The selection of helminths to be cultured in laboratory animals is of great importance. The number which can be cultured in this way is small, and of these the species pathogenic to man and animals are few. It is thus necessary to test drugs using helminths which are the natural parasites of laboratory animals. The successful maintenance of a parasite in all the stages of its life-history in laboratory animals often requires a long period of fundamental research before a sufficient supply of material is assured for routine investigations, for which an abundance of material is required since hundreds or even thousands of tests may be necessary before an effective drug is discovered.

The use of a multiple helminth screen, employing a wide range of species living in different habitats, yields interesting results. Thus, basic work with *Aspicularis tetraptera* in the mouse has contributed materially to the development of piperazine for the treatment of ascariasis and oxyuriasis. More recent chemotherapeutic tests, against *Nippostrongylus muris* in the young rat, provided the basis for the development of salts of bephenium that are efficient in the treatment of nematodiriasis in sheep and ancylostomiasis in man and dogs.

The experimental chemotherapy of helminthiases necessarily demands many species of helminths in all stages of their development and this offers an unparalleled opportunity for concurrent research into the structure and life-cycles of the parasites, into their biochemistry and host–parasite relationships and into the mode of drug action. While such studies may be an end in themselves, they also provide the only basis for a rational approach to chemotherapy.

In opening the discussion, Dr. H. O. J. Collier (Department of Pharmacological Research, Parke, Davis and Co., Ltd., Hounslow) said that the history of practical chemotherapy began with the treatment of parasitic diseases. Experimental chemotherapy also started in this field. In 1891 Ehrlich and Guttmann (*Berl. Klin. Wsch.*, 28 (9), 953; 1891) showed that methylene blue is a fairly potent antimalarial agent. Choosing this dye because it stained the malaria parasite within red corpuscles and because it was of low toxicity to man, Ehrlich, with Guttman's help, treated with it two sufferers from malaria and achieved immediate success. Later, Ehrlich had to test hundreds of compounds to achieve '606' and did not screen at random but approached his objective by steps, basing each new compound on results obtained with previous ones.

Work described in the preceding papers follows on the experimental chemotherapy started by Ehrlich. Each speaker was mainly concerned with one major problem, well known to Ehrlich and his colleagues; Dr. Bishop with resistance to drugs, and Dr. Standen with specificity of interaction between chemical and biological species.

Some of the ways in which drug resistance can develop were described. Compared with a sensitive organism, a resistant form may absorb a drug less, excrete it faster, destroy it more effectively, produce more of the drug's antagonist or possess a route of biosynthesis alternative to that blocked by the drug. These differences may depend on modifications of enzyme systems; an understanding of these would lead to a better understanding of drug resistance.

Problems of specificity are at the heart of chemotherapy, because if drugs were not more toxic to one species than to another, selective poisoning would be impossible. The differences in responses of various species to the same compound provide difficulties, however, because related species cannot be relied upon to respond in the same way to a new substance, and the second paper explained how the experimental chemotherapist deals with this dilemma.

Another aspect of the use of chemotherapeutic agents was mentioned by Dr. S. Kendall, in reference to coccidiosis of fowls. Drugs are added to feed in order to determine whether they are toxic to the parasite or whether resistance is developed. Results, so far, show these drugs to have a coccidiostatic action, without elimination of the parasite. Dr. L. Joyner said that this posed the general problem as to whether eradication of the parasite was necessary; in the case of flukes, for example, it was desirable. However, in some protozoan infections, it is preferable to induce a state of premunition in the host, or one of immunity induced by stages in the life-cycle other than the pathogenic one. Dr. J. Leiper said that some anthelmintics effective over a wide range may produce curious results, some parasites being killed and others encouraged. Thus, in the use of chemotherapeutic agents the habitat of the parasite within the host may be as important as the specific action of the drug. Dr. Standen replied that the range of activity of the drug must be carefully tested. Dr. C. Hopkins pointed out that the mode of action of the drug is unknown, a situation complicated by the difficulties of cultivation of parasites *in vitro*. Anthelmintics can act by blocking the metabolism of the worm, not necessarily causing a complete 'knock-out' reaction, and the site of the parasite within the host might indicate specific substances required from the host by the metabolism of the parasite.

The proceedings of this meeting will not be published in full. June Mahon

A PRESUMPTIVE HUMAN XXY/XX MOSAIC

By Dr. C. E. FORD
Medical Research Council Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell, Berks
AND
Dr. P. E. POLANI, J. H. BRIGGS and Dr. P. M. F. BISHOP
Guy's Hospital, London Bridge, S.E.1

THE discovery of 'sex chromatin' by Barr and Bertram[1] and the subsequent recognition of its regular occurrence in normal females of many mammalian species (including man) has provided a new approach to the study of human intersexual conditions, the value of which is demonstrated in the proceedings of a recent symposium[2]. Although the presence of sex chromatin is generally taken to be diagnostic of an *XX* individual, this is not proved, and the unequivocal determination of the sex chromosome constitution can only come from the direct study of the chromosomes themselves.

A technique for obtaining chromosome preparations from biopsy specimens of bone marrow has recently been described in outline and used in the study of one 'chromatin-positive' case of Klinefelter's syndrome[3]. (Klinefelter's syndrome is a variable clinical syndrome in somatically male individuals who are sterile, generally with azoospermia, often with gynæcomastia and endocrine defects, but essentially and always with small testes after puberty.) The few cells from this first case seen in metaphase contained chromosomes indistinguishable from those of a normal female. Recently we have been able to examine the chromosomes from two further cases of this syndrome. One, chromatin-negative, had the chromosomes of a normal male. The second, chromatin-positive, gave an unexpected result and is the subject of this article.

A marrow specimen was obtained by sternal puncture at Guy's Hospital, converted into a suspension there and immediately sent to Harwell for cytological processing. The final preparations contained a satisfactory number of cells in mitotic metaphase, although many of them were unsuitable for accurate observation owing to supercontraction of the chromosomes, or separation of the chromatids at the centromeres, or both. Sixty-five cells were accepted as suitable for counting, and the results are summarized in Table 1. In ten cells, including those recorded as containing 48 and 49 chromosomes, there was an uncertainty of one, or two, chromosomes. The method of counting (to minimize subjective bias) and the errors to which the recorded counts are liable have been discussed previously[3,4].

Table 1. COUNTS OF CHROMOSOMES IN 65 CELLS. KLINEFELTER'S SYNDROME (CHROMATIN-POSITIVE)

No. of chromosomes	41	42	43	44	45	46	47	48	49
No. of cells	1	0	0	2	3	13	44	1	1

We have not yet succeeded in identifying the individual X and Y chromosomes, although it has been reported that Y is distinguishable from other similar chromosomes in preparations made from cells in tissue culture[5]. Nevertheless, it is possible to identify sex cytologically by classifying the chromosomes into four clearly defined groups[3]: (1) the shortest chromosomes have nearly terminal centromeres; there are four in the female, five in the male; (2) the next longer ones form a mixed group; there are sixteen in both sexes; (3) the medium-length chromosomes have sub-median or sub-terminal centromeres; there are sixteen in the female, fifteen in the male; (4) the longest ten chromosomes are well differentiated and form five easily recognized pairs that are the same in both sexes. It follows that Y is a short chromosome with a nearly terminal centromere and that X is a medium-length chromosome with a sub-median or sub-terminal centromere. This is in accord with observations on the sex chromosomes bivalent at metaphase in first spermatocytes[6].

Twelve of the cells with 47 chromosomes from the present case were selected for detailed analysis. All were found to contain five very short acrocentric chromosomes plus sixteen other short chromosomes (as in a male) and sixteen chromosomes in the medium-length group (as in a female). The remaining ten chromosomes were the five long pairs common to both sexes. An example is shown in Fig. 1. The obvious interpretation is that these cells contain two X-chromosomes and one Y-chromosome, in addition to the normal 22 pairs of autosomes, although the possibility that they are basically female and trisomic for one of the small acrocentric autosomes is not excluded. In so far as the 47-chromosome cells are concerned, our case is therefore parallel to that described very recently by Jacobs and Strong[7].

An attempt was made to classify the chromosomes in all thirteen cells with counts of 46. This was possible in eleven cells, although not all were of equal technical standard. Five of them contained an apparently normal female set with *four* small acrocentrics, sixteen other short chromosomes, sixteen medium-length and ten long chromosomes. There were points of uncertainty in the remaining six cells, but at least three of them probably had the same constitution. We therefore believe the case to be an instance of true mosaicism, notwithstanding the likelihood that some counts of 46 may represent damaged cells that originally contained 47 chromosomes. In the first place, there are many more cells with a count of 46 than would be expected (in our experience) from damage alone; and secondly, the chance of loss of one of the same group of five chromosomes from at least five, probably eight, and possibly more of the eleven cells must be very low indeed.

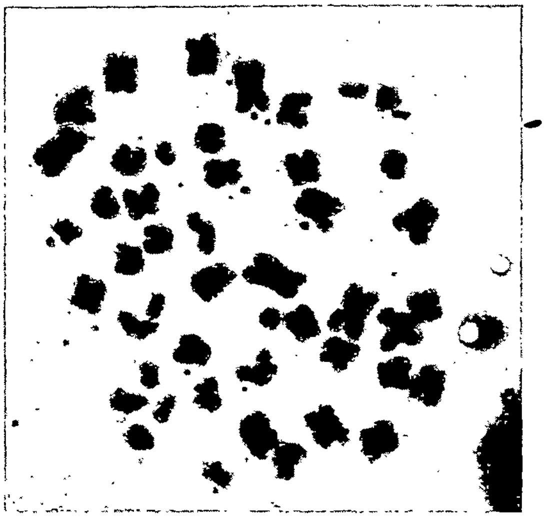

Fig. 1. Cell in metaphase with 47 chromosomes (presumptively XXY plus 44 autosomes) from the bone marrow of the patient with Klinefelter's syndrome (chromatin-positive). Feulgen squash after colchicine pretreatment. (× 2,220)

Granted that the 47-chromosome cells are XXY and the case is a true mosaic, it is most reasonable to suppose that the 46-chromosome cells arose through loss of the Y-chromosome by mitotic non-disjunction. It is known that clones of reticular cells, characterized by one or more visible chromosome rearrangements, may appear during the regeneration of the bone marrow in irradiated mice[8,9]; and recent evidence has shown that in certain circumstances they may proliferate differentially even to the extent that one clone is disseminated widely and outgrows all the rest (Ford, C. E., Micklem, S., and Gray, S. M., unpublished work). There is also evidence that marrow cells deficient in chromosome segments produced by irradiation of normal animals are very rapidly eliminated (Sharman, G. B., unpublished work). Now, loss of the Y-chromosome from an XXY cell would be a step in the direction of *normality*, and such cells might therefore exhibit a small selective advantage relative to their progenitors; on the other hand, loss of an autosome would yield a deficient cell, which, if it did not die, would not be expected to multiply. We therefore assume that the 46-chromosome cells contain two X-chromosomes and no Y-chromosome, that is, contain the normal female complement.

The supposition is that the mosaic patient developed from an XXY zygote and that this arose from fertilization of a non-disjunctional XX egg by a normal Y sperm, or of a normal X egg by a non-disjunctional XY sperm. The occurrence of one non-disjunctional type immediately suggests that others may be found. These could include XXX, $X0$, $Y0$, and possibly XYY types; some of them have indeed been postulated to exist on various grounds. Of these, perhaps, the most likely candidate is $X0$ for chromatin-negative cases of Turner's syndrome[10]. The occurrence of an individual with Klinefelter's syndrome and one with Turner's syndrome in the same sibship[11] is readily explained on such a basis, since the two syndromes would represent complementary zygotic types and could appear as a result of habitual non-disjunction of the sex chromosomes in a parent during maturation of either the ova or the sperm.

The *Drosophila* type of sex determination has been so frequently taken as a model in texts and reviews of all sorts that it is important to point out that in our case, and in the case reported by Jacobs and Strong[7], the *XXY* individual presented an essentially male phenotype, whereas in *Drosophila* the *XXY* fly is a fertile female[12]. If these cases should prove to be the first two instances of a general rule, it would indicate that the *Y*-chromosome in man is strongly 'male-determining', in contrast to the *Y*-chromosome of *D. melanogaster*, which is essentially inert in relation to the development of the sex phenotype, although necessary for male fertility[11].

We wish to acknowledge the skilful technical assistance of Mr. G. Breckon, Miss S. R. Wakefield and Miss P. A. Moore.

Addendum. Since the draft of this communication was completed, we have, in conjunction with our colleagues, Dr. D. G. Harnden and Dr. K. W. Jones, examined the chromosomes of three more chromatin-positive cases of Klinefelter's syndrome and of one chromatin-negative case of Turner's syndrome. The former all have 47 chromosomes, show no evidence of mosaicism and are presumptively *XXY* individuals. Forty-five chromosomes were found regularly in bone marrow cells from the patient with Turner's syndrome, and analysis of the detailed chromosome morphology is consistent with the anticipated *X*0 constitution. (Miss Jacobs and Dr. J. S. S. Stewart have kindly allowed us to state that they have found 45 chromosomes in a chromatin-negative case of Turner's syndrome, and that their observations are also consistent with *X*0 interpretation.)

TRANSPHOSPHORYLATING ENZYMES AND MUSCLE RELAXATION

By J. MOLNAR and DR. L. LORAND

Department of Chemistry, Northwestern University, Evanston, Illinois

THE pure creatine phosphate or the phosphoenolpyruvate kinase system greatly enhances the reversible relaxation of glycerinated rabbit muscle[1] (fibre bundles or single fibres) after contraction with adenosine triphosphate[2-5]. Transphosphorylation (presumably to adenosine diphosphate), though essential, is by itself insufficient to cause relaxation of old or specially extracted fibres. In such cases, in addition, the presence of a microsomal (or granular) fraction from muscle homogenate is required for relaxation. This has been demonstrated for the isotonic condition with creatine phosphate[6-8], and for isometric relaxation in conjunction with phosphoenolpyruvate[4,5].

Although the role of the microsomal principle for relaxation is generally accepted, the function of the transphosphorylating enzymes is regarded by many as 'unphysiological'[9-13]. It is claimed that the need for transphosphorylation arises only if the penetration by diffusion of adenosine triphosphate into the fibres cannot match the hydrolysis of the nucleotide by the myofibrillar adenosine triphosphatase. The addition of an enzyme system which restores adenosine triphosphate would merely ensure that the interior of the fibre maintains the necessary level of adenosine triphosphate similar to that prevailing in the bath in which the fibre is immersed. These contentions are based mainly on the work of Weber and his collaborators, and that of Bendall, who could not demonstrate any need for the addition of transphosphorylase in Marsh's system[14] in which, instead of fibres, homogenized myofibrils of microscopic dimensions are used. The experiment can be per-

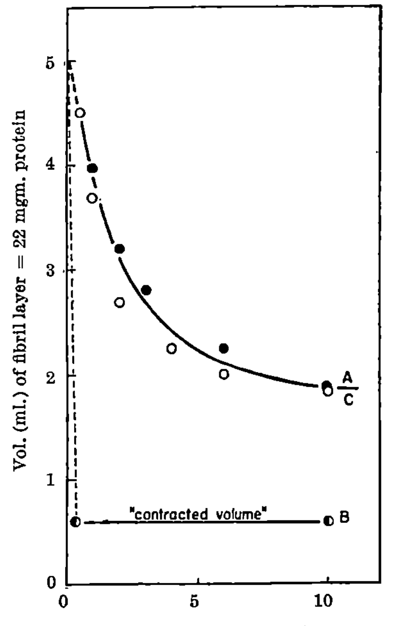

Fig. 1. Sedimentation of myofibrils. Magnesium chloride, 4 m*M*; *p*H about 6·5; $\mu \approx 0·15$; total vol., 5 ml.
A, fibrils (about 22 protein-mgm.—ref. 15) alone; *B*, fibrils + (1·04 protein-mgm. microsomes + 2·6 m*M* phosphoenolpyruvate—ref. 16) or (microsomes + 180 µgm. phosphoenolpyruvate kinase—ref. 17) + 4 m*M* adenosine triphosphate; *C*, fibrils + microsomes + phosphoenolpyruvate + phosphoenolpyruvate kinase + adenosine triphosphate

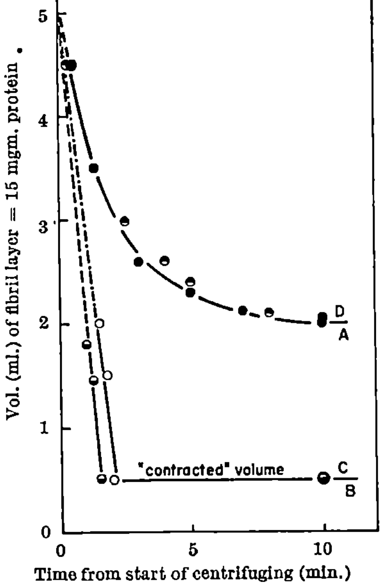

Fig. 2. Sedimentation of myofibrils. Conditions same as in Fig. 1. *A*, fibrils (about 15 protein-mgm.) alone; *B*, fibrils + 4 m*M* phosphocreatine (ref. 18) + 20 µgm. creatine phosphate transphosphorylase (ref. 19) + 4 m*M* adenosine triphosphate; *C*, fibrils + 1·52 protein-mgm. microsomes + adenosine triphosphate; *D*, fibrils + microsomes + phosphocreatine + creatine phosphate transphosphorylase + adenosine triphosphate

formed either by observing the packing volume of the myofibrillar layer during sedimentation in a low centrifugal field, or by measuring under the microscope the unloaded shortening of individual fibrils. The prevention of the mechanical change induced by adenosine triphosphate is generally assumed to be a phenomenon similar to relaxation.

In the present communication we wish to report that transphosphorylation is a very sensitive regulator of muscle 'relaxation' even in the Marsh experiment. This is noticeable particularly if the transphosphorylating enzyme systems are used in conjunction with such minimal amounts of microsomal component as would produce alone scarcely any effect. Figs. 1, 2 and 3 show this striking potentiation by the creatine phosphate and phosphoenolpyruvate kinase systems for inhibiting contraction. During centrifugation at about 1,000 r.p.m., at room temperature, the volume of the myofibrillar layer was measured with the aid of stroboscopic light. In Fig. 3 the results are presented in a somewhat more representative fashion. Fractional 'relaxation' (Q) is defined in terms of the volumes of myofibrillar layers as:

$$Q = \frac{V - V\,(\text{contracted})}{V\,(\text{standard}) - V\,(\text{contracted})} \times 100 \qquad (1)$$

where V represents an experimental volume at time t, V (standard) is the volume at time t of myofibrils sedimenting without the addition of adenosine triphosphate, and V (contracted) stands for the final volume of the myofibrillar pellet sedimented in the presence of adenosine triphosphate. It will be seen that values of Q less than 100 indicate contraction, and it can also be noted that both the creatine phosphate and phosphoenolpyruvate kinase systems prevent changes in volume very effectively under the experimental conditions described. Though not shown on the graphs, we have further demonstrated that the extent to which contraction is inhibited appears to be, within certain limits, a function of the concentration of phosphagens and their enzymes. Actually, by selecting appropriate conditions, Q values considerably greater than 100 can be obtained, which signify a swelling of the myofibrils.

Since lowering of the myofibrillar adenosine triphosphatase activity appears to be a characteristic symptom of the relaxed state in muscle (see, for example, ref. 13), we have studied the rate of hydrolysis of adenosine triphosphate by the myofibrils in the presence of various combinations of the microsomal component and transphosphorylating enzyme systems. Fig. 4 illustrates the finding that adenosine triphosphatase, though not suppressed by the concentrations employed of microsomes or transphosphorylase and phosphagen alone, is effectively reduced if they are all present simultaneously.

The myofibrillar material used in these experiments was obtained by homogenizing minced rabbit muscle with 0·15 M potassium chloride (buffered to about pH 6·8 with potassium salts of veronal and acetate) for 3 min. in the cold in a 'Virtis' homogenizer at 30,000 r.p.m. After centrifuging at 3,000 r.p.m., the light upper fibrillar layer was separated from the cell debris and was resuspended repeatedly (6–10 times) with the aid of the homogenizer and washed in buffered potassium chloride. In many instances, the fibrils were stored at − 20° C. in 50 per cent (v/v) glycerol and washed again in potassium chloride several times before use to eliminate the glycerol.

The microsomal component was isolated from the muscle homogenate as the fraction sedimenting between 11,000 and 54,000g, after the elimination of the inactive sediment obtained during centrifugation at 11,000g for 30 min. The microsomal fraction was resuspended in potassium chloride with

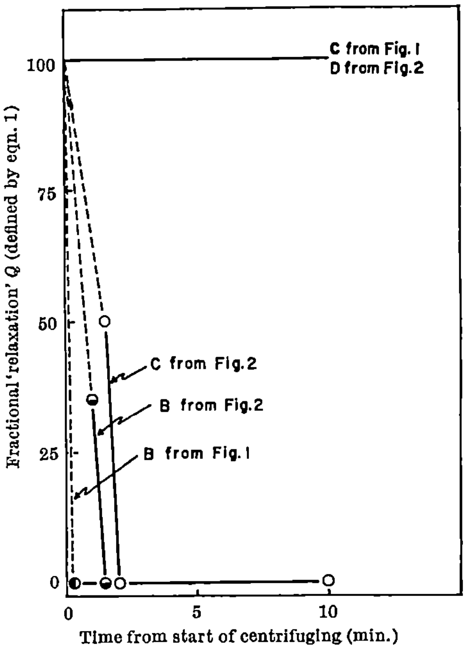

Fig. 3. Inhibition of the adenosine triphosphate-induced contraction of myofibrils by the creatine phosphate and phosphoenolpyruvate kinase systems. For explanation see text

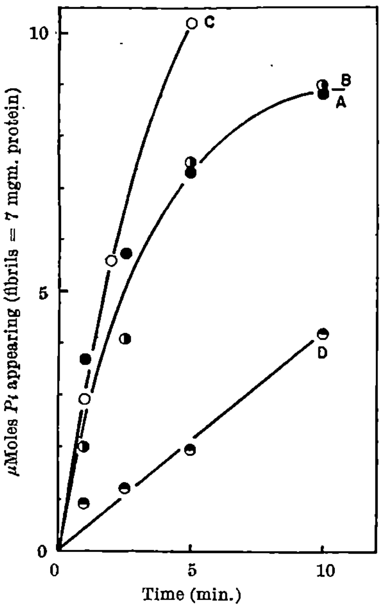

Fig. 4. Reduction of myofibrillar adenosine triphosphatase under the joint influence of microsomes and the phosphoenolpyruvate kinase system. Inorganic phosphate was measured by the method of Fiske and SubbaRow (ref. 20). Reaction mixture of 2·5 ml. at 25° C.: *p*H 6·5; $\mu \approx 0 \cdot 15$; 4 m*M* magnesium chloride; 4 m*M* adenosine triphosphate; about 7 protein-mgm. myofibrils. *A*, fibrils alone; *B*, fibrils + 1·19 protein-mgm. microsomes; *C*, fibrils + 0·35 protein-mgm. microsomes + 2·5 m*M* phosphoenolpyruvate + 150 μgm. phosphoenolpyruvate kinase; *D*, fibrils + 1·19 protein-mgm. microsomes + 2·5 m*M* phosphoenolpyruvate + 150 μgm. phosphoenolpyruvate kinase

the aid of a Potter hand-operated ground-glass homogenizer and centrifuged as before. This washing procedure was repeated several times.

In conclusion, the experiments presented here show that the interaction of the microsomal component of muscle with a transphosphorylating system is an essential feature of relaxation.

This work was aided by a grant from the Muscular Dystrophy Associations of America, Inc.

MECHANISM OF ACTION OF DIPHOSPHOPYRIDINE NUCLEOTIDASES

By PROF. SPYRIDON G. A. ALIVISATOS
Department of Biochemical Research, Mount Sinai Medical Research Foundation, Chicago Medical School

MAMMALIAN diphosphopyridine nucleotidases of the glycosidase type were first clearly described, as enzymes that inactivate coenzyme 1, by Mann and Quastel[1]. These workers demonstrated the inhibitory action of nicotinamide upon the reaction catalysed by diphosphopyridine nucleotidase. Later, Handler and Klein[2] showed that the enzymic breakdown of coenzyme 1 by tissue debris is accompanied by liberation of nicotinamide. The work of McIlwain *et al.*[3] established that this degradation of coenzyme 1 is accompanied by the conversion of a quaternary nitrogen structure to a trivalent one with the concomitant liberation of a hydrogen ion and of nicotinamide. They also showed that the reduced form of coenzyme 1 was not affected by the enzyme. These findings led to a formulation of the overall reaction as follows:

$$[\text{nicotinamide}^+\cdot\text{ribose-pyrophosphate-ribose-adenine}] + \text{HO}\cdot\text{H} \rightarrow \text{HO}\cdot\text{ribose-pyrophosphate-ribose-adenine} + \text{nicotinamide} + \text{H}^+ \quad (1)$$

where [nicotinamide$^+$·ribose-pyrophosphate-ribose-adenine] denotes coenzyme 1, and HO·ribose-pyrophosphate-ribose-adenine denotes the (ribose-pyrophosphate-ribose-adenine) derivative of coenzyme 1 after its nicotinamide moiety has been replaced by a hydroxyl-group.

Later, Zatman *et al.*[4] found that mammalian diphosphopyridine nucleotidase also catalyses an exchange reaction between free nicotinamide and the nicotinamide moiety of coenzyme 1. An explanation of this phenomenon was offered by Zatman *et al.*[4] by postulating a two-step reaction:

$$[\text{nicotinamide}^+\cdot\text{ribose-pyrophosphate-ribose-adenine}] + \text{enzyme} \rightleftharpoons [\text{enzyme}^+\cdot\text{ribose-pyrophosphate-ribose-adenine}] + \text{nicotinamide} \quad (2)$$

$$[\text{enzyme}^+\cdot\text{ribose-pyrophosphate-ribose-adenine}) + \text{HO}\cdot\text{H} \rightarrow \text{HO}\cdot\text{ribose-pyrophosphate-ribose-adenine} + \text{enzyme} + \text{H}^+ \quad (3)$$

Alivisatos *et al.*[5] found a diphosphopyridine nucleotidase in rabbit erythrocytes and described its distribution in these cells. They[6] also studied some of the requirements for the attachment of the substrate (coenzyme 1) on the enzyme. Later, Alivisatos and Woolley[7] solubilized and purified the diphosphopyridine nucleotidase from beef spleen, and, following a hypothesis of Woolley[8] on the utilization of the free energy of hydrolysis of 'onium' linkages, Alivisatos and Woolley[9] found that 5-amino-4-carboxamido-imidazole reacted with coenzyme 1 to form a new dinucleotide. In contrast to exchanges (for example, as in reaction 2), this imidazolytic[10] breakdown of coenzyme 1 was characterized by its irreversibility; the liberation of a hydrogen ion; and the presence of a trivalent nitrogen structure in the imidazole-ribose bond of the product[9]. The latter characteristic was most clearly demonstrated by the utilization of the new dinucleotide as a substrate in the enzymic formation of inosinic acid[10]. This demonstration established the identity of the imidazole-ribose bond in the dinucleotide with the imidazole-ribose bond present in the well-known precursor of purines, 5-amino-4-carboxamido-imidazole ribotide. Since the base-to-sugar configuration in coenzyme 1, in 5-amine-4-carboxamido-imidazole ribotide and in inosinic acid is the same (namely, β), the above-mentioned identity[10] implied a retention of configuration during the imidazolytic process and pointed towards a two-step reaction, each involving a Walden inversion[11]. The first step should be identical to the first step encountered in hydrolytic processes (reaction 2). This would also account for the inhibitory effect of nicotinamide upon the imidazolytic breakdown. The second step could be summarized in reaction (4), which should be taken as an alternative of reaction (3), if the imidazole is present in the medium:

[enzyme$^+$·ribose-pyrophosphate-ribose-adenine] + imidazole → enzyme + imidazole·ribose-pyrophosphate-ribose-adenine + H$^+$ (4)

where imidazole denotes the 5-amino-4-carboxamido-imidazole and other symbols have the same meaning as in reaction (1).

The finding[12] that another imidazole, namely, histamine, is even more capable of participating in reaction (4) focused new interest on the reactions catalysed by diphosphopyridine nucleotidase and called for a unified theory of action of this enzyme. (The "dinucleotide II" mentioned in a previous publication[12] proved later to be an artefact arising during the isolation procedures from "dinucleotide I". The imidazole-ribose bond of the latter has a trivalent nitrogen structure at *p*H 7·0, but it acquires a proton at lower *p*H values (*pK'* about 4·0).)

The above-mentioned observations, together with recent preliminary experimental evidence mentioned in a later part of the article, led to the formulation of the following hypothesis concerning the identity and the catalytic mechanism of the active group(s) of mammalian diphosphopyridine nucleotidases of the glycosidase type:

The two steps encountered in both the hydrolytic and imidazolytic processes (reactions (2), (3) and (4)) are virtually a succession of two nucleophilic attacks (each involving an inversion) upon carbon 1′ of the ribose moiety of coenzyme 1 close to nicotinamide. In the first (common) step the nucleophilic agent is a residue on the enzyme, while in the second step this part is played by water (hydrolysis) or an imidazole (imidazolysis).

While various groups of the diphosphopyridine nucleotidase may be important for its catalytic activity, our present evidence (see below) favours the participation of its histidyl-moieties. Of the possible forms of the amidine part of histidyl groups on the enzyme, the non-ionized form is expected to predominate over the *p*H range of activity of diphosphopyridine nucleotidases[6]. Certain contribution to the catalytic activity may possibly come from the anionic (deprotonated) form, especially at high *p*H values[13]. However, for clarity of discussion, only the non-ionized form is illustrated in Fig. 1 as participating in the catalysis. Thus, provided that the proper requirements for attachment of the substrate (coenzyme 1) on the enzyme surface are fulfilled[6], nicotinamide may be displaced from coenzyme I by a histidyl group of the enzyme (Fig. 1, *a*). The structures in brackets in Fig. 1 correspond to the [enzyme$^+$·ribose-pyrophosphate-ribose-adenine] intermediate encountered in reactions (2), (3) and (4).

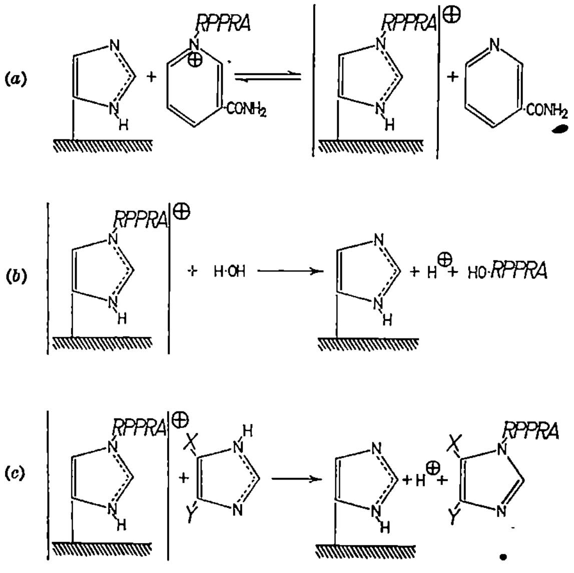

Fig. 1. Proposed scheme for the diphosphopyridine nucleotidase activities: *a*, exchange; *b*, hydrolysis; *c*, imidazolysis. The extreme (reactive) forms of histidyl groups of the free enzyme would be those of dipoles. *X* and *Y*, various radicals; RPPRA, ribose-pyrophosphate-ribose-adenine

In the absence of an excess of nicotinamide, other nucleophilic agents, for example, a hydroxyl or an imino-nitrogen of an imidazole, may react with the intermediate (Fig. 1, reactions *b* and *c*). The irreversibility of reactions *b* and *c* is due to the absence of an 'onium' structure in the products (HO·ribose-pyrophosphate-ribose-adenine and imidazole·ribose-pyrophosphate-ribose-adenine). An 'onium' structure like the one present in the oxidized form of coenzyme 1 (Fig. 1, reaction *a*) is necessary for the reversible exchange of the ·ribose-pyrophosphate-ribose-adenine radical with the enzyme. Thermodynamically, the necessity for a quaternary nitrogen structure reflects the higher free energy of hydrolysis of the nicotinamide-ribose bond, as compared with the free energy of hydrolysis of the imidazole-ribose bond[10].

A deeper understanding of the 'onium' structure requirement may be achieved by comparison with a simpler system, namely, the imidazole catalysis of hydrolysis of *p*-nitrophenyl-acetate[13,14]. In that case, a low electron density in the vicinity of the carbonyl-carbon atom (Fig. 2) is a major factor in determining the susceptibility of this carbon to a nucleophilic attack (for a discussion of other factors, see ref. 13). The nucleophilic agent is an imidazole, acting in a manner similar to the one postulated above for diphosphopyridine nucleotidase (Fig. 1). In the reaction catalysed by diphosphopyridine nucleotidase, on the other hand, the glycosidic carbon atom of a ribose moiety of coenzyme 1 is the target for the nucleophilic attack. This carbon is rendered to a certain extent electrophilic by the attached 'onium' structure (Fig. 2). While this polarization of the nicotinamide-ribose bond is apparently insufficient to make coenzyme 1 a suitable substrate for an

imidazole-catalysed hydrolysis[12], imidazolyl groups of the enzyme are probably capable of serving this purpose. A study of the influence of the various groups attached upon the carbon atom which serves as the electrophilic centre in substrates and intermediates (Fig. 2) involved in the hydrolytic processes catalysed by pyridine[11], imidazole[13,14] and the diphosphopyridine nucleotidase, will clarify this point better. Of the three substrates involved in these hydrolytic processes, namely, acetyl-phosphate, *p*-nitrophenyl-acetate and coenzyme 1 respectively, the latter is the most stable to spontaneous hydrolysis. This is due to the presence of a glycosidic structure, instead of a carbonyl, in the susceptible site of coenzyme 1. On the other hand, all three intermediates, namely, N-acetyl-pyridinium, N-acetyl-imidazole and the [enzyme$^+$·ribose - pyrophosphate-ribose-adenine], hydrolyse spontaneously after their formation. However, N-acetyl-pyridinium[11] has a much shorter life than N-acetyl-imidazole[14] in water. This is due to the presence of an 'onium' structure in the former intermediate[14]. The importance of an 'onium' structure in promoting the ability of such a bond to hydrolysis is further demonstrated by the well-known higher stability of the reduced form of coenzyme 1 to alkaline hydrolysis, as compared to its oxidized form (Fig. 2). The lability of the N(ring)-acetyl-histamine intermediate[13], as compared to the high stability of the imidazole-ribose bond in the histamine dinucleotide (Fig. 2), illustrates the importance of a carbonyl structure or other means tending to intensify the electrophilic character of the carbon atom at the site of the nucleophilic attack.

By analogy with the above examples, the extreme lability of the [enzyme$^+$·ribose-pyrophosphate-ribose-adenine] intermediate is probably due to a concerted action of an 'onium' structure and of other groups on the enzyme surface tending to increase the electrophilic character of the glycosidic carbon atom. The problem of the nature of the latter groups is left, at present, open.

The availability of soluble purified diphosphopyridine nucleotidase[7] prompted a more direct experimental approach to the problem of the identity of the active centre(s) of the enzyme. Although our evidence is as yet of a preliminary nature, it strongly favours the hypotheses put forward here. In each of these experiments 16 units of the enzyme (0·4 mgm. of protein) were treated, in a 5 per cent sodium bicarbonate medium (*p*H 8·0, 3·0 ml. total vol.), with the various reagents indicated in Table 1. When 2,4 : dinitrofluorobenzene was used, the reaction was carried in a heterogeneous system with 0·25 ml. of the reagent added. In this instance, the watery phase of both the experimental system and its control contained, in addition to bicarbonate, 5 per cent methanol. All other reagents were soluble, in the concentrations employed, in the bicarbonate medium. Proper controls (no reagent added) accompanied all experiments. The mixtures were shaken at a slow rate (prevention of frothing) at 4° C. for periods indicated in Table 1. At the end of the incubation, the samples were transferred in casings and dialysed, in separate containers, against 200 ml. of 5 per cent sodium bicarbonate, at 4° C. The apparatus allowed a continuous mixing of the contents of the casings as well as of the outside liquid in the containers. The latter was changed 4 times in a period of 48 hr. Hydrolytic diphosphopyridine nucleotidase activity was tested as previously[7].

As shown in Table 1, 2,4 : dinitrofluorobenzene completely abolished the enzymic activity of the sample. Photo-oxidation with methylene blue had the same effect. If —SH groups can be excluded on other grounds (see below), this effect of methylene blue is regarded as rather specific for the histidyl residues of a protein[15]. Fluorescein *iso*thiocyanate reacts primarily with free aliphatic amino-groups (for example, lysine). However, we found that it also reacts with imidazoles (for example, acetyl histamine). In accordance, it had an effect on the diphosphopyridine nucleotidase activity (Table 1). Azo-enzyme, prepared by reaction with 3·75 µmoles of diazotized sulphanilic acid, was completely inactive. However, a ten times smaller amount of the reagent resulted in only partial inactivation. These results indicate reaction first with tyrosyl residues and, afterwards, with histidyl groups of the protein. However, anomalies in the interaction of diazo-

Table 1. EFFECT OF VARIOUS REAGENTS UPON THE ACTIVITY OF DIPHOSPHOPYRIDINE NUCLEOTIDASE

Reagent	Total amount of reagent (µmol.)	Duration of reaction (hr.)	Per cent loss of hydrolytic activity

10. Iodoacetate	5·000	16	0
11. *p*-Chloromercuribenzoate	0·320	6	0
12. *p*-Chloromercuribenzoate	6·500	6	0

reagents with proteins should be kept in mind[16]. The effect of iodine (Table 1) may be interpreted in a similar manner. Iodoacetate and *p*-chloromercuribenzoate did not have any appreciable effect on the activity of diphosphopyridine nucleotidase. The exclusion of —SH groups as possible participants in the enzymic activity was rather unexpected, in view of results by Stadtman *et al.*[17]. These workers discovered an enzyme that catalyses a reaction between acetyl-S-coenzyme *A* and imidazole to form the N-acetyl derivative.

Histidyl residues have been regarded as essential to the activity of several hydrolytic enzymes (see refs. in 13 and 14). According to our experimental findings, this seems to be also true for the diphosphopyridine nucleotidase. Considering the diverse catalytic capacities of this enzyme (namely, exchanges, hydrolytic and imidazolytic processes), that essentially parallel the various model systems developed for the study of the mechanism of enzymic hydrolysis, diphosphopyridine nucleotidase may prove very useful for such studies.

This project was partially supported by a U.S. National Institutes of Health grant No. *E*-2436. I wish to thank Drs. I. Davidsohn and K. Stern of the Mount Sinai Medical Research Foundation for their interest in this work.

MOLECULAR ADAPTATION IN HÆMOGLOBINS: NATURE OF THE BOHR EFFECT

By AUSTEN RIGGS

Department of Zoology, University of Texas, Austin

SCHMIDT-NIELSEN[1] has shown that among terrestrial mammals the smaller the animal the higher is the oxygen pressure (P_{50}) at which the whole blood is half-saturated with oxygen. Thus the blood is adapted to deliver oxygen to the tissues at higher pressures in the smaller animals the specific rates of oxygen consumption of which are highest.

Recently, I have found[2] that the primary difference between these bloods lies in the sensitivity of their hæmoglobins to changes in *p*H. As the 'Bohr effect', it is well known that high carbon dioxide pressure or decreased *p*H tends to dissociate oxyhæmoglobin, and so promotes gas exchange in the tissues. In a series of terrestrial mammals, ranging in size from elephant to mouse, the smaller the animal the greater is the sensitivity of the oxygen equilibrium of its hæmoglobin to *p*H. This *p*H sensitivity (Bohr effect) reflects the fact that certain acid groups of the hæmoglobin are functionally linked to the oxygenation process in such a way that they become more acidic when oxygen is bound[3,4]. Therefore, the results indicate that the smaller the mammal the greater is the number of protons discharged from its hæmoglobin when the molecule is oxygenated. This effect not only promotes gas exchange but also is a homœostatic buffering mechanism.

I have now determined the number of mercuric ions which can be immediately bound to these hæmoglobins, using the amperometric procedure of Kolthoff, Stricks and Morren[5]. The hæmoglobin solutions were prepared as previously described[6]. The titrations were performed at 25° C. in an atmosphere of helium; thus reduced hæmoglobin was titrated. These titrations indicate a linear relation between the magnitude of the Bohr effect, defined as $\Delta \log P_{50}/\Delta p\mathrm{H}$, and the number of mercuric ions bound per molecule of hæmoglobin. This is shown in Fig. 1. Only the rabbit appears really exceptional.

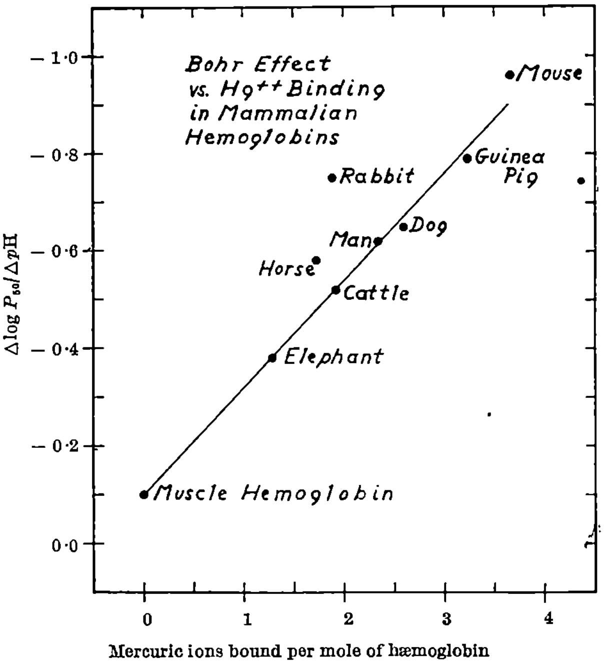

Fig. 1. The relation between the magnitude of the Bohr effect and the number of mercuric ions which can be bound per hæmoglobin molecule. The data for muscle hæmoglobin are from Theorell (ref. 8)

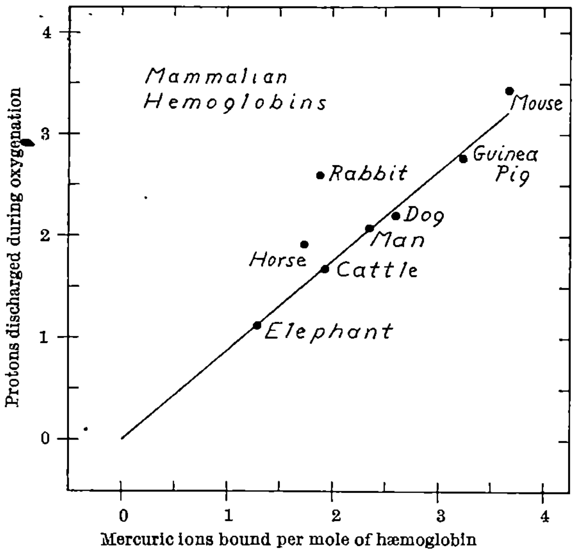

Fig. 2. The relation between the number of protons discharged by hæmoglobin during its oxygenation as calculated in the text, and the number of mercuric ions which may be bound per molecule

Thus the magnitude of the Bohr effect appears to be directly proportional to the number of sulphydryl groups.

The conclusion that the oxygen-linked acid groups are sulphydryl groups is strengthened by the following considerations. Horse-muscle hæmoglobin has no sulphydryl groups[7]; the value of its Bohr effect[8] is approximately 0·1. Extrapolation of the line in Fig. 1 to the point at which zero mercuric ions are bound corresponds to just this value. If we assume that the small non-sulphydryl Bohr effect exhibited by muscle hæmoglobin is also present in all the blood hæmoglobins, then we can subtract the Bohr effect value in muscle hæmoglobin from all the other values to obtain the Bohr effect due solely to sulphydryl groups. Wyman has shown that $\Delta\log P_{50}/\Delta p\mathrm{H}$ is directly proportional to the number of protons discharged during oxygenation[4]. Therefore we should be able to calculate the number of sulphydryl protons dissociated during oxygenation. In Fig. 2 the number of protons so calculated is plotted against the number of mercuric ions bound. It is clear that a rather good one-to-one quantitative correspondence exists. The number of mercuric ions bound is only 10 per cent higher than the number of protons dissociated. If the oxygen-linked acid groups are sulphydryl groups, the binding of these groups with an irreversible reagent such as N-ethyl maleimide should result in greatly reducing the magnitude of the Bohr effect. We find that low concentrations (5 moles N-ethyl maleimide per mole of hæmoglobin) have just this effect: not only is the oxygen affinity increased but also the magnitude of the Bohr effect decreases greatly: $\Delta\log P_{50}/\Delta p\mathrm{H}$ drops from 0·65 to 0·28 in human hæmoglobin at 35° C.

These observations led us to predict that whenever we find hæmoglobins the oxygen equilibria of which are insensitive to *p*H (no Bohr effect), we might expect to find either no, or a very small number of, sulphydryl groups. I had previously found that tadpole hæmoglobin has no Bohr effect whereas that of the adult bullfrog has a large Bohr effect[5]. I have re-examined tadpole hæmoglobin, and find that it binds the smallest number of mercuric ions of any blood hæmoglobin so far examined: only 0·8 mercuric ion per mole of hæmoglobin. In contrast, the adult bullfrog hæmoglobin molecule binds about 4·2 mercuric ions.

It is well known that the four hæm groups present in each hæmoglobin molecule interact with one another. That is, oxygenation of certain of these hæms greatly enhances the affinity of other hæms for oxygen. I have shown previously that sulphydryl reagents can abolish this interaction[6–10]. It now appears that the interaction is destroyed when mercurials are bound to the oxygen-linked acid groups which are now identified as sulphydryl groups. Thus two properties of hæmoglobin of great physiological importance, the S-shape of the oxygen equilibrium curve and the dependence of the equilibrium on *p*H, are both mediated by sulphydryl groups.

The suggestion that the oxygen-linked acid groups are imidazole residues was based on the correspondence between the observed *pK* values and heats of dissociation and those of imidazole[4], and on the changes anticipated in the electronic structure of imidazole resulting from covalent linkage with the hæm iron[11]. Unfortunately, both the *pK* values and the heats of dissociation are often very similar in both —SH groups and imidazole[12,13]. Although mercurials do have affinity for imidazole groups, the affinity for —SH groups is generally much higher. Furthermore, in human hæmoglobin at least, a one-to-one correspondence exists between the number of N-ethyl maleimide molecules bound, and the number of cysteine residues found analytically[14]. In our experiments the number of mercuric ions that can be immediately bound by human hæmoglobin drops by two-thirds within 5 min. after the addition of five moles of N-ethyl-maleimide per mole of hæmoglobin; the mercury titration is zero after 15 min. The effect of N-ethyl-maleimide on the oxygen equilibrium is very similar to that of the mercurial, mersalyl.

These observations suggest that one of the primary physiological adaptations of hæmoglobins is brought about by varying the number of cysteine residues per molecule. If it is physiologically advantageous for an animal to possess a hæmoglobin with a large Bohr effect, mutants with hæmoglobins possessing a larger number of appropriately placed cysteine residues would be selected. This conclusion is supported by the amino-acid analyses of Birkofer and Taurins[15], who examined the hæmoglobins of 7 species of mammal. Their results clearly indicate an inverse relation between body-weight and number of cysteine residues in each hæmoglobin.

A full report of these experiments will be published elsewhere. I wish to acknowledge the assistance of Messrs. Patrick Barlow and Allen Tyler. The research was supported in part by a grant from the National Science Foundation.

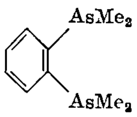
CHEMISTRY

New Oxidation States of Technetium

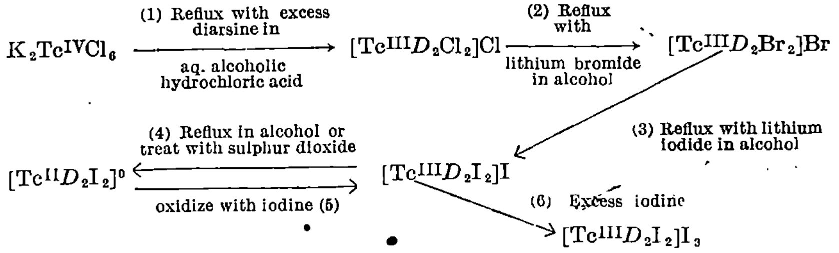
THE chemistry of technetium, the middle member of the Group VII triad with manganese and rhenium as its congeners, has been little investigated until recently owing to its rarity. Indeed, since the isolation of the isotope technetium-99 in gram quantities from the products of uranium fission[1] the oxidation states +7 and +4 only have been definitely established for this element, at least in solid compounds. These are exemplified by $KTcO_4$ and Tc_2S_7 in the first case and TcO_2, TcS_2, $TcCl_4$ and K_2TcHal_6 (Hal = Cl, Br and I) in the second[1]. Evidence[2] for the existence of green tervalent technetium in solution has been adduced from the reducing power of an electrolytically produced aqueous solution, but no compound of technetium III was isolated. Similarly, technetium V probably exists in solution as the complex thiocyanate, but no solid compound has been isolated[3]. The close similarity of rhenium and technetium suggested that for the preparation of lower oxidation states of technetium a study of the corresponding rhenium chemistry would be very helpful.



Ditertiary arsine (*D*)

Recent work[4] has shown that very stable bivalent and tervalent rhenium compounds may be prepared by using the ditertiary arsine (*D*) as a chelating ligand. These have the general formula $[Re^{II}D_2X_2]^0$ and $[Re^{III}D_2X_2]ClO_4$, where X = Cl, Br or I. The bivalent complexes are non-electrolytes, paramagnetic, ($\mu \approx 1{\cdot}8$–$1{\cdot}9$ Bohr magnetons) and are clearly octahedral, spin-paired d_ε^5 compounds. The tervalent derivatives are uni-univalent electrolytes in nitromethane and clearly involve octahedrally co-ordinated rhenium III with a d_ε^4 configuration. The magnetic moments ($\approx 1{\cdot}9$ Bohr magnetons) are less than the spin-only value for two unpaired electrons (2·83 Bohr magnetons), but these are readily understood in terms of the Kotani[5] theory for octahedral strong-field complexes of elements with a large spin-orbit coupling constant.

Following the procedure used to obtain the above rhenium compounds, we have now been able to prepare the corresponding technetium II and technetium III derivatives. Starting from potassium hexachlorotechnetate[6], the sequence of reactions employed is as follows :



K₂TcIVCl₆
(1) Reflux with excess diarsine in
aq. alcoholic hydrochloric acid
[TcIIID₂Cl₂]Cl
(2) Reflux with
lithium bromide in alcohol
[TcIIID₂Br₂]Br
(3) Reflux with lithium iodide in alcohol
[TcIIID₂I₂]I
(4) Reflux in alcohol or treat with sulphur dioxide
[TcIID₂I₂]⁰
oxidize with iodine (5)
(6) Excess iodine
[TcIIID₂I₂]I₃

Having only 15 mgm. of technetium, the usual analytical procedures are not feasible, but reactions 2 and 3 have been confirmed quantitatively by measuring both the amount of the less electronegative halide entering the complex and the amount of more electronegative halide which is displaced. Reaction 5 has been shown to proceed with the uptake of exactly one equivalent of iodine. Conductivity, molecular weight and magnetic data have been obtained on these compounds and, taken in conjunction with the known properties of the corresponding Re II and III derivatives, provide further confirmation of the composition and structure of the new complexes. Finally, it has been shown by X-ray powder photographs that the rhenium II and technetium II compounds are isomorphous. The properties of these compounds are summarized in Table 1.

* Λ_M for a uni-univalent electrolyte in nitromethane at 10^{-3} *M* is 70–90 ohm^{-1}.

† Molecular weight. Found 435, isopiestic in acetone. Calculated for 1 – 1 electrolyte 455.

‡ From X-ray powder photographs the $[TcD_2I_2]^0$ is isomorphous with $[ReD_2I_2]^0$, and $[TcD_2I_2]I_3$ with $[ReD_2I_2]I_3$.

The tervalent technetium compounds are similar to those of tervalent rhenium, except that the magnetic moments are higher, as expected. They differ very much from the known[7] diarsine complexes of manganese III, which are spin-free and have the general formula $[MnDX_2.H_2O]ClO_4$, where X = Cl or Br.

Bivalent technetium resembles both manganese II and rhenium II in forming compounds of the type $[Tc^{II}D_2I_2]^0$, but the magnetic moment of this compound is unusual, agreeing neither with the spin-free value for five unpaired electrons as in $[MnD_2I_2]^0$, nor with the spin-paired value for one unpaired electron as in $[ReD_2I_2]^0$. The position of technetium in the periodic table provides a clue to this behaviour which will be discussed in a more detailed report on these compounds to be published shortly.

We are grateful to the United Kingdom Atomic Energy Authority for the loan of the technetium used in this work. One of us (J. E. F.) also thanks the University of New Zealand for a postgraduate scholarship.

Cyclic Alternating-Current Voltammetry with a Platinum Electrode

The a.c. polarographic method of Brewer and Gutmann[1], in which a.c. instead of d.c. current is measured against polarization potential, has hitherto not been extended to the determination of compounds reducible or oxidizable at potentials more positive than the potential of dissolution of mercury. This limitation is due to the difficulty of reproducing a.c. current-voltage curves obtained with solid electrodes. Changes in the nature of the surface of the electrode are responsible for poor reproducibility in conventional voltammetry[2]; even worse results can be expected in a.c. voltammetry because changes in the nature of the electrode modify the impedance much more than the resistance of the double layer during the electrolytic process.

One can expect an electrode to acquire different reproducible states of accommodation during the electrolytic processes when submitted to a series of cyclic polarizations in a solution to be investigated. Kemula and Kublick[3] (and Kemula, K., personal communication) have already shown that perfectly repeatable d.c. polarograms are obtained when a hanging-drop mercury electrode is polarized cyclicly at a moderate rate between 0·2 and − 2·0 V. versus a standard calomel electrode. In fact, reproducible a.c. polarograms are also recorded with a platinum electrode when the electrode is polarized cyclicly at approximately 2·5 V./min. between − 1·0 and 1·5 V. versus a standard calomel electrode in a solution through which nitrogen is bubbling.

Besides their perfect repeatability, cyclic a.c. polarograms obtained with a platinum electrode have two important properties: (1) with alternating current most of the characteristic peaks appear only on the portion of the polarogram scanned from negative to positive, the portion of the cycle scanned in the opposite direction to that normally used; (2) the position and the height of the characteristic peaks are practically unaffected by the mechanical stirring of the solution.

As an example, Fig. 1 shows two recorded cyclic polarograms (curves 1 and 2) of 0·1 *M* sodium perchlorate solutions containing $2 \cdot 5 \times 10^{-6}$ *M* and 5×10^{-4} *M*, respectively, of potassium iodide, together with their d.c. polarograms (curves 1′ and 2′). These polarograms were obtained with a 3 $mm.^2$ platinum/10 per cent rhodium wire working electrode and a 25 $cm.^2$ saturated calomel auxiliary electrode. The a.c. polarograms were obtained by feeding the cell with a 60 c./s., 0·03 root mean square sinusoidal voltage, in parallel with the linearly scanned d.c. voltage. The a.c. and d.c. currents were restricted from other circuits by a low-resistance 10-henry inductor and by a capacitor of a few microfarads placed in the d.c. and a.c. circuits, respectively. The relative admittance of the cell is determined by the voltage drop across a resistor located in the a.c. circuit. This voltage was measured in these experiments with an electronic a.c. millivoltmeter, and was recorded through a self-balancing millivolt potentiometer.

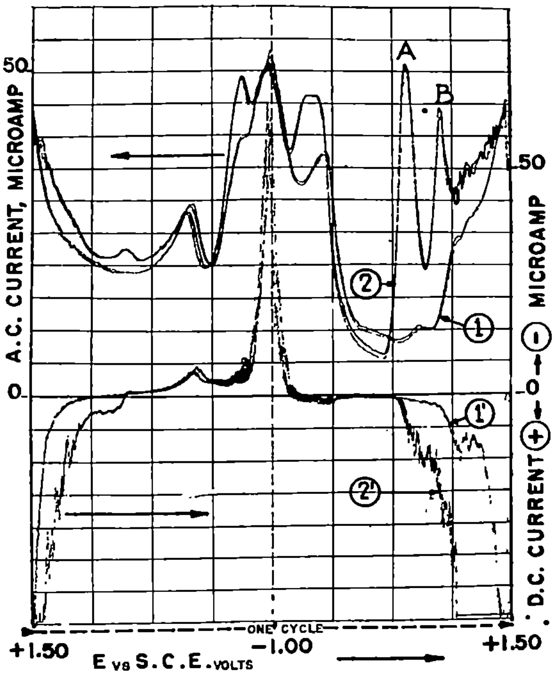

Fig. 1. Cyclic a.c. (curves 1 and 2) and d.c. (curves 1′ and 2′) polarograms of 0·1 *M* sodium perchlorate solution containing potassium iodide: (*a*) $2 \cdot 5 \times 10^{-6}$ *M* (curves 1 and 1′); (*b*) $5 \cdot 0 \times 10^{-4}$ *M* (curves 2 and 2′)

The addition of 0·5 m*M* potassium iodide to the 0·1 *M* sodium perchlorate solution (curves 2 and 2′) markedly affected the shape of the second half-cycle of the a.c. polarogram, while the shape of the part scanned from positive to negative of the curve remained practically unchanged. The repeatability of the curve is so good that there is scarcely any difference between the duplicated curves recorded in Fig. 1 despite the complicated pattern of the curve. No clear relation appeared between the admittance peaks *A* and *B* of the 0·5 m*M* potassium iodide solution and the cyclic d.c. polarogram of the same solution (curve 2′). The diffusion current of the d.c. polarogram showed irregular fluctuations due to the nitrogen bubbling. No such fluctuations appear on the a.c. polarogram.

The height of peaks *A* and *B* increases with the concentration of iodide, and seems to be determined by the rate of oxidation of iodide ions adsorbed on the electrode. The height of peak *B*, which increases with the addition of iodine and decreases with the addition of starch or thiosulphate, seems to be related to the rate of oxidation of adsorbed iodine, probably to I^+. The amount of iodide and iodine contained in the solution can be determined by the height of the peaks *A* and *B* after establishment of a calibration curve.

Perfectly repeatable cyclic a.c. polarograms are also obtained when compounds like ferricyanide or hydroquinone, which are reversibly or semi-reversibly reducible or oxidizable between the potential of evolution of hydrogen and oxygen, are added to a sodium perchlorate solution. Repeatable polarograms are obtained even with species like Ag^+ and Pb^{2+}, which form a deposit on the surface of the electrode, when the solution is made acid with perchloric acid. In this case the results are repeatable so long as the amount of product reduced during the first half-cycle is still completely re-oxidized during the next one. The peak maximum obtained with deposited metal coincides quite well with the moment at which the last trace of the reduced product disappears at the surface of the electrode.

Cyclic a.c. voltammetry with a platinum electrode can therefore be used as a convenient method for the analysis of compounds reversibly or semi-reversibly reducible or oxidizable at potentials between $-1{\cdot}0$ and $+1{\cdot}5$ V. versus a standard calomel electrode. It also appears to be an excellent method for studying the mechanism of electrolytic processes at a solid electrode.

Polymorphic Conversion of Mercuric Iodide on Alumina

It is well known that mercuric iodide exists in two crystalline forms, the stable red form being converted to the metastable yellow at 127° C.[1]. Recently, Sieskind[2] has reported an orange modification which was isolated from both ethyl acetate and acetone.

The information available concerning the spectral characteristics of mercuric iodide in solution is apparently limited to a paper by Gewenlock and Trotman[3], who have reported that the transmission spectrum of red mercuric iodide in ethanol has two broad absorption bands in the ultra-violet, with maxima at approximately 215 and 273 mμ. No mention is made of any characterizing absorption in the visible region. There are no comparable results regarding the metastable yellow form which quickly reverts to the red form upon standing or treatment with solvents.

Work by Zeitlin and Niimoto[4] showing that characteristic reflexion spectra of solids could be obtained on active adsorbents provided a method for the measurement of the spectra of both the red and the yellow forms in the solid state.

A small quantity (50 mgm.) of powdered red mercuric iodide of analytical grade was mixed with 2·5 gm. of active chromatographic alumina (>140 mesh) Woelm—activity grade 1. Within a short time it became evident that a conversion from the red to the yellow form was occurring. The change from a heterogeneously dispersed mixture of red mercuric iodide and alumina to one which was decidedly yellow and homogeneous in appearance was striking and practically complete in a few days at room temperature. The transition proceeded at 0° C. but at a much slower rate. It was substantially accelerated by mild heating. Although the yellow form is unstable when prepared in the usual manner, it apparently can be stabilized and maintained indefinitely on alumina in a moisture-free atmosphere. Exposure to the atmosphere or addition of water to the yellow form on alumina resulted in reversion to the red form. When the yellow form on alumina was extracted with ethanol or ether, the red modification was obtained.

The reflexion spectra of the solid mixtures were obtained with a Beckman *DU* spectrophotometer equipped with a standard reflectance attachment. Fig. 1, curves *a*, *b*, *c*, gives the spectra on alumina of the red, mixture of the red-yellow, and the yellow forms. The spectra, which are reproducible, differ in several details from the transmission spectra in ethanol. In reflectance, the first broad band is resolved into two smaller ones while the second maximum is retained. There is a definite bathochromic displacement of the optical peaks in going from transmittance to reflectance. In addition, there is a shoulder in the reflexion spectrum of the red form in the visible region which has not been reported in the transmission spectrum. In order to detect the spectral differences between the two forms, the spectra of the mixtures of mercuric iodide and alumina were taken immediately after mixing, after a few hours to permit partial conversion to the yellow modification, and after several days when the conversion to yellow mercuric iodide was complete. This enabled direct comparison of the spectra of the mixtures with identical quantities of mercuric iodide. The results show (Fig. 1, curves *a*, *b*, *c*), with increasing concentration of the yellow relative to the red form, a corresponding decrease in the absorbance in the shoulder region (about 560 mμ). The red form possesses in reflectance a shoulder in the visible that is absent in the yellow modification. It has been impossible to obtain the spectrum of the pure red form on alumina due to the change that takes place immediately after mixing. Consequently, red mercuric

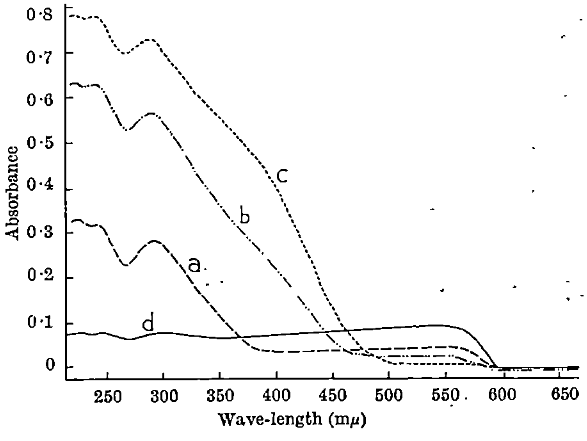

Fig. 1. Comparison of the reflexion spectra of polymorphic forms of mercuric iodide: *a*, red mercuric iodide on alumina; *b*, red-yellow mercuric iodide on alumina; *c*, yellow mercuric iodide on alumina; *d*, red mercuric iodide on sodium fluoride

iodide was mixed with powdered inactive sodium fluoride and the reflexion spectrum measured. The spectrum of pure red mercuric iodide (Fig. 1, curve *d*) so obtained is similar to the spectrum of the red form on alumina in all important details. The reflexion spectra of mercuric iodide on alumina are therefore not modified significantly by the active adsorbent.

Energy required for the conversion of the stable to the metastable form is apparently derived from the heat liberated by the adsorption of mercuric iodide on alumina. Our experimental findings are in agreement with the theory advanced by Tovbin and Baram[5] concerning the catalytic conversion of a stable to a less-stable form through heat of adsorption.

Solution of Iodine in Phosphorus(III) *Isocyanate*

DURING an investigation of the solvent properties of phosphorus(III) *iso*cyanate[1] it was observed that iodine dissolved to give a reddish-brown solution. It is well known that such coloured solutions of iodine in 'active' solvents indicate some sort of solvent-solute interaction[2].

Previously[3], it had been noted that iodine dissolved in phosphorus trichloride to give a violet solution with an absorption maximum at 5000–5200 A. Since —NCO can be looked upon as a pseudo-halide, it might be expected that phosphorus *iso*cyanate and phosphorus trichloride would behave similarly in so far as reaction with iodine is concerned.

Iodine dissolves slowly in phosphorus *iso*cyanate with little heat of solution. The resulting solution is red-brown and shows an absorption maximum at 3300 A. If an excess of iodine is added to phosphorus *iso*cyanate a solid results. Removal of unreacted iodine with carbon tetrachloride yields an orange powder containing one half mole of iodine per mole of phosphorus *iso*cyanate. This adduct reacts violently with water, a property commonly associated with the species phosphorus(III). In contrast, chlorine reacts vigorously with phosphorus *iso*cyanate, sufficient heat being generated to boil the solution. The resulting yellow oil solidifies on contact with carbon tetrachloride to give a yellow crystalline solid, presumably $P(NCO)_3Cl_2$. The latter shows no evidence of phosphorus(III) formation after hydrolysis in water, thus indicating pentavalent phosphorus with chlorine bonded to phosphorus.

The colour of the solutions of iodine in phosphorus trichloride and in phosphorus *iso*cyanate may be a result of the inability of iodine to co-ordinate to phosphorus in the former (due to the electron-withdrawing power of chlorine) and the enhanced co-ordination in the latter (due to the electron donation of *iso*cyanate). Steric effects may also be involved in the case of iodine and phosphorus trichloride since no PCl_3I_2 has been confirmed, although such a compound has been reported[4].

The adducts $P(NCO_3)I$, as observed in this work, and PCl_3I [4] are similar in stoichiometry and would seem worthy of further investigation.

We wish to thank the Research Corporation of New York for financial support of part of this work.

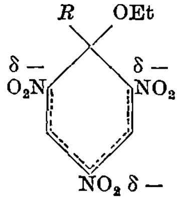
Interaction of 1,3,5-Trinitrobenzene with Ethoxide Ion

WHEN a dilute solution of 1,3,5-trinitrobenzene in ethanol is treated with sodium ethoxide, a yellow solution is formed. A similar colour is produced when sodium ethoxide is added to 2,4,6-trinitroanisole. The rates of development of the colours have been studied by Ainscough and Caldin[1], who found that there are two colour-producing reactions : (i) a 'fast' reaction the product of which they suggest is a charge-transfer complex, and (ii) a 'slow' reaction, which probably produces an addition compound where OEt is covalently bonded to the nucleus, as was suggested by Meisenheimer[2] for the solid obtained in this reaction (I, R = OCH_3). With 1,3,5,-trinitrobenzene and sodium ethoxide only one reaction was observed, and on the basis of similar rates of reaction and similar effects of acid on the two systems, Ainscough and Caldin suggested that the product is a charge-transfer complex analogous to the 'fast' reaction with 2,4,6-trinitroanisole. The absorption spectra of the trinitrobenzene + sodium ethoxide obtained by them did not resemble that of trinitroanisole + sodium ethoxide.



(I)

The absorption spectrum of 2,4,6-trinitroanisole in ethanol in the visible region in the presence of an excess of potassium ethoxide has been re-measured and compared with that of 1,3,5-trinitrobenzene under the same conditions. If measured within an hour of mixing at room temperature, the two spectra, expressed in terms of the formal molar extinction coefficient (optical density/molarity of nitrocompound) do resemble one another closely. Both solutions obey Beer's law and both bear a close resemblance to Meisenheimer's compound in acetone[3]. After a day, the spectrum of 1,3,5-trinitrobenzene in excess potassium ethoxide resembles that obtained by Ainscough and Caldin. Similar results were obtained using sodium ethoxide. This suggests that 1,3,5-tri-

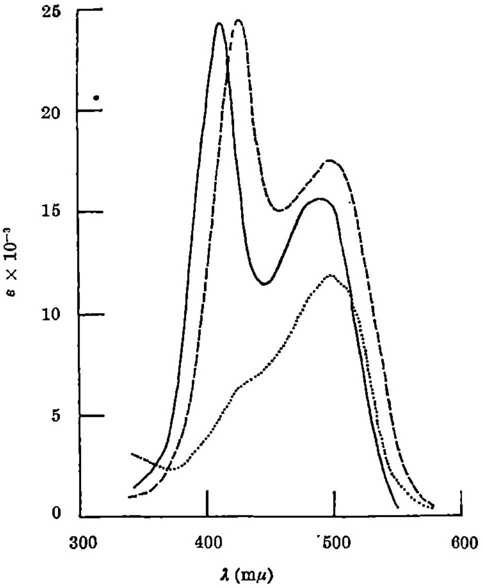


Fig. 1. ——, Potassium ethyl 1-methoxypicrate ($2{\cdot}27 \times 10^{-5}$ *M*) and potassium ethoxide ($6{\cdot}8 \times 10^{-2}$ *M*); – – – –, 1,3,5-trinitrobenzene ($3{\cdot}23 \times 10^{-5}$ *M*) and potassium ethoxide ($6{\cdot}8 \times 10^{-2}$ *M*) within 30 min. of mixing; . . . . , the same after 24 hr. All solutions in ethanol at 20° C.

nitrobenzene + ethoxide initially gives an addition product (I, R = H) which corresponds with the Meisenheimer compound.

The spectra were measured on an Optica *CF*4 grating spectrophotometer.

This work was carried out during the tenure of an Edward A. Deeds Fellowship of the University of St. Andrews.

Relation between the Polarizability of Ions and other Significant Properties

In a previous communication[1] it was reported that the polarizability α of an ion is proportional to N^2 (N being the atomic number of the element). In order to examine the extent to which this relation, $\alpha = kN^2$, where k is a constant, is applicable in the case of ions, the data for the polarizabilities of ions[2] were plotted against the values of N^2 for the corresponding ions. It was found that it is applicable for elements in the same sub-group of the periodic table, although the proportionality constant k in this relation for earlier members of each sub-group differs from that applicable to the higher members of the same sub-group.

By applying this criterion, the element fluorine is found to differ from the other halogens, chlorine, bromine and iodine, in having a lower polarizability than that to be expected from the above formula. Similarly, lithium and sodium ions differ from potassium, rubidium and cæsium ions in group 1*A*, beryllium and magnesium differ from calcium, strontium, and barium ions, and so on. Such differences in the behaviour of the earlier elements in the sub-groups from those occurring higher up are in agreement with the corresponding differences in the chemical behaviour between fluorine on one hand and chlorine, bromine and iodine on the other, lithium and sodium from potassium, rubidium and cæsium and so on. This is evidently to be attributed to the electronic configurations in the atoms.

It is found also that for elements belonging to the same series in the different periods, the values of α decrease with increase in N^2.

Another interesting correlation has been obtained by plotting the values of the electric polarizabilities of ions against their magnetic susceptibilities, χ (see ref. 2). The graph thus obtained shows a distinct proportionality between the two, the relation being $\alpha = K_0\,\chi$, where K_0, the constant of proportionality, is different for positive and negative ions.

PHYSICS

Nuclear Magnetic Resonance in Rolled Copper Sheet

An investigation has been made of the copper-63 nuclear magnetic resonance in rolled copper sheet. The specimens were made from an electrolytic copper of commercial purity and consisted of a pile of 18 sheets each measuring 0·6 cm. × 0·5 cm. × 0·0045 cm. and insulated from each other by rice paper of thickness 0·003 cm. The measurements were made with a Colpitts marginal oscillator at a frequency of 5·5 Mc./s., using a permanent magnet with pole pieces of 4·5 in. diameter and 1·5 in. gap.

The following features were observed.

(1) In sheet which has been recrystallized after heavy deformation by rolling (90 per cent reduction in thickness or more) the width of the line varies with the orientation of the specimen relative to the main magnetic field. This effect occurs for all annealing temperatures investigated (240–600° C.) but is more pronounced for the higher temperatures. If the specimen is rotated about the transverse direction (the direction in the plane of the sheet perpendicular to the rolling direction) the line-width shows minima for $\theta = 0$ and $\theta = \pi/2$, and a maximum for $\theta = \pi/4$, where θ is the angle between the main magnetic field and the plane of the sheet. The magnitude of the variation may be as much as ± 15 per cent in the mean square line-width.

This effect can be explained by the Van Vleck theory of dipolar broadening[1] if it is assumed that there is present in the specimen a preferred orientation of the type usually observed in recrystallized rolled sheet[2].

A variation of line-width with θ is also found for the deformed sheet; this is of a different nature from that in the annealed sheet, and is more difficult to interpret in terms of the expected preferred orientations.

(2) Annealing of a deformed specimen produces no detectable change in the shape of the resonance line, nor in its width except in the case of the most heavily deformed specimens (90 per cent reduction in thick-

ness). With these last specimens at all values of θ, except those near $\theta = \pi/4$, there is a narrowing of the line on annealing which is ascribed to a change in the preferred orientation; for $\theta = \pi/4$ there is no measurable change in the width. However, annealing causes an increase in the intensity of the line by about 25 per cent above that of the deformed sheet, and this increase appears to be independent of the degree of deformation in the range 25 per cent to 90 per cent reduction in thickness by rolling.

(3) For specimens of deformed sheet given a succession of heat treatments at temperatures increasing in steps of 10° C., the increase in intensity of the line is found to have taken place during treatments in a range of about 40° C., the variation being qualitatively similar to the variation in other properties of copper known to accompany recrystallization. The ranges of temperature are 200–240° C. for 90 per cent reduction and 230–270° C. for 50 per cent reduction. There is no apparent change in the shape of the line at any stage.

It has been reported by Bloembergen and Rowland[3] that the intensity of the absorption line in filed copper increases on annealing by a factor of up to 2, and this is ascribed to the non-appearance of the 'satellite' components of the line in the deformed material because of quadrupole interaction between the nucleus and the electric field gradients produced by dislocations. A similar explanation seems to be difficult to apply in the present case because of the absence of any marked broadening of the line: the observed increase would imply that in the deformed material about one-third of the nuclei are lying in a field gradient large enough to render the satellite components of their nuclear resonance unobservable, while the remaining two-thirds of the nuclei have their resonance virtually unaffected. Such an interpretation seems to imply either a discontinuous distribution of strain in the specimen, or a non-linear relation between strain and quadrupolar interaction energy. The discontinuities in strain which occur in the immediate neighbourhood of a dislocation line are not sufficient to explain the effect, since even if the dislocation density in the deformed material is as high as 10^{11} lines/cm.^{2}, only about 1 per cent of the atoms will lie within 5 interatomic distances of a dislocation line.

Movement of Auroral Echoes and the Magnetic Disturbance Current System

A NUMBER of workers have reported systematic movement of very high-frequency radar echoes associated with auroral ionization. Bullough and Kaiser[1] at Jodrell Bank in England interpreted their results as indicating a westward movement before 2100 hr. local time and eastward thereafter. Unwin[2] at Invercargill in New Zealand, with an aerial directed 20° east of geomagnetic south, recorded radial motions which were northward before about 2230 hr. local time on the average, and southward thereafter. These results are consistent with those of Bullough and Kaiser. Recently, Nichols[3] in Alaska has recorded Doppler shifts with two aerials directed 30° each side of geomagnetic north, from which it was possible to determine an absolute direction and velocity. On most occasions the major component was in an east–west direction. Bullough *et al.*[4] at Jodrell Bank and Gadsden[5] at Invercargill have found a very good correlation between the occurrence of echoes and local magnetic activity. Further, Kaiser[6] found a good correlation between the mean component of radial velocity of echoes (in a direction 50° west of geomagnetic north) and the mean vertical component of the magnetic disturbance vector at Eskdalemuir for the days on which echoes were observed at Jodrell Bank.

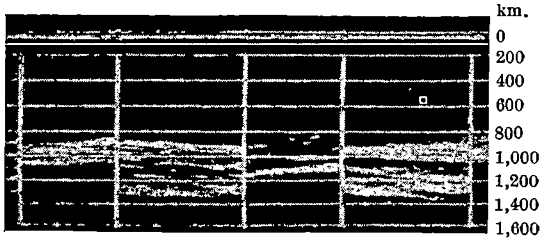

Fig. 1. Range – time record with antenna beam alternately oriented on 175° (for 6 min.) and on 240° (for 4 min.). Time increases from left to right

From this type of evidence it has been suggested by both Bullough *et al.*[4] and Nichols[3] that the movements observed are probably those of the electrons in the magnetic disturbance current system as deduced by Vestine *et al.*[7] from magnetic observations. Nichols calculated a current density of 10^3 amp./km. of latitude, which is of the same order as that deduced from magnetic observations in the auroral zone. The present communication gives further evidence that the movements of echoes can be identified with the disturbance current system, and shows that there is rough quantitative agreement between the two phenomena.

Since May 1958, the radar at Invercargill operating at 55 Mc./s. has been arranged so that the centre of the antenna beam is oriented alternately on geographical bearings of 175° (for 6 min.) and 240° (for 4 min.). The orientations have been chosen to avoid a region of low probability of echoes centred at 210° approximately[8]. An example of a range–time record obtained with this programme is shown in Fig. 1. Consistent radial velocities in each direction are apparent over a period of 20 min., and it is justifiable to calculate an absolute velocity and direction from the radial components read from each consecutive pair of records. In the preliminary calculations no corrections have been made for the fact that the geographical direction of the radar beam varies slightly with range owing to the curvature of the Earth. This change is quite negligible at a bearing of 175°. At 240° it amounts to 10° at 1,200 km., which is small compared with the radar beam-width of 25°.

A histogram of all absolute directions observed between May and August is shown in Fig. 2*a*. They have been calculated separately for the range-intervals 0–400 km., 400–800 km. and 800–1,200 km. from the radar, but there is no systematic change in direction with range. The bulk of the directions measured are close to local magnetic east–west. On any one occasion the change from westerly to easterly movement during the night is quite distinct, though it may

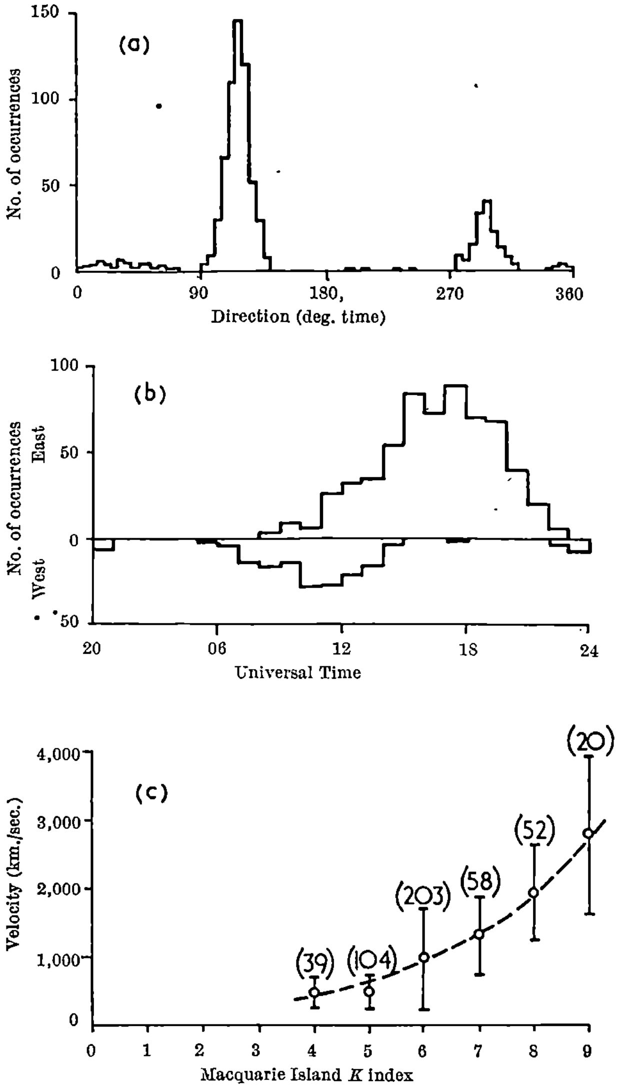

Fig. 2. Movement of echoes: (*a*) Number of occurrences vs. direction; (*b*) number of occurrences containing an easterly or westerly component in the direction vs. Universal Time; (*c*) Average velocities in the 800–1,200 km. range-interval vs. Macquarie Island *K* index. Limits are standard deviations in velocities and bracketed figures are the numbers of cases

occur at any time between about 1030 and 1400 U.T., as shown in Fig. 2*b*. The small number of points between 0 hr. and 0700 hr. U.T. is due to the fact that echoes are normally diffuse at this time[2] and do not reveal sufficient structure on a range–time display to derive an absolute velocity and direction by this method.

There is a wide scatter in the absolute velocities calculated, but in general they increase with the degree of magnetic activity. The average velocities of echoes in the range-interval 800–1,200 km. from the radar are shown plotted against Macquarie Island *K* index in Fig. 2*c*. Macquarie Island is 1,095 km. from radar on an azimuth of 214° geographic.

It has been shown[2] that the echoes come from a layer between a few kilometres and 25 km. thick centred at a height between 110 km. and a little more than 120 km. Recent rocket measurements by Meredith *et al.*[9] at Fort Churchill have revealed the existence of a current at a height of 120 km. during a magnetic disturbance. This evidence, combined with that from previous work discussed above, leaves little room for doubt that the observed movement of echoes can be identified with the magnetic disturbance current system. Following Chapman and Little's view[10] that the average electron density in the auroral zone is 3×10^5/cm.^{3}, a velocity of 1 km./sec. corresponds to a current of 720 amp./km. range for a layer 15 km. thick, assuming the ions are at rest. From Fig. 2*c* a velocity of 1 km./sec. is associated on the average with a K-index of 6 at Macquarie Island. Gadsden[5] has shown that for $K = 6$ the echoes extend to approximately 680 km. from the radar. If we assume further that the near boundary of the echo region corresponds to the boundary of the most intense portion of the disturbance current system, the magnitude of the disturbance vector at Macquarie Island may be found. An approximate calculation gives 375γ for the magnitude in this case, neglecting induced Earth currents. The departure from the quiet day curve for $K = 6$ at Macquarie Island is 360–600γ.

From this preliminary analysis it appears that the ionization giving rise to very high-frequency radar echoes occurs in the most intense portion of the disturbance current system, and that the observed movements of electrons can account for the magnitude of the disturbance vector. This conclusion gives some support to the work of Maeda[11], who found that, in order to interpret the diurnally varying part of magnetic storms by a dynamo theory, a strong polar wind system similar to that deduced here is required. More detailed observations are required to determine whether ions play a significant part.

The work, of which this is a preliminary report, forms part of the research programme of the Dominion Physical Laboratory of the New Zealand Department of Scientific and Industrial Research.

Atmospheric Tides and Earth Satellite Observations

G. V. GROVES, in a recent communication[1], offered an explanation of the marked change in slope of the periodic time curves of the satellites 1958 β, 1958 δ 1 and δ 2. His suggestion of a relatively sharp discontinuity in atmospheric density on passing from the dark to the light side of the Earth is, however, at variance with the work of Kelvin, Rayleigh and Margules on the ultimate effect of solar heating. From their investigations, one would expect, as

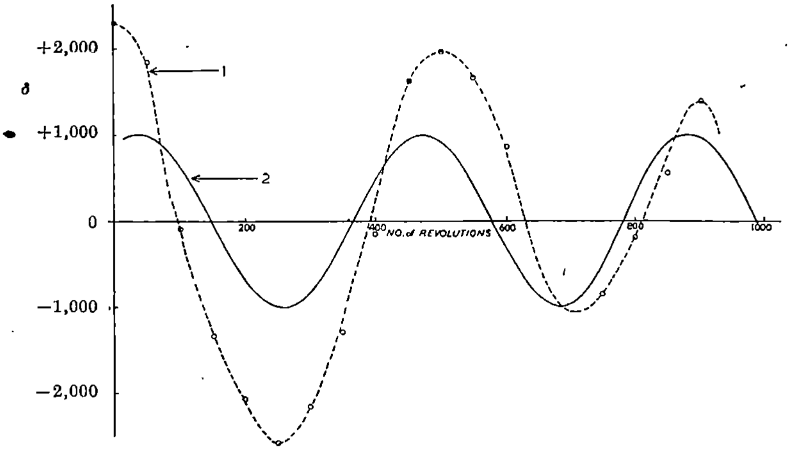

Fig. 1. Satellite 1958 δ 1 ; t_0 = 501·02 days after 1957·0

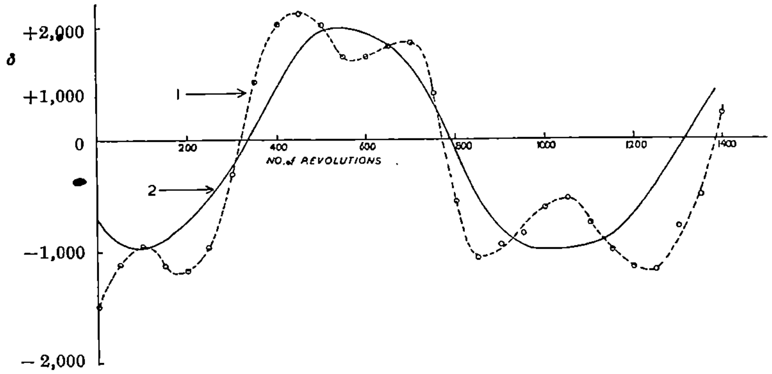

Fig. 2. Satellite 1958 α ; t_0 = 397·16 days after 1957·0

suggested by Kelvin, that the atmospheric distortion produced on the irradiated side of the Earth would lead to a range of Fourier components, that one being most easily detected which corresponded most closely with a natural frequency of tidal waves in the atmosphere. The marked semi-diurnal oscillation in barometric height is ascribed to this effect, and Margules[2] has shown that this corresponds to the natural frequency of waves in a rotating isothermal shell of temperature 298° K.

By a straightforward extension of Margules's analysis, one can investigate the possibility of standing waves of higher multiple frequencies. One finds resonance with the third harmonic in a shell of temperature 470° K., and with the fourth harmonic at a temperature of 590° K. This is relevant to the analysis of observation of satellites, since rocket probes and other sources[3] would suggest temperatures of this order at heights of between one and two hundred miles. More explicitly, one would expect a temperature of 470° K. at a height of about 130 miles, very near the level of the perigee of 1958 δ 1 at the beginning of its life.

In analysing observations of satellites, one has the choice of a variety of parameters, though the periodic time is usually chosen as being the most accurately measurable. Analysis of the dynamics of a satellite orbit under frictional drag, on the other hand, suggests as the most direct parameter the square of the product of the semi-major axis, a, and the eccentricity, e, since it is very nearly a linear function of the time, t. It has the further advantage of being more sensitive to small variations than the periodic time. More precisely, it is convenient to define a parameter u as the ratio ae/a_0e_0 and consider the variation of u^2 as a function of t.

In Figs. 1 and 2, a comparison is given between the departure of u^2 from linearity and the variations to be expected from the third and fourth tidal harmonics respectively. In each case the early part of the orbital development is considered, where u^2 might be expected to be purely linear in form. Only a linear function of t has been subtracted from u^2, the ordinates of the curves 1 being of form $[u^2 - (1 - Kt + C)] \times 10^6$ $(\equiv \delta)$. The comparison curves 2 are the sines of three and four times the difference in right ascension of the Sun and the perigee point respectively.

Fig. 1 refers to the satellite 1958 δ 1 and shows a close agreement between the oscillations of δ and those that might be expected from a third harmonic tide. The sine curve has been given a phase shift of about 70°. One notes further that the oscillations show a decrease in amplitude such as might be expected as the perigee falls out of the region of resonance. The departures of the maxima from precise coincidence are scarcely significant, and are probably the result of a small error in the rate of change of the apex–perigee angle, the effect of which would of course be trebled with the formation of curve 2. The variations of δ nowhere exceed one quarter of a per cent of u, and the regularity of the curve 1 implies a remarkably high degree of precision in the orbital data.

In Fig. 2, for the satellite 1958 α, we find again a close agreement in form between δ and the sine curve, in this case the fourth harmonic with no shift in phase. Superimposed upon the main oscillation in δ is one of much smaller amplitude and higher frequency, which may be identified by its frequency alone as due to an equatorial bulge in the atmosphere of the type caused by the oblateness of the Earth. I have extended my analysis of this effect to meet the criticisms of King-Hele and Leslie[4], and find that this oscillation should have the form :

$$\left(\frac{K}{\omega}\right)\frac{\varepsilon R \sin^2\alpha}{2}\left(\frac{1}{H} - \frac{3}{a_0 e_0}\right)\sin 2\beta$$

where K is the mean value of du^2/dt, ω the mean rate of increase of the apex–perigee angle β, ε and R the ellipticity and radius of the Earth respectively, α the inclination of the orbital plane to the equator and H the scale-height. The amplitude of this oscillation for 1958 α is of order 330 × 10^{-6}, agreeing well with the amplitude of the oscillations demonstrated.

It is difficult to avoid the conclusion that these harmonic tidal waves exist and indeed account for the major anomalies in the orbital observations.

Since the waves are probably operative over a fairly wide vertical range, it is not entirely coincidence that the effects of essentially localized phenomena should appear in two random orbits. As more extended observations become available, it will be of considerable interest to observe the region of decay of the fourth harmonic in the behaviour of 1958 α and the consequent growth of the third harmonic. Such observations would offer a fairly accurate estimate of temperature in the regions of maximum amplitude. Thus we might surmise that the temperature at a height of 224 miles—the perigee level of 1958 α—is of the order of 590° K., implying that the rise in temperature associated with the *F*-layer falls off above 200 miles.

While the major effects modifying the development of satellite orbits are probably now circumscribed, it is a matter of considerable intricacy to predict, for example, the precise values of the periodic time as the orbit develops. On the other hand, the 'young' orbit offers a convenient means for investigating the density distribution of the upper atmosphere.

I am indebted to the Smithsonian Institution for the observations used; without the extreme precision of these values, this discussion would not have been possible.

D. G. Parkyn

University of Cape Town.

[1] Groves, G. V., *Nature*, **182**, 1533 (1958).
[2] Margules, M., Smithsonian Misc. Collections, **843**, 296 (1893).

[4] King-Hele, D. G., and Leslie, D. C. M., *Nature*, **182**, 788 (1958).

From the earliest data on the periods of satellites it was not clear whether the fluctuations in period were due to anything more than the random oscillations of an irregularly shaped body. Changes in the slope of the period–time curves of *Sputniks* 2 and 3 occurred over an interval of a few days, and I remarked that motion of the perigee due to the rotation of the orbital plane seemed to account for the suddenness of the change more easily than the slow drift of the perigee towards the equator. The frequency of these changes seemed related to the crossings of the perigee between the day and night sides of the Earth at three-monthly intervals, suggesting a diurnal variation in air density. As the analysis of data continued, more changes were evident and a periodicity of just less than one month has now been established, and this Parkyn associates with an 8-hr. density variation. The Smithsonian *Sputnik* 3 data, which he presents, show the variation in the period–time curve to be a very smooth oscillation in comparison with earlier data. This is evidence in favour of the phenomenon being a tidal oscillation, and also shows that the effect of the shape of the satellite is mainly averaged out.

One of the first results to be obtained from the launching of satellites was that the air density at 200 km. is several times greater than previously reckoned, due presumably to a higher temperature. Values for the scale-height at 200 km. which I have derived from satellite period–time curves are close to 40 km., and this value is supported by certain rocket measurements. The corresponding temperature is 1,100° K. on assuming the molecular weight for air to be 25 (or 700° K. if we suppose the nitrogen to be almost completely dissociated, which is unlikely). In either case, these values disagree with the values of 470° K. and 590° K., which Parkyn derives from the condition for the third and fourth harmonic oscillations.

Time Relationship of Metre-Wave and 3-cm. Wave Bursts

It is known that solar bursts are observed over a very large range of wave-lengths. A single burst may extend over a large or small fraction of the range from centimetres to metres. Usually, bursts of strong intensity in the centimetre region are associated with great bursts observed on metre waves. It is generally believed that at the time of these bursts, radial ascension of ionized particles excites radio-frequency radiation at different levels in the solar atmosphere. Moreover, there are reasons for thinking that solar radio waves on the lower frequencies are emitted at a higher altitude in the solar atmosphere than those on the higher frequencies. As a result we observe a regular drift of the onset of the bursts towards the lower frequencies. The object of this communication is to discuss a relation existing between the times of commencement of the bursts observed on 3-cm. waves and on metre waves. This work is based chiefly upon measurements of the associated 3-cm. wave bursts made by means of an interferometer[1].

For this study, the data on metre-wave bursts (200 Mc./s.) provided by the observatory of Nera in Holland have been used. For those 3-cm. wave bursts which are accompanied by precursors, the time of beginning of the precursor has been taken as the time of beginning of the burst.

Fig. 1*a* shows the distribution of the times of commencement of the bursts observed on metre waves relative to those of the associated 3-cm. wave bursts. It will be seen that the metre-wave bursts often follow the associated 3-cm. wave bursts. Our results thus confirm that in the majority of cases the solar bursts are excited by the radial ascension of ionized particles in the solar atmosphere. It is also seen that the delay in time varies between zero and about 20 min. The average delay is about 3 min., corresponding to a velocity of radial movement of the order of 500 km./s.

In order to examine whether the delay in time depends on the dimensions of the bursts, the 3-cm. wave bursts associated with metre-wave bursts have been arbitrarily divided into two classes: (*a*) bursts having at the maximum intensity an apparent diameter less than 1·5 min. of arc on 3-cm. waves, and (*b*) the bursts having at the maximum intensity an apparent diameter greater than 1·5 min. of arc. Figs. 1*b* and 1*c* show the corresponding distributions of the delays of the metre-wave bursts relative to the 3-cm. wave bursts. It is seen that the delay has a tendency to be less for the bursts of smaller apparent diameter. The majority of cases in which the time-difference is small belong to class (*a*), whereas most of the cases observed where the time-difference is great belong to class (*b*). The average value of the delay for these two classes of bursts are of the order of 1 min. and 8 min. respectively. The corresponding velocities of the radial movement are of the order of 1,500 km./s. and 200 km./s. respectively.

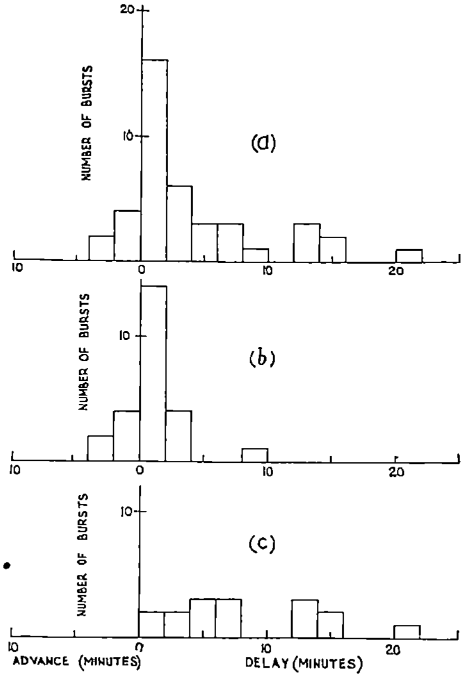

Fig. 1. Distribution of difference in time of commencement of metre-wave bursts relative to associated 3-cm. wave bursts: (*a*) all bursts, (*b*) bursts of diameter < 1·5 min. of arc on 3-cm., and (*c*) bursts of diameter >1·5 min. of arc on 3-cm. radiation

Typical bursts observed on 3-cm. wave-length, the equivalent temperatures of which can reach[2] 10^7 °K., are generally compared with bursts of types II and III usually observed on metre waves. However, it is difficult to identify without ambiguity these 3-cm. wave bursts with one or other of these types. In reality, the comparison between the 3-cm. wave bursts and those observed on longer wave-lengths shows that certain bursts occur almost simultaneously on all the frequencies and are consequently identifiable with bursts of type III. But on metre waves, the bursts of type III last only a few seconds, whereas the bursts observed on 3-cm. waves generally last several minutes. The longer duration of 3-cm. wave bursts agrees better with bursts of type II, which correspond to much greater time delays.

The statistical coincidence of bursts observed on 3-cm. waves and on metre waves shows that the two events have a tendency to occur almost simultaneously, that is to say, correspond to a rapid ejection (at a velocity greater than 1,000 km./s.) when the emissive region is of small diameter, whereas the delay in commencement of metre-wave bursts relative to 3-cm. wave bursts is greater (corresponding to velocities of the order of 500 km./s.) when the emissive region is of large diameter.

The work reported here was carried out at the Meudon Observatory under the guidance of Dr. J. F. Denisse, to whom I express my grateful thanks.

Atmospheric Dust and Fluorescence

Many chemicals and minerals show a bluish fluorescence that can be destroyed by strong heating but is regenerated, after exposure to the air, by lesser heating[1]; I have called this reversibility of fluorescence by annealing. Stimulated by the well-known experiments of Ewles, I ascribed this to the action of adsorbed water, but recent experiments have shown that this interpretation is not sufficient and that the effect is due to dust most likely of organic origin deposited from the atmosphere; subsequent heating causes an interaction between this dust and the inorganic powder (SiO_2,Al_2O_3) used in these experiments, and this gives rise to stronger fluorescence.

The bluish fluorescence of 'pure' water[2] and of snow[3] is now also found to be due to such dust. For the fluorescence that can be destroyed by heating of magmatic minerals such as many feldspars that show no radiophotoluminescence, adsorbed water (Ewles effect) still seems the most plausible explanation; the presence in these minerals of traces of organic substances is, however, not impossible either, according to Oparin[4].

A more detailed report of this work will appear in the *Wiener Anzeiger*.

The Three-dimensional or Solid-Image Microscope

In a recent communication[1] Gregory and Donaldson describe a prototype microscope which produces a three-dimensional image. In this instrument the microscope and the viewing screen oscillate relative to the object so that the microscope scans the object in depth and the viewing screen follows in phase the real image produced. The frequency of the motion is such that an apparent image of each successive plane is maintained in space without appreciable flicker because of the retention of the image by the eye. Reasonable success was claimed at low magnifications, × 20 being about the greatest useful magnification.

I have experimented with a somewhat simpler apparatus lacking the elegant device of the vibrating image screen. In this case the aim was to increase the depth of field at high magnifications by superimposing on the one virtual image plane, repetitive images of successive planes scanned in depth. This would, for example, allow the contents of a cell to be examined at the one focus under a magnification of × 1,000. Another important use for such an instrument would be the scanning of thick emulsions for particle tracks.

As with Gregory and Donaldson's instrument, the object is held to a sinusoidal oscillation along the optical axis by an alternating magnetic field. The period of the motion is 50 cycles/sec. using a tensioned diaphragm. This is powered by a hollow polarized solenoid surrounding the top of the condenser. The amplitude is controlled with a variable resistance in the low-voltage supply to the vibrator. With the present apparatus a depth of 20µ can be scanned without undue image distortion. However, this is approaching the limit using oil immersion with a 50-cycle/sec. frequency. As Gregory and Donaldson mention, without correction the image in the central region of the scan would be weak, while that at the limits would be very bright by comparison. In the present apparatus the image brightness is rendered uniform by changing the phase so that the lamp brightness is proportional to the velocity of the scanning plane. By suitable adjustment of the impedance of the vibrator supply circuit, this supply is displaced some 80° out of phase with the supply to the microscope lamp. Thus, allowing for the lag in the filament temperature, the brightness increases with the velocity of the scan and falls to a minimum at the end of the stroke where the velocity is momentarily zero. Further critical control can then be exercised by varying the current to the lamp, thus altering the hysteresis in the filament.

The apparatus can be adjusted to give surprisingly good resolution at magnifications of × 1,000, using oil immersion objectives, provided that amplitudes less than about 15μ are used. No trouble was experienced with non-drying immersion oils of normal viscosity. The main difficulty at present is that standing waves and other imperfections leading to non-linear motion are present in the vibrator diaphragm. These may be corrected for any position; but readjustment is required with each new position of the slide. The inherent problem is to provide strictly linear motion without increasing bulk or momentum.

GEOPHYSICS and GEOCHEMISTRY

Remanent Magnetism of the Cretaceous Basalts of Madagascar

A general study of the remanent magnetism of volcanic rocks from Madagascar has been undertaken since the beginning of 1958 under the direction of Dr. H. Besairie, chief of the Geological Department of Madagascar.

From various places in the island, more than a hundred oriented samples have been collected by one of us (L. C.) and seven samples by J. Boulanger and P. Bussiere. Forty samples belong to flows or dykes well dated from the upper Cretaceous. Their ages have been proved to vary between Cenomanian and Santonian[1].

The samples were taken in places widely distributed along the eastern coastal district and the western part of the island. They were generally collected in quarries or trenches, some metres below ground-level, but sometimes at ground-level in river beds. The rocks are dolerites, basalts or sakalavites.

In some places, Ampijoroa, Amborompotsy, Antsalova (part), the directions, as well as the values of the intensities of magnetization, proved widely scattered. Values as high as 33 × 10^{-3} c.g.s. units/gm. were found. It is believed[2,3] that lightning currents were responsible for these magnetizations. For the other places the intensities as well as the directions of magnetizations showed good consistency.

For samples originated from the same flow or dyke, the differences between the individual values obtained and the mean value vary from 0 to 4 deg. for inclination and from 0 to 20 deg. for declination.

According to the places, the mean values found for the intensities of magnetization vary from 0·8 × 10^{-3} to 9 × 10^{-3} c.g.s. units/gm.

The magnetic stability of the samples was tested by E. Thellier's method[4], that is, turning over the sample in the Earth's magnetic field for one to several months and comparing the values obtained before and after turning over. Except for two samples, the magnetization showed no variation.

The nature of the magnetization was tested on some samples by successive heatings in a non-magnetic furnace. Only one Curie point was observed between 400° C. and 600° C. for each sample. The magnetization is thought to be thermoremanent[5] and acquired at the time of cooling of the rocks.

All the samples are magnetized according to the sense of the present geomagnetic field at Madagascar. The mean values of the directions of magnetization for the stable samples at each place are given in Table 1. The inclinations are termed negative when the extremity of the magnetization vector points above the horizon.

Table 1

	Inc.	Dec.
Northern districts		
Sambava	−49° 30′	15° E.
Antalaha	−55°	39° E.
Samanavaka	−48°	18° W.
Central districts		
Fenerive	−62°	19° E.
Andramy	−51°	7° E.
Andafiha	−57°	18° E.
Antsalova	−47°	4° E.
Southern districts		
Manakara	−70°	30° E.
Vineta	−53°	26° E.
Tongobory	−56°	15° E.

The inclinations are systematically steeper by 2–10 deg. than those of the present magnetic field for the places on the eastern coast (Sambava, Antalaha, Fenerive, Manakara), but generally lower for the western districts (the differences from the present magnetic field being less than 7 deg.). Notwithstanding a dispersion of some degrees, the magnetic inclination of the samples increases with increasing latitude.

On the whole there is not much difference between the distribution of the magnetic inclination of the samples and that of the present geomagnetic field in the island, as we noticed in our first studies.

The declinations of the samples are all easterly, except for one place (Samanavaka). They differ widely from those of the present geomagnetic field in the island (which vary from 7° W. to 19° W.), the mean difference being nearly 30 deg.

The calculation of the orientation of the dipole axis corresponding to the magnetization of the rocks gave the values for the co-ordinates of the north geomagnetic pole as shown in Table 2.

Table 2

	Lat.	Long.
Northern districts	70° N.	161° W.
Central districts	70° N.	165° W.
Southern districts	64° N.	177° W.
Mean	68° N.	168° W.

The place calculated is in the vicinity of the Behring Strait (Fig. 1). S. K. Runcorn[7] has given results he obtained from the Cretaceous Dakota Sandstones the magnetization of which could correspond to a north geomagnetic pole at latitude 77° N. longitude 127° E., the sense of magnetization being

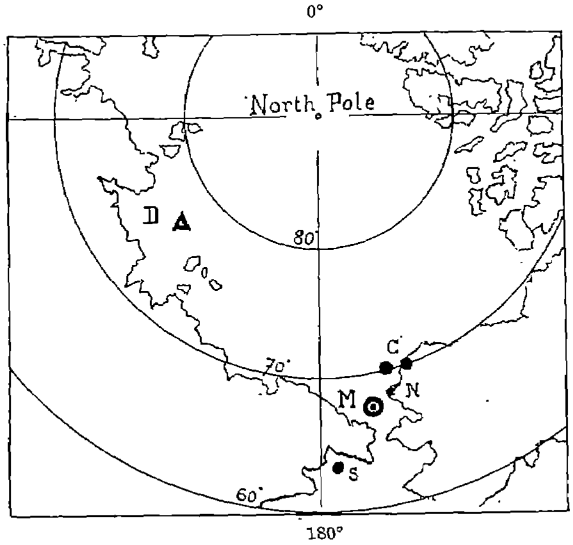

Fig. 1. North geomagnetic poles for Dakota (*D*, △); Madagascar, mean (*M*, ⊙); Madagascar, parts (*N*, *C*, *S*, ●)

reversed compared with that of the present terrestrial magnetic field.

The north geomagnetic pole for Madagascar is thus at a distance of less than 1,500 miles from the north geomagnetic American pole as given by Runcorn, and a little farther from the present geographical north pole.

This can be interpreted in different ways.

(1) The geomagnetic field, though having a dipole character for the main part, may have presented at times in the past a more or less complicated pattern, and the anomalies were smoothed out by taking the means of values scattered over long periods (of perhaps thousands or millions of years).

Therefore our results would have no significance in the perspective of polar wandering or continental drift.

(2) According to Runcorn's hypothesis[8], the mean geomagnetic field obtained by taking the mean of values scattered over a long period is a geocentric dipole field; our results would give the mean orientation of the dipole relative to Madagascar during a part of the upper Cretaceous.

(*a*) If the axis of the dipole had undergone, in the past, angular displacements of limited amplitude comparatively rapidly, say, for example, 10–20 deg. in one or a few million years, then the difference between our results and those of Runcorn could be most simply interpreted by the fact that the samples of America and of Madagascar do not belong exactly to the same period and the results give a picture of the orientation of the dipole at two different periods of the Cretaceous.

The opposed polarities of magnetization for the samples of Dakota and Madagascar give support to this hypothesis.

(*b*) If the dipole axis has undergone in the past displacements only at a slow rate (whether the dipole coincided or not with the axis of rotation of the Earth), we would have to think of relative continental drift for Madagascar and North America. From the Cretaceous up to the present time, according to calculation, the drift for Madagascar would have been about 1,500 miles in amplitude with a direction north-north-easterly.

Though displacements of much larger amplitude have been contemplated for Australia[9] and the Deccan peninsula[10], this hypothesis is considered by us as less likely than that of paragraph 2*a* above.

We wish to express our thanks to Prof. E. Thellier, whose advice was of inestimable value, and to Dr. H. Besairie, who has organized the sampling part of the work and provided the stratigraphical dating. We are also indebted to Prof. H. Dessens, director of the Puy de Dôme Observatory, and to Prof. M. Roques, who have greatly facilitated these studies.

Biological Origin of Manganese-rich Deposits of the Sea Floor

Recently, one of us has advanced arguments[1] in support of the idea that manganese-rich deposits of the sea floor may result from the metabolic activity of a bottom-dwelling organism that derives its nutrients from organic complexes in the water. We present here some new evidence that is relevant to that concept.

On December 18, 1958, at lat. 34° 48′ N., long. 60° 30′ W., in 5,139 m. of water, Mr. L. V. Worthington on *Chain* Cruise No. 2 retrieved about 50 gm. of light tan mud and preserved it for us in borate-buffered (*p*H 8) formalin. The present bottom temperature at this site is 2·3° C. The finer fractions of this material were removed by suspension in water and decantation, and it was possible to isolate a few mgm. of a relatively coarse fraction, which, for the most part, consists of the vacant tests of agglutinated arenaceous (? *Rhabdammina* sp.) and of calcareous Foraminifera. It is of particular interest that almost all the former are coated inside and out with a dark brown or black, earthy or shiny veneer which, by one-dimensional paper chromatography, is seen to be markedly similar in composition to manganese-rich nodules from the Blake plateau, that is, containing appreciable quantities of nickel, cobalt and copper as well as abundant manganese and iron. Treatment with 6 *N* hydrochloric acid removes the dark coating and leaves the Foraminifera tests intact, thus demonstrating that the manganese-rich material was formed as a surface deposit, and not through the capture of pre-existing manganese-rich particles by the living Foraminifera. All manganese-rich particles in this sample apparently were formed by deposition on agglutinated Foraminifera the natural surfaces of which seem to be studded with detrital quartz grains; no comparable manganese-rich deposits are visible on calcareous tests or on isolated sand grains. That the uncoated agglutinated Foraminifera have on their surfaces some protein-rich material is suggested by their adsorption of rose bengal dye[2], and by their reaction with ninhydrin.

To us, these observations support the argument that manganese-rich deposits of the sea floor originate through biological rather than inorganic processes. It would seem that the protein-rich exudate of these agglutinated Foraminifera has provided a favourable substrate which promoted the growth of a colony of organisms that are capable of extracting trace elements from sea water. Siliceous detrital grains on the sea floor, that were lacking in the protein-rich coating, were not such biologically attractive sites, nor were the calcareous tests of other associated Foraminifera.

We are now making preparations for a careful search for the organism which, we expect, is responsible for this type of deposition of trace elements from sea water.

BIOCHEMISTRY

Amino-Acetone : its Isolation and Role in Metabolism

A PRELIMINARY study[1] of the properties of a metabolite produced by washed suspensions of *Staphylococcus aureus* led to the provisional assignment of the structure $CH_3.CO.CH_2NH_2$. This compound, hitherto undetected in Nature, has now been isolated in crystalline form and positively identified as amino-acetone.

The present communication is concerned with the broad details of the isolation and characterization of amino-acetone and, in addition, presents a hypothesis which accounts for its formation and catabolism. It is suggested that this latter involves glyoxalase, an enzyme system which, as yet, has been without a definitive role in intermediary metabolism.

The accumulation of amino-acetone by *Staph. aureus* cells harvested from a bulk culture medium and suspended in phosphate buffer (pH 7·0) containing 0·02 *M* DL-threonine was measured at intervals using a modified picrate reaction method[2,3]. During a 20-hr. incubation a total of 15 m.moles of the compound was produced ; it was isolated by adsorption and elution from 'Amberlite *IRC* 50', fractionation with phosphotungstic acid and finally by chromatography on paper. It was obtained as the pure compound by precipitation from ethanol, as the salt of p-toluene sulphonic acid. This salt was recrystallized twice from absolute ethanol–diethylether as fine white needles—yield 0·39 gm. (m.p. 130·5°).

Elementary analysis gave the following results : amino-acetone p-toluene sulphonic acid salt ; C, 49·2 ; H, 6·3 ; N, 5·9 ; S, 13·0. $C_{10}H_{15}O_4NS$ requires : C, 49·0 ; H, 6·2 ; N, 5·7 ; S, 13·1 per cent.

Amino-acetone hydrochloride was synthesized via acetonylphthalimide[4] and converted to the p-toluene–sulphonic acid salt. This was recrystallized twice from absolute ethanol–diethylether and yielded long thin leaflets with m.p. 130·5°. On analysis it gave the following data : C, 49·2. H, 6·4 ; N, 5·9 ; S, 12·9 per cent. A mixture of the synthetic material, and that isolated from the culture, also melted at 130·5°.

The behaviour of the natural and synthetic materials was identical when chromatographed on paper in a number of solvent systems and when subjected to paper electrophoresis. The identical nature of both products was also confirmed by infrared spectroscopy, which was kindly carried out by Dr. E. Spinner.

It was shown[1] that a compound, now identified as amino-acetone, was formed by *Staph. aureus* either rapidly from threonine alone or slowly from glycine plus glucose, oxygen being necessary in both cases. The question now arises as to the mode of formation of amino-acetone from the two amino-acid precursors. In the case of glycine it would seem likely that it condenses with an acetyl derivative to give α-amino-β-ketobutyric acid in a manner analogous to the formation of α-amino-β-ketoadipic acid from a succinyl derivative and glycine, by the pathway proposed for the synthesis of δ-aminolævulinic acid[1,5–7]. Thus it is envisaged that acetyl-coenzyme *A*, derived from glucose, condenses with glycine as shown in equation 1. The α-amino-β-keto acid so formed would then give rise to amino-acetone by a simple decarboxylation (equation 3). In this connexion it is of interest to note that Gibson *et al.*[5] have independently reported the formation of an amino-ketone from acetyl-coenzyme *A* and glycine by red blood cell preparations. In the case of threonine, a dehydrogenation reaction would yield α-amino-β-ketobutyric acid (equation 2) from which amino-acetone would arise as before.

$$CH_3.CO.S\text{—}CoA + CH_2NH_2.COOH \rightarrow CH_3.CO.CHNH_2.COOH + CoA\text{—}SH \tag{1}$$

$$CH_3.CHOH.CHNH_2.COOH \xrightarrow{-2H} CH_3.CO.CHNH_2.COOH \tag{2}$$

$$CH_3.CO.CHNH_2.COOH \rightarrow CH_3.CO.CH_2NH_2 + CO_2 \tag{3}$$

Regardless, however, of the actual mechanisms involved in the formation of amino-acetone, the appearance of this compound does suggest a role in metabolism, especially as it is known that amino-acetone labelled with carbon-14 is oxidized to $^{14}CO_2$ in the rat[8]. It is suggested that the above facts may be integrated into a metabolic cycle (Fig. 1) which could have a widespread occurrence in animal and bacterial cells.

It is postulated that amino-acetone, formed by the routes described above, is deaminated either by oxidation or transamination to yield methylglyoxal. If formed, methylglyoxal would be rapidly converted to D-lactic acid by glyoxalase and thence to pyruvic acid by the D-lactate dehydrogenase system[9–11]. Both these enzyme systems have a wide distribution in bacteria and in animal tissues.

The postulated cycle provides a new route for the oxidation of threonine and glycine and, in the latter case, an alternative to the succinate–glycine cycle[7]. In addition, it provides an interesting feature, namely, a possible source of substrate, and indeed a purpose, for glyoxalase, an enzyme system the place of which in the metabolic picture has been a puzzle for many years.

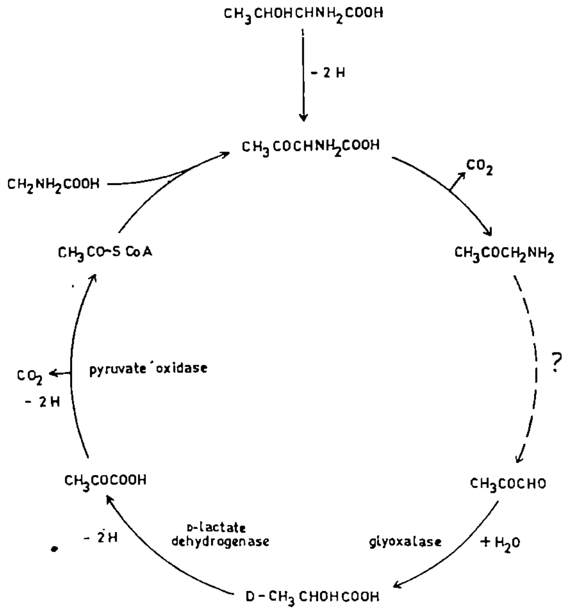

Fig. 1. Postulated amino-acetone cycle. The interrupted line represents a possible deamination reaction

The accumulation of amino-acetone in cultures of *Staph. aureus* is presumably due to the inability of this organism to deaminate the compound. Such a metabolic defect would be entirely in keeping with the limited nitrogen metabolism implied by the strict amino-acid requirements of *Staph. aureus*.

Experiments to test the validity of the above hypothesis are now in progress and, as with full details of the present work, will be reported later.

I wish to thank Prof. A. H. Ennor for the constant encouragement and advice which he has given throughout the course of this work.

Identification of Barbiturates

In Great Britain the most common poisons at the present time are the 5 : 5′ disubstituted barbiturates. The longer-acting barbiturates, barbitone and phenobarbitone, can accumulate in the body when administered in relatively low therapeutic dosage, and concentrations of these drugs in the blood of about 5 mgm./100 ml. do not necessarily imply poisoning. The shorter-acting barbiturates, when taken in therapeutic quantities, however, do not accumulate, and in such cases this concentration would imply that an excessive quantity had been taken.

The only reliable method for the quantitative assay of barbiturate in 5–10 ml. samples of blood is ultra-violet spectrophotometry. The optical density difference at 240 mμ of aliquots at *p*H 10 and *p*H 2 is measured, and, because the E(1 per cent, 1 cm.) values for the various barbiturates are very similar, the total barbiturate concentration can be obtained. In order to assess the likely effect of this concentration it is necessary to identify the ingested barbiturate or at least assign it to the long- or short-acting group. Although slight differences in spectra between the various barbiturates can be detected and used for identification purposes[1], they are of value only if the background absorption is minimal and one barbiturate is present.

It is the purpose of this communication to direct attention to a test which has proved valuable in assisting in the identification of the various barbiturates. Maynert and Washburn[2] showed that concentrated sulphuric acid at room temperature dealkylated some secondary alkyl groups in the 5 : 5 disubstituted barbiturates, and Brooker[3], using treatment with acid at 100° for 1 hr., separated by paper chromatography the products from pentobarbitone and amylobarbitone. Combination of the techniques used by these workers has shown that if the products of the acid treatment at 100° for 1 hr. are, after dilution with water and extraction into ether, examined by ultra-violet spectrophotometry using 0·5 N aqueous ammonia as the solvent, then rapid and easy differentiation of several barbiturates is possible. The results of such treatment on the barbiturates commonly prescribed in the United Kingdom are shown in Table 1.

Table 1

	Result of treatment	λ Maximum of product in 0·5 N ammonium hydroxide
Barbitone Amylobarbitone (amytal) Butobarbitone (soneryl)	Unchanged	240 mμ
Pentobarbitone (Nembutal) Cyclobarbitone (phanodorm)	Attacked	268 mμ
Quinalbarbitone (seconal)	Attacked	Very weak absorption at 240, 266 and 315 mμ
Phenobarbitone	Completely destroyed	Nil

The products from the dealkylation of 'Tuinal' (mixed amylobarbitone and quinalbarbitone) give detectable absorption maxima at 240 mμ and 315 mμ. The absorption from the treatment of seconal is, however, very low and the 315 mμ peak is usually only observable when the extracts are reasonably pure.

The tungstic acid precipitation method followed by isolation of the weakly acidic ether-soluble fraction gives excellent products.

These techniques, coupled with those of paper chromatography[4], have, as yet, not failed to identify unambiguously any of the barbiturates involved in more than one hundred cases submitted to this laboratory in which therapeutic or toxic doses had been ingested.

Isomerization of Poly-*cis*-carotenes by Chlorophyll *in vivo* and *in vitro*

One of the *Chlorella* mutants described by Claes (strain 5/520)[1] synthesizes in the dark certain poly-*cis*-isomers, which are described in the literature as protetrahydrolycopene[2] and prolycopene[3]. In the algal cells the stereoconfiguration is sensitive to light. If oxygen is present, the procarotenes are isomerized in blue but not in red light, yielding the *trans*-forms in the cells. In this case light absorbed by the carotenes is presumed to be responsible for their isomerization.

Not so readily explained was the observation that in the mutant 5/520 the stereoconfiguration of protetrahydrolycopene and prolycopene can become unstable also in red light, which is not absorbed by carotenes. This phenomenon requires irradiation in a nitrogen atmosphere, absence of oxygen alone being insufficient[4].

In view of more recent results, the isomerization of protetrahydrolycopene and prolycopene under conditions of anaerobiosis and red light appears to be sensitized by the chlorophyll present in small amounts in the dark-grown mutant. After chromatographic isolation, both procarotenes show the same behaviour in petroleum ether as in the cell, if the solutions contain some chlorophyll.

Fig. 1 shows the chlorophyll-sensitized isomerization of protetrahydrolycopene in red light (500-W. tungsten lamp, Schott filter *RG* 1 and *KG* 1, distance of the solution from the light source about 60 cm.). Irradiation for 2 hr. results in a change from the spectrum of protetrahydrolycopene to one predominantly that of *trans*-tetrahydrolycopene. If the solution contains no chlorophyll, the procarotene spectrum is scarcely changed under the same conditions of irradiation.

As in the intact cells, chlorophyll-sensitized isomerization of poly-*cis*-carotenes in petroleum ether is inhibited by oxygen. Fig. 2 shows the influence of aeration on the isomerization of prolycopene. The carotene solution contained chlorophyll *a* and was irradiated with red light in the presence of nitrogen or air. Whereas the isomerization is almost at equilibrium after irradiation for half an hour in nitrogen, the presence of oxygen is inhibitory.

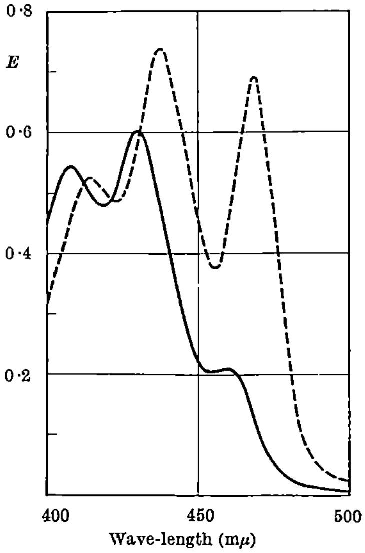

Fig. 1. Absorption spectrum of a mixture of protetrahydrolycopene ($6 \cdot 1 \times 10^{-6} M$) and chlorophyll *a* ($0 \cdot 9 \times 10^{-6} M$) in petroleum ether before, ——, and after, - - - -, irradiation for 2 hr. with red light

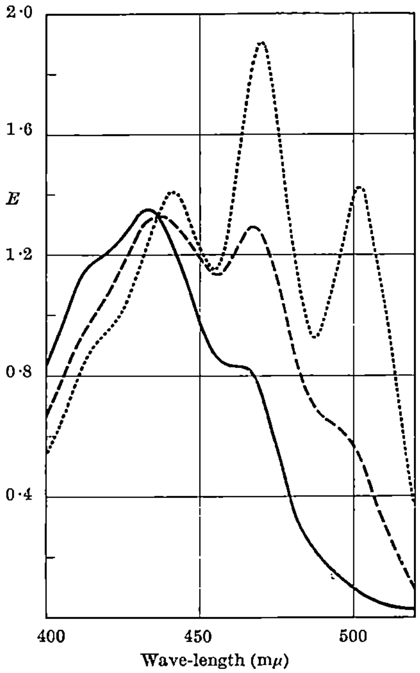

Fig. 2. Absorption spectrum of a mixture of prolycopene ($1 \cdot 2 \times 10^{-5} M$) and chlorophyll *a* ($0 \cdot 2 \times 10^{-5} M$) in petroleum ether before, ——, and after irradiation for half an hour with red light in the presence of nitrogen, ... , or air, - - - -

These findings indicate that in certain conditions (oxygen deficiency and light) the stereoconfiguration of carotenoids in the chloroplasts might be controlled by chlorophyll. The reaction is not limited to the structure of chloroplasts and can be observed outside the cell in pure solutions. Further implications necessarily await more detailed studies of chlorophyll – carotenoid interactions in general.

We are indebted to Miss I. Dobrigkeit for technical assistance.

Green Fluorescence of Guanidinium Compounds with Ninhydrin

Currently available methods for the determination of creatine and other guanidinium compounds are based on non-specific chromogenic reactions. These include the Jaffe, the diacetyl α-naphthol, the Sakaguchi, and the sodium nitroprusside–potassium ferrocyanide reactions. Determination of the individual members of the guanidinium group requires chromatographic separation, chemical degradation, or specific enzymatic destruction of the compound. In a search for a more satisfactory reaction for detection of guanidinium compounds than is at present afforded by chromogenic reactions we have found that ninhydrin (1,2,3-indantrione hydrate) in strongly alkaline media forms highly fluorescent products with guanidine and monosubstituted or N,N-disubstituted guanidines. The most highly fluorescent product is formed with creatine, which can be determined in concentrations as low as 0·07 μgm./ml.; other guanidinium compounds form less fluorescent products.

The Farrand spectrofluorometer model *A*, calibrated by the method of Sprince and Rowley[1], was used for determining excitation and fluorescence spectra. In all determinations, 2 ml. of 0·5 per cent ninhydrin in water and 2 ml. of 1·0 *N* potassium hydroxide were added successively to 2 ml. of an aqueous solution of the guanidinium compound. All measurements were made at 24° C., and the sample was shielded from light except when fluorescence was measured.

Immediately upon the addition of potassium hydroxide to a solution of ninhydrin the five-membered ring is opened to form *o*-carboxyphenylglyoxal[2]. It is apparently the latter compound which combines with the guanidine group to give the fluorescent product; however, any excess *o*-carboxyphenylglyoxal interferes with fluorescence measurements by strongly absorbing the excitation wavelengths used. In the strongly alkaline solution excess *o*-carboxyphenylglyoxal is degraded to *o*-carboxymandelic acid[2], which is colourless, non-fluorescent, and has negligible absorbance at the excitation and fluorescence wave-lengths. Thus it is necessary to delay fluorimeter readings until this excess has been degraded and fluorescence reaches a maximum. With 0·5 per cent ninhydrin and 1·0 *N* potassium hydroxide a plateau of constant fluorescence occurs 9–14 min. after addition of alkali, during which time satisfactory fluorimeter readings may be made. Fluorescence decays to about half the initial value after 1 hr. and to 1/40 after 24 hr. Exposure to sunlight or to higher temperatures accelerates the rate of destruction of the fluorescent material.

The addition product of a guanidinium compound and ninhydrin is a highly fluorescent material with two sharp excitation peaks, at 305 and 390 mμ, the fluorescence at 390 mμ being approximately twice as intense as that at 305 mμ (Fig. 1). The fluorescence spectra have maxima at 495 mμ (Fig. 2). The spectra are similar for the guanidinium compounds tested; however, the amplitude of the peaks varies with the compound. It appears that N,N-disubstituted guanidines form the most highly fluorescent compounds, unsubstituted guanidine the least fluorescent, while monosubstituted guanidines are intermediate. The fluorescence of creatine, using an excitation wave-length of 390 mμ and measuring fluorescence at 495 mμ, is linear from 0·5 μmole to 75 μmole per litre.

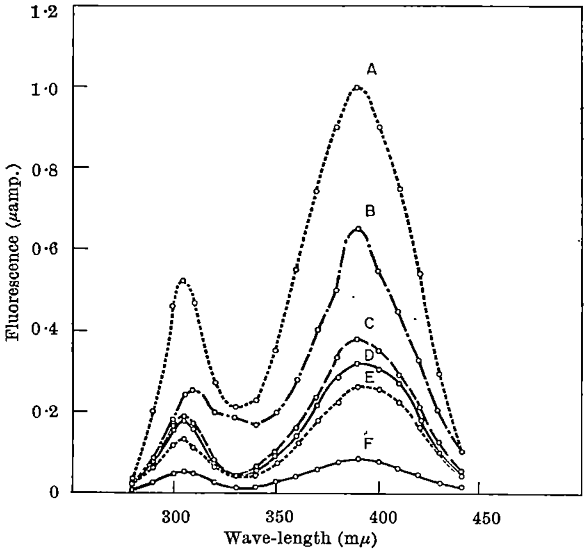

Fig. 1. Excitation spectra of the guanidinium compounds: *A*, creatine; *B*, dimethylguanidine; *C*, guanidoacetic acid; *D*, methylguanidine; *E*, arginine; *F*, guanidine. Each solution contains equal volumes of 0·5 per cent ninhydrin, 1·0 *N* potassium hydroxide and a 50-μmoles/l. solution of the guanidinium compound

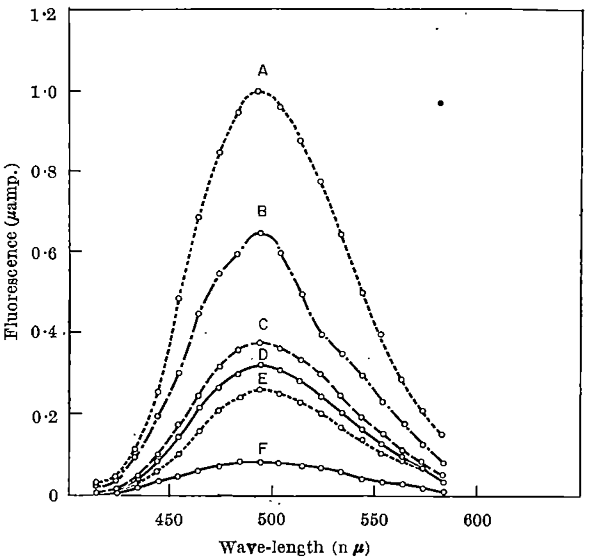

Fig. 2. Fluorescence spectra of the guanidinium compounds. Solutions are the same as for Fig. 1

Apart from the compounds the fluorescence spectra of which are presented in Figs. 1 and 2, creatine phosphate, creatinine, guanine and urea were studied. The fluorescence of creatine phosphate is less than 1 per cent, and the fluorescence of creatinine less than 0·5 per cent of that of an equimolar concentration of creatine. A saturated aqueous solution of guanine gives no fluorescence, nor do ammonium salts in concentrations 100 times that of the guanidinium compounds studied. Urea gives about 1/50,000 the calculated fluorescence of an equimolar concentration of creatine.

In his studies of ninhydrin, Ruhemann[2] noted that guanidine combines with the hydrated 2-carbonyl group of ninhydrin to give a red addition product in alkaline solution. This probably is not the structure of the fluorescent compound, since it appears that formation of the fluorescent addition product occurs after the five-membered ring of ninhydrin is opened, as indicated by the loss of the usual colour reactions of ninhydrin. It appears that the reaction requires at least one free NH_2 group on the guanidinium compound since guanine, creatine phosphate and creatinine do not form the fluorescent addition product. The combination probably occurs at one or both of the adjacent ketone groups of *o*-carboxyphenyl-glyoxal since the yellow colour of this compound caused by the adjacent ketone groups disappears when the addition product is formed.

Although the fluorescent reaction is non-specific among the guanidinium compounds, it provides a marked increase in sensitivity over the chromogenic reactions currently used for the determination of these compounds. Application of the reaction to the determination of creatine and creatine phosphate in biological material is now being studied.

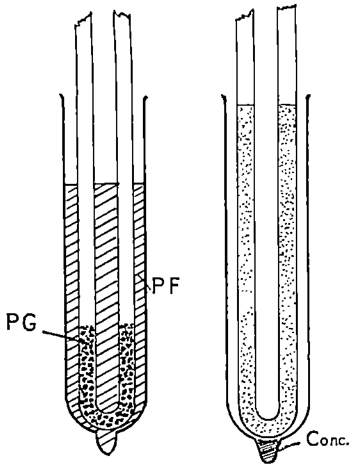
A Simple Method for the Concentration of Fluids containing Protein

THIS method is essentially based on the well-known principle of dialysis against substances of high molecular weight.

Fluid containing protein is placed in a glass tube or container, preferably with a small protuberance at the bottom end having approximately the smallest volume to which the fluid is to be concentrated. The size and shape of the glass container should be such as to provide the greatest possible dialysing surface. Using small glass tubes and narrow tubing, even a few millilitres of fluid containing protein can be successfully concentrated. The polyethylene glycol ('Carbowax' 20 *M*, made by Union Carbide, also available from G. T. Gurr), a waxy, flaky substance, with a molecular weight of 20,000, is broken up and an appropriate quantity of the dry granulated material is poured into the dialysis tubing. This can easily be achieved by inflating the tubing and using a funnel. 'Visking' dialysis tubing was used throughout, but any similar tubing would be suitable. The proportion of polyethylene glycol to fluid containing protein is not critical, but there should not be less than 1 part of polyethylene glycol to 10 parts of fluid. Polyvinylpyrrolidone (PVP) in dry powder form was also tried and gave satisfactory results; it is, however, much more expensive. The dialysis tubing containing the polyethylene glycol is then bent double (or more) and is placed in the glass vessel containing the glycol (Fig. 1). The length of the tubing should be such as to allow for the rising column of water inside it. It is advisable to moisten the polyethylene glycol inside the tubing with a small quantity of water just before it is placed in the fluid containing protein. The level to which the tubing should be pushed down depends on the final concentration required. The concentrating process ceases, of course, when the fluid containing protein reaches the level of the bottom of the tubing. The whole procedure is thus automatic. With larger quantities of fluid the tubing can be bent several times, providing a larger dialysing area and accelerating the process. The electrolyte content of the concentrate will be the same as in the fluid containing protein at the start, as there is a free passage of electrolytes across the membrane.



Before After

Fig. 1. Apparatus for concentrating fluids containing protein. *PF*, fluid containing protein; *PG*, polyethylene glycol; *Conc.*, concentrate

The method is rapid, reliable, and no special equipment is required. It has also the great advantage that the concentrate can be collected from clean glass and need not be scraped out from the inside of a sticky tube. Under suitable conditions a concentration, for example, of 10 ml. of urine to about 0·25 ml. is easily achieved in 3–4 hr. The high efficiency of the method is also due to the fact that the hydrophilic agent, namely, polyethylene glycol, does not contain water and has, therefore, full absorptive capacity. No denaturation effects were observed.

Unfermentable Sugars in Barley Mash fermented by the Amylo Process

IN an earlier communication[1] concerning the production of alcohol from starchy materials by the amylo process, it was demonstrated that sugar consumption with barley fell considerably below that of the other raw materials by failing to exceed 85 per cent even with barley grains from which the bran had been removed. This was attributed to the presence of a considerable amount of unfermentable sugars. We now wish to report on the composition of residual unfermentable sugars in the fermented mash of barley, including the isolation of laminaribiose and of a β-linked glucosyl trisaccharide from this mash.

Polished barley grains were cooked with 0·03 per cent hydrochloric acid at 3 kgm./sq. cm. for 60 min. Alcohol fermentation of the cooked mash (total sugar 10·9 per cent) was carried out by the amylo process with the amylo mould (*Rhizopus javanicus* Takeda) and alcohol yeast (*Saccharomyces cerevisiae* sp.). After completion of fermentation, the mash (total residual sugar 1·6 per cent) was deproteinized and concentrated *in vacuo*. The acidic hydrolysis of this concentrate produced pentose (xylose and arabinose) and glucose as the sugar components detectable by paper chromatography; the pentose–glucose ratio of 44 : 56 was estimated on the basis of the paper chromatographic analysis devised by A. E. Flood *et al.*[2]. The concentrated sugar mixture (300 ml.) equivalent to 4,000 ml. of fermented mash was then separated into xylose, arabinose, galactose (?), three pentosyl oligosaccharides, five glucosyl oligosaccharides and higher pentosyl and glucosyl oligosaccharides by a combination of carbon column[3] and paper chromatographic techniques. Three pentosyl oligosaccharides had R_F

values of 0·29, 0·17 and 0·06 in *n*-butanol/pyridine/water (6 : 4 : 3), respectively. Further investigation on the structure of these pentosyl oligosaccharides was not carried out. Five glucosyl oligosaccharides consisted of two minor components presumed to be *iso*maltose (or gentiobiose) and kojibiose (or cellobiose), and three major constituents (*a*, *b* and *c*) having R_F values of 0·29, 0·16 and 0·05 in the same solvent, respectively. The ratio of *a*, *b* and *c* in the fermented mash was shown by paper chromatographic analysis to be 18 : 48 : 34. The greater part of each of these three sugars was eluted in the pure state (paper chromatography and ionophoresis[4]) from the carbon column ; yields, 1·1 gm. of sugar *a*, 2·8 gm. of sugar *b* and 2·5 gm. of sugar *c*.

Sugar *a* was crystallized from methanol. The crystals were recrystallized from the same solvent : melting point 205–208°, unchanged on admixture with an authentic specimen of α-laminaribiose, $[\alpha]_D^{16} = +24\cdot8 \rightarrow +18\cdot8°$ (*c*, 2·5 in water). Acetylation of a portion of the free sugar yielded the crystals. The crystalline acetate was recrystallized from 95 per cent ethanol ; melting point, 160·5–161·0°, undepressed on admixture with authentic β-octaacetate, $[\alpha]_D^{16} = -28\cdot8°$ (*c*, 2·5 in chloroform).

Sugar *b* was reducing and showed $[\alpha]_D^{16} = +10°$ (equil. : *c*, 3·0 in water). Acidic hydrolysis of sugar *b* gave only glucose on the paper chromatogram (identified as β-pentaacetate). From R_F and the elution behaviour from the carbon column, this substance was presumed to be a trisaccharide. A further indication was that the degree of polymerization calculated from the increase of reducing power[5] after hydrolysis was 2·8. The substance (1 gm.) was submitted to partial acidic hydrolysis with 1·0 per cent sulphuric acid at 100° for 2½ hr. Carbon column chromatography of the solution produced the mixture of disaccharides together with glucose and parent sugar. This mixture was fractionated by chromatography on paper into two components ; the faster-moving component (0·11 gm.) and slower-moving component (0·1 gm.). Both were characterized by conversion into β-laminaribiose octaacetate and β-cellobiose octaacetate, respectively. This result showed that sugar *b* contained laminaribiose and cellobiose moieties. The sequence of linkages was determined by sodium borohydride reduction of sugar *b* to the sugar alcohol and partial acidic hydrolysis of the product. Paper chromatographic analysis revealed that the only reducing disaccharide present was cellobiose, thus proving that sugar *b* was O-β-D-glucopyranosyl-(1 → 4)-O-β-D-glucopyranosyl-(1 → 3)-D-glucose. It also supported the above structure that laminaribiose was the only disaccharide produced by the partial hydrolysis of β-glucosidase (almond emulsin)[6].

Acetylation was carried out with sodium acetate and acetic anhydride at 125–130° for 40 min. Crystalline β-hendecaacetate was formed from 95 per cent ethanol : melting point, 182·5–183·0°, $[\alpha]_D^{25} = -21\cdot7°$ (*c*, 3·0 in chloroform) ; analytical calculation for $C_{40}H_{54}O_{27}$: C 49·69, H 5·63 per cent ; found : C 49·65, H 5·86 per cent. Adding the molecular rotation of laminaribiose and the molecular rotational increment in the series of cellodextrins gives + 12·1°, which is in good agreement with $[\alpha]_D = +10°$ of our trisaccharide. Prof. S. Peat and his co-workers[6], however, reported 3-O-β-cellobiosylglucose (β-acetate : melting point, 108–110°, $[\alpha]_D = -8\cdot3°$) in the partial acidic hydrolysate of lichenin.

Acidic hydrolysis of sugar *c* also gave only glucose. It was shown to be a tetrasaccharide by the method described above. After partial acidic hydrolysis laminaribiose, cellobiose and trisaccharide mixture were detected, in addition to glucose and parent sugar. Consequently, it was inferred that sugar *c* was a tetrasaccharide containing at least one β-1 : 3- and one β-1 : 4-linkage.

The amylo process with starch materials other than barley showed 94–96 per cent sugar consumption and did not leave the above β-linked glucosyl oligosaccharides in such amount as is detectable on paper chromatogram. Further, the amount of these oligosaccharides isolated from the fermented barley mash was sufficiently large to preclude the possibility of their being products of transglucosidation by amylo moulds, since their power of transglucosidation is known to be extremely weak[7]. Furthermore, the main products of acid reversion of glucose include 1 : 6-linked disaccharides[8] and lævoglucosan[9]. In the actual experiment, no lævoglucosan was detected and only infinitesimal amounts of 1 : 6-linked sugars (*iso*maltose or gentiobiose) were isolated. Recently, R. A. Aitken *et al.*[10] detected laminaribiose and cellobiose in the enzymatic hydrolysate of barley glucosan. G. C. Aspinall and R. G. J. Telfer[11], who also studied the methylation of barley glucosans, indicated the presence of a polysaccharide containing unbranched chains of β-D-glucopyranose residues with approximately equal proportions of 1 : 3- and 1 : 4-linkages. From these facts, our β-linked glucosyl oligosaccharides are thought to be derived from the fragmentation of a β-glucosan.

We wish to thank Prof. T. Asai, Prof. K. Aso, Dr. K. Shibazaki and Mr. K. Mutai, president of the Fermentation Research Institute, for their helpful advice and interest in this work.

Selective Inhibition of Formation of Deoxyribonucleic Acid in *Escherichia coli* by Mitomycin *C*

Previous studies with mitomycin *C*, a new antibiotic isolated from *Streptomyces caespitosus* by Wakaki *et al.*, have demonstrated antibacterial activity as well as a marked antitumour effect[1,2]. In the course of investigating the mechanism of the actions of mitomycin *C*, evidence was obtained that this antibiotic selectively inhibits the synthesis of deoxyribonucleic acid in *Escherichia coli B*.

Cells grown in a salts–glucose synthetic medium were harvested during the logarithmic phase, washed and resuspended in a similar fresh medium with or without mitomycin *C*, to give a concentration of 1×10^8 cells per ml. 20 ml. of the bacterial suspension were incubated at 35° with shaking, and aliquots of 2 ml. were taken at the intervals shown, and analysed for turbidity, nucleic acid and protein. Turbidity was measured photometrically at 660 mμ and viability of the cells was measured by plating. Ribonucleic and deoxyribonucleic acid were assayed by the orcinol and diphenylamine methods respectively, after extraction from the acid-insoluble precipitates of bacteria with hot 6 per cent perchloric acid. The protein content was measured by the Folin method.

Table 1. EFFECT OF MITOMYCIN *C* ON THE GROWTH, PROTEIN AND NUCLEIC ACID SYNTHESIS OF *E. coli* B

Mitomycin *C* in suspension (μgm./ml.)	Time incubated (min.)	Turbidity E_{660}	Protein (Folin reaction) E_{660}	Ribonucleic acid (orcinol reaction) E_{660}	Deoxyribonucleic acid (diphenylamine reaction) E_{600}
0	0	0·090	0·070	0·110	0·030
	30	0·125	0·105	0·160	0·045
	60	0·180	0·150	0·225	0·065
	90	0·265	0·210	0·315	0·090
0·1	0	0·090	0·065	0·110	0·030
	30	0·135	0·100	0·155	0·030
	60	0·185	0·140	0·230	0·030
	90	0·225	0·190	0·320	0·030

Alterations in the bacteria during exposure to 0·1 μgm./ml. of mitomycin *C* are illustrated in Table 1. A normal increase in turbidity was observed during the first 60 min., after which the rate of increase in turbidity slowed down. However, after 90 min. of incubation there were only 1×10^6 viable cells/ml. as measured by plate count. Deoxyribonucleic acid formation was completely inhibited by the presence of mitomycin *C*, although synthesis of protein and ribonucleic acid was unaffected as compared with that of an unexposed culture during the test period. The inhibition of synthesis of deoxyribonucleic acid in the presence of the antibiotic could be reduced to some extent by the addition of baker's yeast extract to the incubation medium. The inhibitory action of mitomycin *C* on synthesis of deoxyribonucleic acid was observed even after removing the cells from mitomycin *C* and washing with saline.

Experiments on the effects of this compound on synthesis of deoxyribonucleic acid with the purified Kornberg enzyme are now in progress in an attempt to clarify the exact mechanism of the inhibitory action. A more detailed report will be published elsewhere.

ANIMAL PHYSIOLOGY

Biosynthesis of Ovalbumin

THE problem of the biosynthesis of ovalbumin is interesting since this protein seems to be synthesized from a non-homogeneous pool of intermediary peptides[1-3]. We have studied the biosynthesis of this protein *in vivo* by the laying hen using L-cystine-^{35}S and $Na_2{}^{14}CO_3$. Selected birds were given these labelled substances and blood was obtained at stated intervals, either by heart puncture or from the wing vein. The time of laying the egg was carefully noted and ovalbumin was isolated from the egg white by ammonium sulphate fractionation. Serum globulin was isolated by precipitation with an equal volume of ammonium sulphate, while the total proteins were obtained by precipitation with trichloracetic acid to a final concentration of 5 per cent. In both cases the precipitates were repeatedly washed with 5 per cent trichloracetic acid to remove any co-precipitated amino-acids.

The results shown in Tables 1 and 2 indicate that the ovalbumin of eggs laid within 24 hr. of administration of the isotope was not significantly radioactive. The radioactivity of the ovalbumin is not high when that of the serum amino-acids is high. But the ovalbumin from eggs laid after 30 hr., when the radioactivity is found in the serum proteins and not in the serum amino-acids, is markedly radioactive. This shows that ovalbumin is not synthesized by the oviduct from the serum amino-acid pool, but probably from derivatives of serum proteins or intermediary peptide pools. The mechanism of the biosynthesis of ovalbumin is thus different from that of milk proteins, which have been shown to be derived from serum amino-acids[4].

Table 1. INCORPORATION OF CARBON-14 DIOXIDE INTO SERUM AND EGG PROTEIN

Bird No.	Time from administration of $^{14}CO_2$	C.p.m./ml. of serum, non-protein part	C.p.m./mgm. total serum proteins	Time of laying the egg from time isotope was given (hr.)	C.p.m./mgm. of ovalbumin isolated

2	8	3,300	237	22	nil
	25	1,930	230		
	45	400	266		

It could be argued that the oviduct might store serum amino-acids as a reserve and utilize them after 24 hr. That such storage of free amino-acids is not the case seems to be indicated by the following facts: (1) boiled juice from the oviduct has a very small content of free amino-acids as shown by the ninhydrin test; and (2) ovalbumin from eggs obtained as much as 48 hr. after the administration of the isotope is still radioactive. By this time the serum amino-acids have lost a considerable part of their radioactivity. It is difficult to appreciate that the amino-acids stored in the oviduct are not in equilibrium (even with a low exchange) with those in the serum.

However, such storage of a polypeptide precursor in the oviduct is not improbable, because our *in vitro* studies (Table 3) seem to indicate that the synthesis of ovalbumin by washed oviduct preparations is fairly independent of added amino-acids, adenosine triphosphate, etc. The amount of ovalbumin syn-

thesized in the *in vitro* incubation of oviduct with a complete medium, or in the absence of any additions, was estimated by antigen analysis techniques using rabbit anti-hen egg albumin sera. These sera were standardized previously with pure ovalbumin. These results show that the oviduct can synthesize ovalbumin without any further additions, and also that hydroxylamine does not have strong inhibitory action on this synthesis. This may possibly suggest a conversion of an ovalbumin precursor to ovalbumin not dependent on added adenosine triphosphate.

We wish to thank the National Institutes of Health, Bethesda, Maryland, for a grant in aid of this research.

Molecular Orientation at the Surface of *Amoebae* during Pinocytosis

PINOCYTOSIS[1] or cell-drinking appears to be a method for the uptake of molecules to which the cell membrane is impermeable[2]. In *Amoebae* the phenomenon may be identified by the formation of many short pseudopods each containing a central channel 1μ or more in diameter; droplets of fluid pinch off from this channel and migrate into the interior of the cell[3]. Recently, pinocytosis has become the subject of considerable physiological experimentation[2,4–6]. By means of fluorescein-labelled proteins, Brandt[5] demonstrated that proteins inducing pinocytosis are attached to the cell membrane of *Amoebae*. Schumaker[6] obtained results on the rate of uptake of radioactive proteins which lead to a similar conclusion.

In order to speculate intelligently about the induction of pinocytosis it would be of interest to know more about this attachment. Some information can be obtained from polarization microscopy, which will reveal the molecular orientation of the cell membrane and, in certain instances, of substances attached to the surface. The present preliminary communication describes interactions between pinocytosis-inducers and the surface of *Amoeba proteus* determined by the use of the polarizing microscope.

Mitchison[7] confirmed the well-known natural surface birefringence of *Amoebae* and showed that various basic dyes are oriented at the surface in an orderly molecular array *in vivo*. The surface orientation of these anomalously birefringent basic dyes may be shown by the striking differences in colour (for example, blue versus yellow) that appear when the surface faces different quadrants of the compensated polarizing microscope.

The first experiments were simple comparisons of cells in their inorganic culture medium and cells pinocytosing in either albumin or ribonuclease. There were no qualitative differences in the surface birefringence of the cells in the different media. The surfaces of the pinocytosis channels also showed the same molecular orientation as the rest of the cell surface (Fig. 1*a* and *b*). Hence, it may be concluded that there is no major re-arrangement of the orientation of molecules in the cell membrane. Quantitative studies of possible small differences do not appear to be feasible, because the errors in measurement[8] would vary as the square of the inaccuracy in determining the diameters of both the narrow channel and the wider pseudopod.

In the course of repeating Mitchison's experiments on the surface orientation of anomolously birefringent basic dyes[7], it was found that at higher concentrations toluidine blue not only became attached to the surface of *Amoebae* in a definite molecular orientation but also induced pinocytosis. There were no qualitative differences in dye orientation between the channels and other parts of the cell.

Two types of qualitative changes that have been described previously by Mitchison were seen in random parts of some cells. The first was the loss of dye-binding capacity but not natural birefringence accompanying surface 'bubbling'. The second was a 90° change in the orientation of the dye molecules with respect to the visible edge of the cell as evidenced by a colour change.

When the cells were first placed in dye solutions there were often strong differences in colour intensity between different parts of the surface of the same cell. Sometimes these differences could be discerned as absorption differences with transmitted (unpolarized) light. The increase in intensity could be watched on parts of cells which did not change shape. These observations indicate both local surface differences in the number of available dye-binding sites and a time-dependent attachment.

In order to test the hypothesis that proteins might also be absorbed to the same specific surface groups

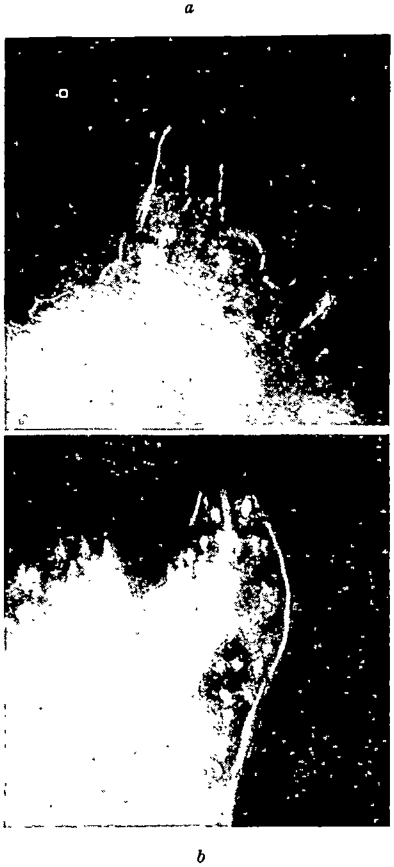

Fig. 1

during the induction of pinocytosis, a series of experiments was performed using both proteins and toluidine blue. Three designs were employed: simple competition with both pinocytosis-inducers present, addition of the dye to a protein solution containing pinocytosing *Amoebae*, and addition of protein to a dye solution containing pinocytosing cells. Four proteins were tested separately: albumin, protamine, ribonuclease, and trypsin. In all instances there was competition dependent on concentration between the dye and the protein for surface sites as evidenced by the comparison of natural surface birefringence with the anomalous birefringence colours of the attached dye. Ribonuclease and protamine, two basic proteins, appeared to be more effective than either albumin or trypsin; however, the relative effectiveness will require further examination under conditions of varying *p*H and salt concentration.

The competition experiments suggest that proteins are not only attached to the cell surface[5,6] but also that they are attached in an orderly molecular array. Since only basic dyes are oriented at the cell surface[7] and the basic proteins appear to compete most favourably with these dyes, it is also reasonable to postulate that the sites on the cell surface are acidic.

This method, while indirect, is highly sensitive, and should prove to be a valuable tool for the further study of surface interactions in the induction and inhibition of pinocytosis.

This work was performed during the tenure of a research fellowship of the National Cancer Institute of the U.S. Public Health Service. I wish to thank Dr. J. M. Mitchison not only for instruction in the techniques of precision polarization microscopy but also for suggesting re-examination of the dye orientation. I am also grateful to Dr. Mitchison, Prof. M. M. Swann, Dr. N. de Terra, and Prof. H. Holter for stimulating discussions about these problems.

Re-utilization of Lymphocyte Remnants by Reticular Cells

The behaviour and function of lymphocytes were discussed at a meeting in London in 1957[1]. As a consequence of the results of experiments with radioactive labels[2], the hypothesis of continuous re-utilization of large fragments of lymphocyte nucleic acids or nucleoproteins during the formation of new lymphocytes was generally accepted. Morphological support for this view has been put forward by Trowell[3], who has demonstrated that the reticular cells are differentiated into large lymphocytes in the course of phagocytosis of dead lymphocytes *in vitro*. We have been able to supplement his findings by similar observations made during the time of heightened lymphocyte dissolution *in vivo*.

I have studied the experimentally elicited disintegration of lymphocytes in spleen lymphatic nodules. The mice of *H*-strain were subjected to total-body irradiation of 500 r., 650 r., and 750 r.; rats of the Wistar strain were subjected to formaldehyde stress and normal and adrenalectomized ones to hydrocortisone ('Scheroson *F*' Shering, 4 mgm./100 gm. body-weight). X-rays were delivered at the rate of 45 r./min. (180 kV., 15 m.amp., filters 1 mm. aluminium and 0·5 mm. copper, target distance 55 cm.). The spleens were fixed in Helly–Maximow's fluid and dyed by azur II – eosin, methyl green – pyronin and by the Feulgen nuclear reaction. The specificity of ribonucleic acid staining by pyronin was controlled by means of the perchloric acid extraction technique.

In the course of dissolution of the lymphocytes, the cytoplasm of reticular cells became deeply basophilic. At the same time their nuclei and nucleoli enlarged. The strikingly close association of lymphocyte dissolution with transformation of reticular cells was seen under the following conditions.

The formaldehyde injection may elicit a stress disintegration of lymphocytes in light centres and a marked swelling of lymphoid tissue of spleen lymphatic nodules[4]. At 6 hr. after the injection, extensive masses of large immature lymphoid cells are formed at the periphery of centres. They originate in the reticular cells occupying the corresponding part of light centres in non-stressed rats. Quite similar events are observed after the injection of hydrocortisone in adrenalectomized rats. A pronounced swelling of lymphoid tissue and disintegration of lymphocytes in the centres of the nodules occur within 3 hr. At 6 hr., groups of immature cells having large nuclei and intensive pyroninophilic cytoplasm develop. In normal rats treated by hydrocortisone, however, both the disintegration of lymphocytes and swelling of lymphoid tissue are negligible, and the immature cells fail to be differentiated.

In comparison with stress, the transformation of reticular cells is shown more clearly in a denuded reticular network of spleen lymphoid tissue of an irradiated animal. Most lymphocytes undergo disintegration and fill the spaces of the reticular stroma with numerous fragments. No phagocytosis takes place. The reticular cells adjacent to fragments show a gradual rise in cytoplasmic basophilia and the nuclei and nucleoli become enlarged as in immature cells. During this change they differ essentially from those originally building up the nodule reticulum. In the transition stages a pyronin-staining reaction may be seen around the nucleus, leaving the rest of the cytoplasm and the cytoplasmic processes almost unstained. The incidence and/or intensity of pyroninophilia of reticular cells seem to depend upon integrity of a humoral union with red pulp, in addition to an abundance of lymphocyte remnants. The pyroninophilia appears to be more intense at the periphery of the nodules than in destroyed light centres, separated from the red pulp by a dense reticular envelope. Swelling of the lymphoid tissue accompanies both the dissolution of lymphocytes and the increasing reticular pyroninophilia, as it does in the case of unspecific stress.

Eventually, the enlarged pyroninophilic reticular cells develop into more differentiated ones, mainly into immature plasma cells, but a few form large and medium-sized lymphocytes. Immature plasma cells originating in this way may occupy extensive areas of destroyed lymphoid tissue from as soon as 12 hr. after irradiation.

In mice irradiated with lethal doses of 650 r. or 750 r., and so deprived of most of their lymphocytes, the reverse 'differentiation' can be observed. At the time of disappearance of lymphocyte debris the large groups of immature cells may survive in the nodules. However, the basophilia of their cytoplasm begins to diminish until it disappears in 24–48 hr. after the irradiation. The immature cell groups undergo a dedifferentiation into a voluminous cytoplasmic syncytial mass which is not stained with pyronin. The large vesicular nuclei, in their persistence at the time of loss of pyronin stainability and of cell coupling into a syncytial feature, are proof that dedifferentiation has occurred.

These observations indicate the close relation between the dissolution of lymphocytes and the transformation of resting reticular cells into cell elements with a high power of differentiation, in accordance with the apparent signs of immaturity. The intimate local and temporal coincidence of both the dissolution of lymphocytes and the transformation of reticular cells are striking. In addition, the reverse, that is, the dedifferentiation, can also be found. The striking incidence of numerous cell fragments in proliferating centres of lymphatic nodules is stressed by DeBruyn[5] and by Ringertz and Adamson[6]. Furthermore, Dougherty and White[7] describe both dissolution of lymphocytes and an increased number of immature plasma cells as the result of adrenocortical stimulation.

These observations and results recorded in the literature suggest that dissolution of lymphocytes produces a humoral factor—probably a derivative of their nucleic acids or nucleoproteins—with the ability to maintain the cytological characteristics of immature cells on the normal level, in participating in their nucleic acid metabolism. Raising the production of such a factor in the course of heightened lymphocyte dissolution, new resting cells become transformed into immature ones; decreasing production in the case of lymphocyte deprivation, a dedifferentiation of immature cells into reticular ones occurs.

Further details of this work will be published elsewhere.

A Survival Curve for Mammalian Cells irradiated *in vivo*

HIGH density single-cell suspensions of transplantable mouse leukæmia cells have been prepared from the infiltrated livers of leukæmic *CBA* mice. The density of morphologically healthy malignant cells in a suspension was determined by counting by phase-contrast microscopy, and selected serial dilutions of the counted suspension were injected intraperitoneally into groups of isologous mice. From the leukæmia mortalities in the injected groups the mean number of leukæmia cells required to convey leukæmia to half a group of injected mice (the *TD*50) was calculated by the method of Reed and Muench[1]. In six such bio-assays of suspensions from the livers of untreated leukæmic mice, *TD*50 values ranging from 0·7 to 3·0 (mean 2·0) were obtained.

The densities of morphologically intact leukæmia cells in suspensions prepared from the livers of leukæmic mice within a few minutes of the end of their exposure *in vivo* to cobalt-60 gamma whole-body radiation, delivered at a dose-rate of about 75 r./min., were found not to have been influenced by the preliminary irradiation of the mice. Bio-assays of suspensions from such irradiated mice, however, gave *TD*50 values which were raised above the mean *TD*50 (2·0 cells) obtained for suspensions from unirradiated leukæmic mice and which were a function of the radiation dose. This is to say that a proportion of the exposed leukæmic cells were found to have lost their reproductive integrity soon after irradiation without having sustained visible damage.

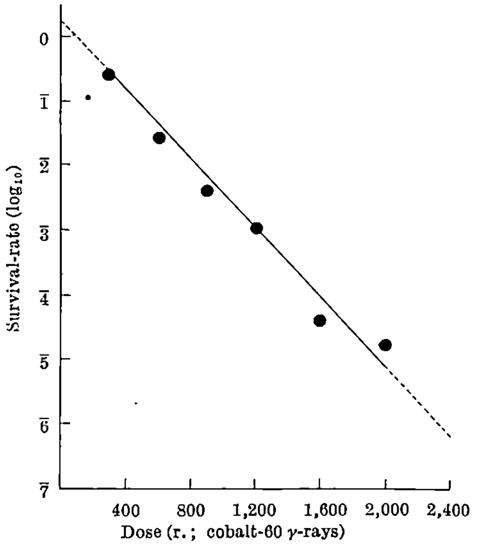

Fig. 1. Variation of log survival-rate and radiation dose for *CBA* leukæmia cells irradiated *in vivo*

The log survival-rate among the leukæmia cells from an irradiated mouse was calculated simply by subtracting the log of the *TD*50 given by the cells from the irradiated mouse from the log of the mean *TD*50 (2 cells) obtained for cells from unirradiated mice. A series of six log survival-rates was determined for cells from individual leukæmic mice which had received whole-body radiation doses between 300 r. and 2,000 r. Within the limits of experimental error, a linear relationship was demonstrated between radiation dose and log survival-rate (Fig. 1).

The curve, drawn by inspection through the points obtained by experiment, indicates a D_0 value (dose of radiation required to reduce the reproductively intact leukæmia cells to 37 per cent) of 162 r. The curve has been confirmed by a series of six further determinations of survival-rates for radiation doses within the range used initially.

In more recent experiments we have shown that the survival-rate for leukæmia cells irradiated *in vivo* in mice breathing 95 per cent oxygen was similar to that for cells from mice breathing 20 per cent oxygen during irradiation. The survival curve for cells irradiated in mice immediately after death, however, under which conditions the cells are assumed to be in an anoxic environment, showed that the anoxic cells were relatively resistant to radiation, approximately 2·3 times the dose of radiation being required for equal survival-rates.

The linear log survival curve obtained for HeLa cells irradiated *in vitro* by Puck and Marcus[3] gave a D_0 value of 96 r. for 230 kV. X-radiation. The D_0 value for leukæmia cells irradiated *in vivo*, after multiplication by the factor 0·75 to allow for the relative biological effectiveness of cobalt-60 gamma-rays compared with 230 kV. X-rays, is 122 r. The comparison indicates that the human cancer cells irradiated *in vitro* are more sensitive to radiation than the mouse leukæmia cells irradiated *in vivo*. However, incomplete studies by us have suggested that the radiosensitivity of mouse leukæmia cells irradiated *in vitro* may approach that of HeLa cells irradiated *in vitro*. The differences observed between the human and mouse cells may, therefore, prove to be due to the different conditions of the cells during irradiation rather than to the difference of species.

The work described is to be reported in detail elsewhere.

Relative Rates of Liver Storage of Pure α-, β-, γ- and δ-Tocopherols in the Growing Chick

Previous work in this laboratory on the storage of vitamin E in growing chicks has shown that only α-tocopherol was present in the liver. Since normal poultry foods often contain a high proportion of non-α-tocopherols[1,2] the ability of the chick to utilize these compounds is of importance. American workers, using the transfer of tocopherol into the egg as an index of utilization[3], found no evidence of the conversion of either γ- or δ-tocopherol to α-tocopherol, but direct measurements of liver storage were not made.

Groups of six birds of a commercial broiler strain (New Hampshire Light Sussex × White Rock) aged six weeks were placed on a purified diet low in vitamin E and depleted for a period of three weeks. Then over a period of five days they were given a series of oral doses of pure α-, β-, γ- or δ-tocopherol in ethanol–water emulsion. Two days after the final dose the birds were killed.

Blood samples were taken and whole livers were removed for tocopherol assay. Lipids were extracted using a modified form of the procedure of Swick and Baumann[4]. Saponification and removal of sterols, carotenoids and vitamin A were carried out using Brown's methods[5], and finally individual tocopherols were separated and identified by means of the two-dimensional paper chromatographic procedure of Green[2].

It was not found possible to identify any individual tocopherol in blood; but all tocopherols were found in liver with the exception of δ-tocopherol. Relative concentrations and recovery rates are given in Table 1.

The relative biological activities for α-, β-, γ- and δ-tocopherols have been quoted by Brown[5] as 100 : 30 : 20 : 1, and Ames[6] as 100 : 6 : 1 : 1 and later[7] as 100 : 33 : 1 : <1. The relative rates of liver storage quoted in Table 1 show some correlation with these values and might offer some explanation for the lower biological activities of non-α-tocopherols and especially of δ-tocopherol.

However, an additional factor in the consideration of biological activity in natural products is that of

Table 1

	Total dose 6 birds (mgm.)	Concentration found in fresh liver (μgm./gm.)	Total recovered in livers (mgm.)	Relative percentage recovery ($\alpha = 100$)
α-Tocopherol	120	1·90 ± 0·19	0·289	100
β-Tocopherol	100	0·76 ± 0·17	0·099	41·2
γ-Tocopherol	120	0·34 ± 0·15	0·054	18·7
δ-Tocopherol	100	Nil	Nil	Nil

availability. Bunnell[8] has shown that the availability of α-tocopherol in lucerne to be only about 30 per cent.

Normal Components of Guinea Pig Serum which may cause Antigens to show an Apparent Anti-complementary Effect

Normal guinea pig serum is the most common source of complement for the complement-fixation test, and may be used fresh or, more commonly, preserved either by freeze-drying or by Richardson's method[1]. Such 'complement' is used in the presence of a great variety of antigens, and the possibility of a reaction between components of this serum other than complement and the antigen is usually either ignored or allowed for as an anti-complementary effect of the antigen acting alone.

To investigate such reactions, normal guinea pig serum was obtained by cardiac puncture from thirty animals, pooled, and preserved by Richardson's method. Following titration this serum was diluted with barbitone buffer solution, so as to contain 12·5 *MHD*50 units (minimal hæmolytic dose giving 50 per cent hæmolysis) per unit volume of 0·5 ml.

1 mgm. 'Zymosan' (Fleischmann Laboratories, Stamford, Conn., U.S.A.)[2] was added to each of two aliquots of 2 ml. of this standardized serum, and these, together with two untreated aliquots, were then incubated at 17° C. for 30 min. One of the aliquots that had been treated with 'Zymosan' was then centrifuged at 3,000 r.p.m. for 3 min. at 0° C. The supernatant fluid was decanted off and recentrifuged to ensure that all traces of the 'Zymosan' had been removed. To the final supernatant fluid 0·5 ml. barbitone buffer solution and a further 1 mgm. 'Zymosan' were added. 0·5 ml. of a 1 : 15 solution of Wassermann antigen (Burroughs Wellcome, alcoholic extract of sheep heart with cholesterol) in barbitone buffer solution was added to one of the aliquots that had not previously been treated with 'Zymosan', and also 0·5 ml. of the barbitone buffer solution to the remaining two aliquots. All four aliquots were then incubated at 37° C. for 15 min.

The amount of complement remaining after the various treatments was determined by titration. The technique used for this titration involved a serial dilution of the four solutions containing the residual complement, with a log dilution factor of 0·125. When 0·5 ml. amounts of each dilution were incubated at 37° C. for 60 min. with 2 ml. of a 0·5 per cent suspension of sheep red cells optimally sensitized with anti-sheep red cell hæmolysin (Burroughs Wellcome), several tubes were obtained within the zone of partial hæmolysis. The degree of hæmolysis in each tube of the titration was estimated by means of an EEL portable colorimeter, and the titre calculated graphically[3].

Pillemer and his co-workers have demonstrated that normal guinea pig serum contains 'Properdin'[4], and this has been shown to combine with components of preparations from a very great variety of plant and animal sources, for example, yeasts ('Zymosan'), bacteria, inulin, dextrans, gastric mucin, viruses, protozoa, trematodes, etc.[5-8]. When such preparations are used as antigens, the complexes so formed are capable of fixing complement by specifically inactivating the third component, at temperatures above 18° C. Below 18° C., however, although the complex is formed, it does not inactivate complement[4]. A factor which will fix complement in the presence of the Wassermann antigen is known to occur in the normal serum of many adult animals, although guinea pig serum has been reputed not to possess this property[9].

Table 1. The Percentage of the Initial Complement remaining following the Various Treatments

Treatment of guinea pig serum		Residual complement as percentage of initial complement (per cent)
Treated with 'Zymosan'	'Zymosan-Properdin' complex removed	46
	'Zymosan-Properdin' complex remains	23
Not treated with 'Zymosan'	Wassermann antigen added	21
	Wassermann antigen not added	63

The results presented in Table 1 show that the amount of complement fixed by the 'Properdin-Zymosan' complex, or by the Wassermann system was markedly greater than the loss of complement activity occurring during the process of incubation, or due to the presence of 'Zymosan' after most of the 'Properdin' has been removed. In the presence of an excess of antigen, this activity will vary with the amount of guinea pig serum present, independently of its complement content, unlike a true anti-complementary effect. Any allowance to be made for this effect, in addition to that made for any anti-complementary action of the antigen, must therefore be determined using the same amount of guinea pig serum as is to be used to provide the complement for the fixation tests in question.

Audio-direction Finding in the Porpoise (*Phocaena phocaena*)

The excellent anatomical work by Reysenbach de Haan[1], the important work on *Tursiops* by Scheville *et al.*[2], and numerous field observations have shown that cetaceans hear extremely well. *Tursiops* appears to possess a sonar system of remarkable quality[3] and one is inclined to believe that such a system may be of general occurrence[4], at any event among the toothed whales.

One of the striking features of hearing in the animal kingdom is the perception of the direction of sound. Experiments with man have shown that the accuracy of perception of direction is based on the difference in time the sound needs to reach both ears. In the case of pure tones and continuous tones the case is somewhat more complicated, phase differences playing a major part at lower frequencies up to about 2,000 c./s., whereas at higher frequencies differences of intensity are of special importance.

Sedee[5] has shown that in man the accuracy with which the direction of sound is determined depends, first, on the angle between this direction and the sagittal plane of the head, and, secondly, on the distance between the ears. Using an artificial head twice as large as normal, he found the threshold angle of direction to be about half its normal value.

Since sound waves travel faster in water than in air, and since the working distance between the bullæ in the porpoise is smaller than that in man, the question arises whether at lower frequencies—where differences of intensity do not play a predominant part—discrimination of direction in cetaceans may be less accurate than that in man, owing to the smaller time-differences involved. In order to get some insight into the matter, experiments were made with a porpoise.

A male porpoise was trained to come to the vicinity of the source of a sound signal by rewarding it with a fish. The underwater signal was produced by a Philips commercial tone-generator and emitted by two barium titanate transducers, one at a time. The transducers were placed at varying distances from each other and the signal was a pure tone, click-free and of short duration (± ⅔ sec.). The signal was given when the animal was on a marked spot at about 18 m. from both transducers. The porpoise could only reach the vicinity of a transducer—which were separated from one another by a net—through a corridor about 12 m. long, and the animal had to choose the right opening at that distance. The enclosure in which the animal was kept had muddy slopes and eel grass on its bottom. It was therefore practically free from disturbing echoes.

It was found that the porpoise chose the right corridor if the mean angle between the transducers—one on the left side and one on the right side of the sagittal plane in front of the animal—was at least 16°. This was when a tone of 6,000 c./s. was used; at 3,500 c./s. the minimum angle is less narrow, at least 22°.

It appears from unpublished observations of Sedee, especially made on our behalf, that in man, when using the same kind of signal (but in the air), the angle in question is about 16° at 1,500 c./s. (giving the same wave-length as 6,000 c./s. in water) and about 24° at 750 c./s. The narrowest angle obtained at 1,500 c./s. was 8–10°, however, apparently half the width of that in the porpoise. As the distance between the bullæ tympani of a porpoise is about half the distance between the ears of man, it appears that, roughly speaking, a porpoise in water and a man in air have about the same degree of acuity of perception of the direction of sound when similar wave-lengths are compared.

Financial and other aid making this investigation possible was obtained from the Netherlands Organization of Pure Research (Z.W.O.), the Laboratory for Comparative Physiology at Utrecht, the Zoological Laboratory of the University of Amsterdam, the Linnaeus Fund, Amsterdam, the Verenigde Toeristen Bedrijven at Harderwijk, the Texel Museum Foundation and several Danish friends. PLANT PHYSIOLOGY

Effect of Light on Maturing Broad Bean Seeds

We have recently shown[1] that the typical development of the etiolated broad bean shoot in darkness is modified by exposing the intact soaked seed to light and that the sensitivity develops at the time when the embryo takes up water. It was suggested that the embryo of the maturing seed may also be sensitive in the same way and that varying conditions of light during maturation may affect the subsequent development of the seedling.

The following experiment was carried out to test whether a light effect on the maturing embryo could be detected in seedlings grown in darkness. Plants were raised in natural light conditions, and some of the pods were enclosed in light-tight bags at an early stage when they were approximately 1 in. long. When mature the seeds were removed from the pods and dried in complete darkness. Seeds from uncovered pods were simultaneously dried in the light for the same period. All seeds were then germinated and grown in darkness; internode-lengths were measured after 13 days.

The mean length of the first internode from seeds matured in darkness (30 seedlings) turned out to be approximately 16 per cent greater than that from the controls (35 seedlings). This difference is significant at the $P = 0{\cdot}05$ level. Clearly the sensitivity develops during the maturation of the seed, and the effect survives a short drying process. The effect of light thus bears some resemblance to the vernalization effect on the embryo of winter rye in that treatment is effective *in the maturing embryo*[2]. The mean length of the first internode from seeds matured in the light does not differ significantly from that of controls grown in the dark from four previous experiments with commercially grown seeds (Table 1). It, in fact, lies above all the means from individual experiments.

Although the experiment was not designed to test this, the results suggest that the effect of light sur-

Table 1. MEAN LENGTH (CM.) OF FIRST INTERNODE OF SEEDLINGS GROWN IN DARKNESS FOR 13 DAYS INCLUDING THE PERIOD OF SOAKING

	Mean length (cm.) of first internode

Seeds matured in light	14·16 (0·623)	13·13 (0·235)
Seeds exposed to 2 hr. light at 24 hr. after the beginning of soaking	—	10·47 (0·251)

Column *A* from the present experiment, column *B* from previous experiments with commercially grown seeds. Figures in brackets are standard errors of the means.

vives the normal long period of inactivity in stored seeds and that the first internode of etiolated seedlings is always partially suppressed by light. It may well be that the higher figure of our controls in the present experiment reflects a reaction to the lower light-intensity in which these seeds were matured as compared with the commercially grown seeds. We hope to verify these inferences by further experiment.

This work has been supported by a grant from the Nuffield Foundation.

Differential Reaction of Saprophytic and Parasitic Soil-inhabiting Fungi to Indoleacetic Acid

INDOLEACETIC acid was shown to be a product of fungus metabolism, when Thimann[1] in 1935 demonstrated that this was the growth-promoting substance (for higher plants) produced by cultures of *Rhizopus suinus*. Later, attempts to reproduce in fungi the growth responses to indoleacetic acid found in higher plants were not successful[2], and interest in this field has been limited. The importance of indoleacetic acid in fungus metabolism has, however, been emphasized by several recent reports, particularly of studies of host–parasite relationships[3–6].

In the course of experiments on the effects of indoleacetic acid on two saprophytic and two plant parasitic soil-inhabiting fungi, growth of the latter was found to be much more readily inhibited than that of the former. *Ophiobolus graminis* Sacc., which causes the well-known 'take-all' disease of wheat and other Gramineae, and *Fomes annosus* Fries, which is a common cause of root and heart rot of conifers, were the two parasites studied. The saprophytes were the two soil fungi *Trichoderma viride* Pers. ex Fries, and *Trichocladium asperum* Harz.

Indoleacetic acid at various concentrations was incorporated in a synthetic liquid medium at *p*H 5·5. The medium was dispensed in 25-ml. aliquots in 200-ml. Erlenmeyer flasks. A mycelium homogenate in 0·25 *M* sodium chloride was used for inoculating the flasks and growth was measured by determining the weight of dried mycelium which developed. Typical data are given in Table 1.

Table 1. EFFECT OF INDOLEACETIC ACID (IAA) ON GROWTH OF FOUR FUNGI

IAA × 10^{-5} *M*	Dry mycelium (mgm.)			
	T. viride	*T. asperum*	*O. graminis*	*F. annosus*
0	180·9	183·7	258·4	84·6
1·0	—	180·0	224·0	46·6
10·0	—	185·5	136·5	0
50·0	169·8	203·8	0	0
100·0	188·1	183·4	0	0
L.S.D. at 1 per cent	—	—	50·4	29·1

Neither *T. viride* nor *T. asperum* was significantly inhibited by concentrations of indoleacetic acid up to 100 × 10^{-5} *M*, while *O. graminis* and *F. annosus* were significantly inhibited at concentrations of 10 and 1 × 10^{-5} *M* respectively and were completely inhibited at higher concentrations. A number of unidentified saprophytic soil fungi behaved similarly to *T. viride* and *T. asperum* in that the higher concentrations of indoleacetic acid did not significantly reduce growth.

These results may have significance for the parasitic or saprophytic development of these fungi. An extension of these findings will be published elsewhere.

Formation of Purple Pigment in *Spirogyra pratensis* Cultures

RECENTLY, investigation of the purple vacuolar pigment of *Zygogonium ericetorum* Kütz.[1] has disclosed that it is formed by an association of ferric ions with a gallo-tannin. Similar algal pigments reported as anthocyanin-like[2] or phycoporphyrin[3] by previous investigators are probably closely related or identical to the iron-tannin of *Zygogonium*.

Most of the algal species which produce purple cell sap are found in bogs or swamps where iron is more likely to be available in rather high concentration. In addition to *Zygogonium*, several other members of the Zygnemataceae produce tannin, and tannin production by *Spirogyra* has been studied[4]. Thus it is possible that other species, not reported to form purple pigment in Nature, might form pigment under appropriate cultural conditions.

In the course of studies of *Spirogyra pratensis* Transeau, one of us (A. A.) observed that, in Waris medium containing iron sequestrene, sub-cultures of the alga in which conjugation was occurring produced purple filaments. Similar sub-cultures in soil-water remained pale green. Although extensive tests were not conducted, the distinctive responses to ammonia and to hydrochloric acid[1] indicated that the pigment which developed in the sub-cultures in Waris medium was similar to that of *Zygogonium ericetorum*.

Afterwards, vegetative filaments of *Spirogyra pratensis* were transferred into flasks of soil-water and of Waris medium. Transfers were made also into small quantitites of soil-water and of Waris medium in watch glasses enclosed within deep Petri dishes. The latter were for the purpose of encouraging conjugation so that we might compare pigment production by sexual and vegetative material. The cultures were kept constantly at about 20° C. under cool white fluorescent lights on a 16-hr. photo-period.

The observations described here were made 35 days later. Material in flasks of soil-water was bright green while that in the flasks of Waris medium showed large patches of purple filaments among green filaments. In the watch glasses filaments in soil-water were pale yellow-green while those in the Waris medium were purple.

Filaments from the Waris medium were examined microscopically. Material in flasks of Waris medium, as well as that in watch glasses of Waris medium, showed some incipient and unsuccessfully completed conjugation. The filaments with purple pigment did not appear to be in a normal physiological state. The chromatophores were still green, but they did not have the regular spiral form typical of healthy cells. The cells were not readily plasmolysed, and the location of the pigment was in doubt. It may have been in the cell sap or perhaps adsorbed to the cell wall. There was no significant difference in the quantity of pigment formed in the material growing in Waris medium in shallow watch glasses and in flasks. Inasmuch as material in watch glasses of soil-water conjugated but did not accumulate purple pigment, it appears that the development of the pigment was not merely correlated with the occurrence of conjugation.

Although we must conclude that it has not been demonstrated that normal healthy cells of *Spirogyra pratensis* form purple pigment, the fact that the alga is capable of forming a large amount of the iron-tannin pigment in certain circumstances is of significance.

It seems now to be indicated that distinction between the algae which form purple pigment and those which do not does not depend upon their ability to synthesize a unique chromagenic substance, but rather upon their ability to tolerate an ecological niche in which iron is available in sufficient quantity to interact with the chromagen or upon their ability to accumulate the iron. There must be differences among species in their ability to produce tannins, of course; but it is obvious that, in *Spirogyra pratensis*, lack of tannin was not the limiting factor.

BIOLOGY

Dissociated Nystagmus in the Rabbit

A PROMINENT feature of all forms of nystagmus is the strict co-ordination of movement of both eyes, brought about by fibre systems which cross from one side to the other. We have observed a curious phenomenon in which both eyes move synchronously but in opposite directions.

A longitudinal channel was cut in the rabbit's skull, extending caudally from the coronary suture to the region of the inferior colliculus and running along the sagittal suture. When a fine knife was guided along this channel, at a depth of 10–12 mm. from the surface of the skull, a spontaneous nystagmus, starting with a slow adduction of both eyeballs, was observed in 60 per cent of our experiments. During the rapid phase, the right eye moved to the right and the left one to the left side, that is, simultaneous contraction of both external rectus muscles occurred. The rhythm of this nystagmus was slow and irregular, but exact synchronicity was always preserved, as shown in the nystagmogram (Fig. 1).

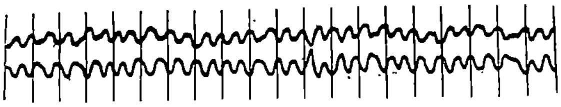

Fig. 1. Nystagmogram of dissociated nystagmus. Upper curve, left eye; lower curve, right eye. Excursions upwards indicate movement of eyeballs to right, downwards to left. Vertical lines, time (sec.). Note irregularity and synchronicity of the dissociated nystagmus

The dissociated nystagmus lasted only for a brief period (some seconds, up to several minutes). This suggests that the acute lesion was responsible for the phenomenon. Rotation of the rabbit during the spontaneous movements, or electrical stimulation of the 'nystagmogenic centre' in the midbrain[1] produced the normal response, which superseded the dissociated nystagmus. It is thus evident that cross-connexions between left and right are still available, although the decussation, occurring in the posterior commissure[2], has been divided. This conclusion is supported by the fact that application of deeper cuts abolishes the dissociated nystagmus as well as the response to labyrinthine or central stimulation.

A full description of these experiments will be published in the *American Journal of Physiology*.

Strain Differentiation in a Root-infecting Fungus

IN various fields of mycology it has long been realized that, for certain purposes, the orthodox descriptive method of systematic classification is by no means adequate. Fungal strains grouped together on the bais of similar physiological reactions have been found to cut right across species of diverse taxonomic affinities, and it appears that in such disciplines as, for example, clinical medicine, agriculture, and forest pathology, the strain rather than the species is frequently of importance.

While studying the influence of certain root-infecting mycelia on the development of forest tree seedlings, unequal growth effects on the young plants were observed which strongly suggested different strains of the same fungal species as being responsible for the dissimilar performances of the seedlings. Confirmation of such strain differentiation was obtained

by pure culture tests of various isolates of the fungal species under observation. The species generally designated *Boletus scaber* Bull. (*Leccinum scabrum* S. F. Gray; *Krombholzia scabra* [Fr.] Karst.) was used as one of the main objects for these pure-culture tests, since two isolates of this fungus had been observed to influence the growth of young birch trees unequally[1]. Altogether, seven isolates of *B. scaber* were submitted to the tests. Two of the mycelia, (1) and (2), were derived from sporophores collected from heathland soils; another, (3), came from a sporophore on a moorland soil; (4), (5) and (6) were isolated (by M. E. Parry) from fruit-bodies of the species appearing in deciduous woods. The Centraalbureau voor Schimmelcultures in Baarn, Holland, kindly supplied isolate (7), ex Sweden.

These mycelia were tested along the following lines: (*a*) growth reactions on various broadleaf-, conifer-, and heather-litters (steam-sterilized); (*b*) gum guaiac test; (*c*) Bavendamm test (using 0·1–0·3 per cent tannic acid); (*d*) growth and colour reaction on dextrose tryptone agar with brom-cresol purple ('D.T.A.' medium, supplied by Oxoid, code Nos. *G.M.* 75 and 76); and (*e*) growth and colour reaction on a tryptophan medium (using 0·1 per cent tryptophan as the sole or the additional source of nitrogen).

The results listed in Table 1 show that, on the whole, isolates (1) and (2) behave similarly. They both make good growth on a wide range of litters and give a negative reaction for phenoloxidase in the guaiac and Bavendamm tests. However, isolate (1) differs from (2) in its ability to discolour the 'D.T.A.' medium (due to a change in *p*H), also by producing a change in colour of the tryptophan medium, the change ranging from pink to cherry red, apparently caused by a metabolite derived from the tryptophan.

No interpretation of the reactions recorded in Table 1 can be put forward at this stage of the investigation. This communication is merely concerned with demonstrating the fact that the 'species' *B. scaber* does not show a uniform physiological spectrum as reflected in certain pure culture tests, which is in agreement with strain differentiation expressed in unequal effects on the growth of seedlings following inoculation of isolates (1) and (3) as reported earlier[1]. The influence of other strains of the species on the development of young trees has not been fully recorded yet.

In view of the fact that isolates (1) and (2), both from sporophores on heathland soil, react, in certain respects, similarly (Table 1) and contrast with the behaviour of the other mycelia tested, one feels tempted to suggest that differences in ecological origin might be responsible for the strain differentiation recorded. However, in order to obtain definite evidence that such a relationship exists, isolates of *B. scaber* from an additional number of localities have to be analysed and, among the ecological factors taken into account for the selection of sporophores, the tree species occurring in the neighbourhood of the fungus should be considered.

Forest Seedlings and Mycorrhiza Development on Fly Ash

The industrial ash which is a serious agricultural problem in developed countries is an even greater danger to forest stands. This is because the deposited layer is incorporated into the mineral soil in agricultural land, whereas in forests near industrial enterprises it is constantly increasing.

Table 1

	P_2O_5	K_2O	CaO	MgO
Mgm./1,000 gm. soil in 1 per cent citric acid	373·7	93·1	2,441·6	2,008·5
Percentage dry weight	0·39	0·08	1·36	0·67

Observations[1,2] on the effects of fly ash on vegetation and the discovery of toxic elements in it led us to study its effect on the forest stands. The stands were near a coal power plant in Central Bohemia using black coal. The average amounts of the main plant nutrients in the soil is given in Table 1. The *p*H of the soil was 6·36. Spectral analysis gave the following further elements: silicon, aluminium, manganese, iron, boron, tin, copper, barium, titanium, vanadium and beryllium. The presence of elements with proved toxicity in the fly ash is evident. For this reason further attention was directed to (1) the analysis of vegetation on plots covered with ash; (2) vegetation trials with seeds of forest tree species; (3) the development of mycorrhiza on seedlings from the ash layer. On plots with a heavy layer of ash acidophil vegetation (*Vaccinium myrtillus, Deschampsia flexuosa,* acid mosses) tend to give way to species which prefer a less acidic environment (*Fragaria vesca, Brachypodium sylvaticum, Melica nutans*) and which confirm a considerably rich layer of ash. Fly ash seems to have little effect, however, on the total number of species. Similarly, laboratory tests on Norway spruce and Scots pine showed that they developed identically on ash and on the natural substrate, namely, forest humus. An outstanding characteristic of the plots with a heavy layer of ash is the vigorous regeneration in numerous species, notably broad-leaved trees. As in the previous investigations the ash did not appear to have an unfavourable effect, we therefore directed our attention to naturally sown seedlings, particularly with regard to the development of the mycorrhiza on their roots. Mycorrhiza, as one of the connecting links of the plant with the soil, by its susceptibility to various toxic substances[3], can give some indication of the environment in which the roots are living.

Investigations were carried out on several species; the results were as follow:

Mountain ash: endotrophic mycorrhiza with a tendency to parasitism.

Maple: without evident endotrophism; autotrophic nutrition.

Birch: typical ectotrophic mycorrhiza with strong fungus coat; partially automycotrophic nutrition.

Summer oak: typical ectotrophic mycorrhiza with fungus mantle and Hartig net on most roots. Automycotrophic nutrition prevails.

Larch (*L. decidua*): most seedlings with incomplete ectotrophic mycorrhiza; individually endotrophic mycorrhiza. Automycotrophic nutrition prevails on all seedlings.

Scots pine: on most roots only ectotrophic mycorrhiza; automycotrophic nutrition prevails.

Norway spruce: all roots with ectotrophic mycorrhiza; automycotrophic nutrition.

Hazel: well-established ectotrophic mycorrhiza.

All three stages of this work (analysis of ground vegetation in forest stands; laboratory vegetation trials; and analysis of lateral nutritive roots of natural regeneration) agree. The fly ash from black coal, although it contains apparently unfavourable elements, does not have harmful effects on forest tree species or on herbaceous vegetation. This conclusion cannot be generalized: the effect of fly ash on vegetation has to be investigated in each individual case. It is interesting that the mycorrhiza appear quite normal in an abnormal environment.

Analysis of Mast Cells by means of Polarization Microscopy

It has already been established that mast cells contain heparin[1], hyaluronic acid[2], histamine and 5-hydroxytryptamine[3].

Mast cells are an inhibiting factor in the clotting of blood. They are an active factor in fibrinolysis. They decompose the structure of lipids, and bind and set free histamine and 5-hydroxytryptamine. They have a cytostatic effect. They produce the ground substance of connective tissue. They exert an antitryptic effect, and enter into the metabolism of sulphur. In spite of this little is known about the structure of the protoplasm between the granules of mast cells. The problem is how to study this protoplasm, to follow its development and to investigate the connexion between the multifarious functions of the mast cells and this protoplasm. The latter can be investigated if we change it into an anisotropic substance. We have searched for dyes which stain the granules of the mast cells well and at the same time produce anisotropy in the components of their cells, and have found that pyronin *G*, toluidine blue and neutral red (Grübler) dissolved in an acid medium (1 per thousand in *N*/10 hydrochloric acid) produce anisotropy in the intergranular protoplasm of the mast cells. The birefringence cannot be extinguished by imbibition (Fig. 1).

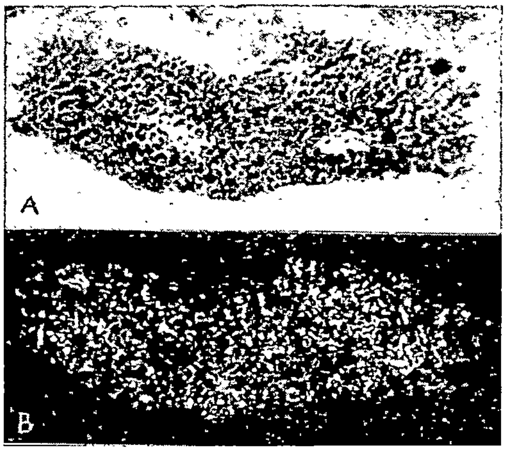

Fig. 1. Mast cell from the connective tissue of a rat. Without fixation. (*A*) Dye: 1 per mille neutral red solved in *N*/10 hydrochloric acid. (*B*) The same examined in polarized light. (× 600)

Preparations of membranes from the subcutaneous loose connective tissue of albino rats were used, and also rat mesentery embedded in paraffin. They were fixed by heat, chloroform – methyl alcohol or basic lead acetate. Some were stained without fixation, after drying at ordinary temperature. We did not find any difference as regards anisotropy between the mast cells in the fixed and non-fixed preparations,

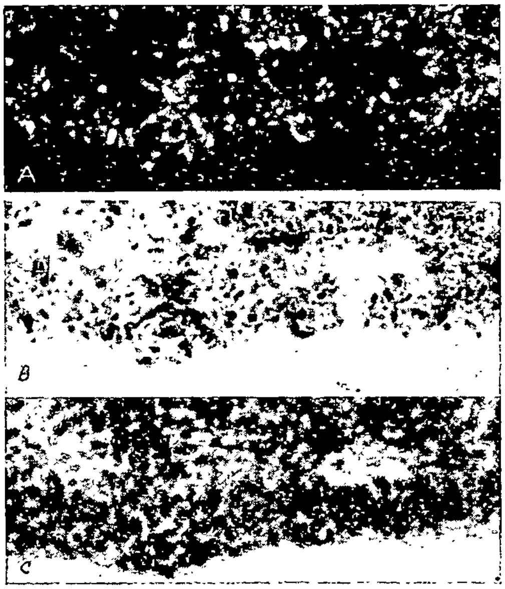

Fig. 2. Part of the cell shown in Fig. 1. (*A*) Examined in polarized light. (*B*) Contact-copy of the negative of *A*. (*C*) The same examined in normal light. (× 1,500). Note that the location of anisotropic substance in *B* is not the same as in *C*, proving that the anisotropic substance is not in the granules

or between those in the membrane preparations and those in sections.

At first it seemed that the granules of the mast cells became anisotropic; but closer analysis, however, disclosed that it was the intergranulary substance that became birefringent (Fig. 2).

The anisotropic substance is digested by ribonuclease, hyaluronidase, pepsin and trypsin. After extraction by Keilig's method[4], by which all fat-like substances are removed, birefringence is increased. This shows that the intergranulary substance is surrounded by a layer of fat-like substances which inhibit the diffusion of enzymes. But these enzymes do not digest the anisotropic substrate even after extraction by Keilig's method. Anisotropy can also be produced by using a hydrochloric acid – alcohol solution of dye. Anisotropy develops even when staining is carried out at a temperature of 80° C.

Anisotropy is prevented if saturated aqueous urea solution or 1 per cent protamine sulphate solution is used.

The dyes producing birefringence have the common property of two different poles (haptofore groups), one of which is lipophile, whereas the other is salt-producing[5]. We presume therefore that there is some complex lipoprotein material present in the intergranulary substance which possesses partly acid and partly alkyl side-chains. The side-chains of both types are oriented. The salt-producing group plays a decisive part in the development of anisotropy.

The anisotropic substance of the mast cells can be clearly followed in the connective tissue even after their disintegration.

PATHOLOGY

Oxygen Exposure and Brain Damage

IN human premature infants, prolonged exposure to an oxygen concentration above 30–40 per cent in an incubator tends to produce retinal damage[1] (retrolental fibroplasia). A similar disease has been produced experimentally by oxygen exposure of newborn mice, rats, kittens and other animals, which are relatively immature at birth as compared with full-term human babies[2-4]. With the exception of pulmonary injury[5], no other pathological alterations have been reported after oxygen exposure of premature infants. As the brain, like the retina, develops considerably after birth, special attention was paid to the influence of oxygen exposure on the maturation of the brain. No characteristic brain injury has been found in children exposed to oxygen, though neurologic and mental defects are more common in children with retrolental fibroplasia than in other prematurely born children[6]. No brain damage in animals after similar treatment has hitherto been observed[3,4].

Definite alterations in the post-natal development of the cerebral cortex in mice after oxygen exposure are reported in this communication. Newborn mice were kept in 90–100 per cent oxygen continuously for 5–30 days after birth. Other mice were kept in oxygen for 5–15 days, after which they were transferred to air for 5–60 days before use. Still others, not exposed to oxygen, served as controls. More than 500 mice were used.

The relative amounts of cortical capillaries were measured on frozen sections after intracardial injection of indian ink. Continuous exposure to oxygen reduced the mass of vessels per standard area of section, the decrease amounting to 20 per cent at 15 and 20 days, in the visual as well as the motor cortex. Exposure to oxygen for 5, 10 or 15 days, followed by normal conditions, resulted in an intensified growth of the cortical vessels, in the visual and the motor areas. After 5 days in oxygen and then 15 days in air, a vascular hyperplasia was found, the relative amount of vessels exceeding that of the controls by some 10 per cent.

These alterations in cerebral vascularization are similar to the early stages in the pathogenesis of retrolental fibroplasia and of retinal damage induced by oxygen in experimental animals. In oxygen, the post-natal vascularization of the retina is suppressed. After transfer from oxygen to air, a pathological enhanced neo-vascularization of the retina takes place. Thus, similar changes occur in the cortex cerebri, though no qualitative pathological changes are seen.

In the eye, permanent retinal atrophia is often observed in adults after exposure to oxygen of newborn mice. Similarly, in cortex cerebri, the initial vascular hyperplasia after transfer from oxygen to air was followed by a slight reduction of the relative amount of cortical vessels. This vascular hypoplasia was, however, only present in the visual cortex, not in the motor cortex. It might be supposed that the vascular hypoplasia in the visual cortex depended on retinal damage and thus constituted a transneuronal alteration, due to disturbed visual function.

A second series of experiments was made in order to test this hypothesis. Growing mice were kept in complete darkness for 20 and 30 days, and the vascularity of the cortex was measured. A decrease in capillary amounts was observed, and this decrease was manifest in the visual cortex only, not in the olfactory area.

Besides studies on the vascularization of cortex cerebri, quantitative studies on the growth of the cortical cell nuclei and on the growth of internuclear material ('neuropil') were performed. Continuous exposure to oxygen for 10 days resulted in cortical intracellular œdema, indicated by nuclear swelling and an increase in the amount of neuropil per nucleus. Such cortical œdema may be of importance in the vascular hypoplasia, causing a capillary compression (as was suggested by Ashton[7] regarding similar reactions in the retina of animals exposed to oxygen). After the cortical swelling, prolonged exposure to oxygen caused a decrease in nuclear size and in neuropil growth. These alterations in the post-natal maturation of the brain cortex were observed in both the visual and the olfactory area. In contrast to the general effects on the cortex cerebri of exposure to oxygen, there was retardation of neuronal growth and of neuropil increase in the visual cortex only, not in the olfactory cortex, in animals kept in the dark for 20–30 days after birth.

Thus, exposure of growing mice to concentrated oxygen suppresses the post-natal maturation of cortex cerebri by both direct and indirect action (through retinal damage).

The present investigations will be published in full elsewhere.

Role of the Thymus in Murine Leukæmia

LYMPHOCYTIC neoplasms with characteristic thymic involvement occur spontaneously with high frequency in certain strains of mice[1], and in other strains following X-irradiation[2], chemical carcinogens[3] or the inoculation at birth of cell-free extracts of leukæmic tissue from high leukæmic strain mice[4]. Total thymectomy has been shown to reduce markedly the incidence of the disease, either spontaneous[1] or induced[2,3]. No report has yet appeared as to the effect of subsequent thymectomy on the occurrence of the disease in mice inoculated at birth with leukæmia extracts. Harris[5] has, however, an interesting theory which suggests that non-cellular leukæmic-inducing extracts might be capable of replacing thymic influence. Latarjet *et al.*[6] and Furth *et al.*[7] have shown that inoculation of *Ak* leukæmic cell-free extracts into newborn *Ak* mice accelerates the development of leukæmia. The effect of thymectomy on this acceleration has been investigated and reported here.

Newborn Ak_i mice, from a colony maintained by strict sib-matings in these laboratories since 1945, were divided into three approximately equal groups, each litter being divided between the three groups. The control group had their tails cut off for identification purposes but received no further treatment apart from an intraperitoneal injection of saline. Mice in the other two groups were inoculated within 16 hr. of birth with Ak_i leukæmic cell-free filtrates prepared according to Gross's method[4]. Extracts were made from either leukæmic thymus only, or leukæmic lymph nodes only. At 3–4 weeks of age about half the inoculated mice were thymectomized, the thymus being sucked out of the thorax through an incision in the neck. The three groups were caged side by side and maintained on ordinary laboratory diet.

The results are given in Table 1. Almost all the inoculated mice which were not thymectomized succumbed to leukæmia between 3 and 6 months of age. The majority of the untreated control mice contracted the disease but not until after the seventh month. None of the mice inoculated with either leukæmic thymus or leukæmic lymph node extracts at birth and afterwards thymectomized has yet succumbed to leukæmia. In contrast to the recent findings of Furth[8] no tumour other than leukæmia has yet been seen in any mice of the present series.

The results clearly show that in *Ak* mice inoculated at birth with cell-free extracts of leukæmic tissues, thymectomy suppressed the subsequent appearance of leukæmia. There can be little doubt as to the cell-free nature of the present extracts of leukæmic tissues for no leukæmia appeared in the thymectomized and inoculated animals, whereas it can easily be shown that thymectomy does not affect the transmission of leukæmia by cell graft. The effect of thymectomy on the incidence of leukæmia in low-leukæmic strain *C3H* mice inoculated at birth with *Ak* leukæmic cell-free extracts is under investigation and will be reported later.

Table 1. INCIDENCE OF LEUKÆMIA IN Ak_i MICE INJECTED AT BIRTH WITH FILTRATES FROM Ak_i LEUKÆMIC TISSUES

Treatment	Total No. of mice	Age in days at time of diagnosis					Leukæmia incidence	
		60–90	91–150	151–180	181–210	211–300	No.	Per cent
Injected at birth	29	1	18	5	2	1	27	93
Injected at birth, thymectomized	21	0	0	0	0	0	0	0
Control	34	0	0	1	3	27	31	91

I am indebted to a scholarship from the University of Queensland, Brisbane, Australia, and to Profs. A. Haddow and P. C. Koller and Dr. R. J. C. Harris for their interest. Plaque Production with Yellow Fever and Related Arthropod-borne Viruses

WHEN a monolayer of chick fibroblasts is exposed to infection with a suitable dilution of Western Equine Encephalomyelitis virus and afterwards incubated under a layer of agar containing cell nutrients, areas of cell destruction or 'plaques' are produced; these were shown by Dulbecco[1] to result from infection by single virus particles. The plaque technique has since been applied to a number of other viruses; but the presence of cell destruction or a cytopathic effect is normally considered to be a prerequisite for the success of the technique.

Among the arthropod-borne viruses, cytopathic changes are generally strong with group *A* viruses, such as *WEE*, but are weak or absent with group *B* viruses[2]. The demonstration by Bhatt and Work[3] that West Nile virus (which falls within the group *B*) was readily adapted to produce a cytopathic effect in tube cultures of chick embryo fibroblasts suggested that this virus might be titrated in monolayers of these cells. It was observed that early passage-levels of West Nile virus (Egypt 101 strain) which failed to produce a definite cytopathic effect in tube cultures of chick fibroblasts nevertheless yielded plaques when introduced on to chick fibroblast monolayers[4]. This observation suggested that other viruses which multiply in chick fibroblasts without producing a definite cytopathic effect might, under suitable conditions, produce plaques.

Because of its importance in the group, attention was first directed to yellow fever virus. The 17*D* strain of this virus was adapted to chick embryos by Theiler and Smith[5]. Tube cultures of chick fibroblasts support the growth of virus, but show no definite cytopathic changes. When chick fibroblast monolayers are infected with 17*D* virus under the conditions of the plaque technique, a change in the staining properties of virus-infected cells can be detected on or after the fourth day, with the development of discrete plaques 2–3 mm. in diameter. These are readily counted on the fifth or sixth day as whitish areas against a background of cells stained pink with neutral red.

In early experiments some difficulty was experienced in maintaining chick cells in a healthy state under agar for the 5 or 6 days necessary for plaque production. The technique finally adopted was to grow chick fibroblasts in a medium containing 5 per cent calf serum, 5 per cent lactalbumin hydrolysate (5 gm./100 ml.) and 90 per cent Gey's solution[6] incorporating 5 per cent sodium bicarbonate (2·25 gm./100 ml.). Overnight incubation at 37° C. of $40–50 \times 10^6$ cells in 5 ml. of medium in an atmosphere of 5 per cent carbon dioxide gave dense confluent monolayers. These were exposed to dilutions of virus in 10 per cent calf serum in Gey's solution without bicarbonate for periods of 1–4 hr. at 37° C. After removal of unadsorbed virus the plates were overlaid with a medium made by mixing equal parts of 2·0 per cent agar in distilled water and the following: Gey's solution *A* (ten times concentrated) 20 per cent, Gey's solution *B* 10 per cent, *tris* (hydroxymethyl) aminomethane 0·2 *M* *p*H 7·6 10 per cent, lactalbumin hydrolysate (5 gm./100 ml.) 10 per cent, calf serum 10 per cent, neutral red (1 : 1,000) 10 per cent, distilled water 30 per cent. Under these conditions chick cells remain healthy for seven or more days when incubated in a well-humidified incubator without added carbon dioxide. A preparation of 17*D* virus which contained 8×10^6 *LD*50 per ml. when titrated intracerebrally in mice has given titres ranging from $1{\cdot}4 \times 10^6$ to $4{\cdot}5 \times 10^6$ plaque-forming units per ml. according to the conditions of the test. Details of this work and of a technique for determining yellow fever neutralizing antibody will be published elsewhere[7].

The modified plaque technique was next applied to a representative selection of other group *B* arthropod-borne viruses, including the French neurotropic strain of yellow fever virus, Uganda *S*, West Nile, Wesselsbron, Japanese *B* and Louping ill viruses. West Nile, Uganda *S*, Japanese *B* and Wesselsbron viruses produced plaques which were readily visible on the second or third day and increased to 5 mm. in diameter. Zika virus resembled 17*D* in producing smaller plaques which were not visible until the fourth or fifth day. Somewhat unexpectedly, neurotropic yellow fever virus which has been maintained by serial passage in mouse brains and has never been passaged in chick tissues gave plaques which were larger and more distinct than those produced by egg-adapted 17*D* virus. Louping ill virus produced plaques which were indefinite until the seventh day. At this time they measured 2–3 mm. in diameter and were countable though less readily than with the other viruses.

There can be little doubt that the cells which make up a plaque produced by infection by *WEE* virus are in fact dead. The plaques produced by yellow fever virus have less distinct margins and frequently include a number of cells which retain the neutral red stain towards the centre of the plaque. Whether cells which lose the property of staining with neutral red are in fact dead or are in a state which is reversible and from which they normally recover in liquid media is uncertain. However, it is clear that the conditions of the plaque technique produce a change in the staining properties of virus-infected cells which represents a form of cytopathic effect which is considerably more readily detected than that normally observed by direct microscopy.

BACTERIOLOGY

Bacteriophage Enrichment in a Liquid Two-Phase System with Subsequent Treatment with 'Freon' 113

THE possibility of concentrating protein molecules in one of the phases in a liquid two-phase system of polymers has been investigated by Albertsson[1,2], who showed that the distribution coefficient can be related to the size of the molecules in accordance with the Brønsted[3] formula. Albertsson and Frick[4] have shown that in a dextran–methylcellulose system this relation holds for particles up to the size of phages, the upper limit at present being the size, or rather the surface area of T_2 phage. The concentration of T_2 in the bottom dextran-rich phase will be 400 times higher than in the methylcellulose-rich top phase if the two phases are allowed to separate for 48 hr. in the cold.

When phages are grown in litre quantities of substrate, it is convenient to diminish this amount to volumes more easily handled in a usual high-speed centrifuge. Essential drawbacks of the centrifugation technique (see, for example, ref. 5) are that a portion of the phages in a pellet will be broken and destroyed by the centrifugal force and that the resuspended particles will be somewhat aggregated. A more homogeneous high-titre suspension can probably be obtained directly by the two-phase liquid enrichment technique. The necessary purification of the suspension for the removal of bacterial debris can be obtained by treatment with a commercially available fluorocarbon, 'Freon' 113.

The procedure is as follows. *Escherichia coli*, strain *B*, is grown in 2,000 ml. of a well-defined medium, Friedlein buffer[6]. The growth takes place in a container of stainless steel fitted with an outlet quite near the bottom and with a device for good aeration. The container is thermostatted at 37° C.

When the titre of *E. coli* is about 10^8, judged from absorption at 600 mμ in the Beckman *B* spectrophotometer, enough phages are added to bring the phage titre well up to 10^6. 5–6 hr. later the medium becomes fairly clear, and the phage titre is $2–5 \times 10^{10}$. The weight of the substrate is now adjusted back to 2,000 gm. by adding distilled water, compensating for evaporation losses. The two polymers methylcellulose ('Methocel' U.S.P. 4,000 c.p.s. from Dow Chemical Co., U.S.A.) and dextran (intrinsic viscosity 0·68 from AB Pharmacia, Sweden) are added. 601 gm. of 2 per cent methylcellulose and 131 gm. of 10 per cent dextran are weighed into the container and the contents mixed thoroughly by whirling. The container is put in the cold room (+6° C.) in an inclined position, the above-mentioned outlet being at the lowest point. After 36–48 hr., the dextran-rich bottom phase which has now formed is drawn off through a capillary stopcock. The top phase is quite clear in appearance, whereas the bottom phase is turbid. As the viscosity of the top phase is much higher, the passage of the boundary through the outlet will also show a decrease in the dropping speed from the stopcock to about one-half.

The bottom phase will have a volume of about 200 ml. containing 96–97 per cent of all phages and having a titre of $2–5 \times 10^{11}$, that is, about ten-fold increase in titre. The loss is due to the 3–4 per cent remaining in the upper phase. Besides this loss, there is a loss of about 10 per cent of the total compared with the total amount of phage at the time of the addition of polymers 48 hr. earlier.

The phage suspension is treated with one-third its volume of 'Freon' 113 ($CCl_2F–CClF_2$) in a Waring blendor cooled with ice[7]. The blendor is operated at high speed for 4 × 15 sec. with intervening pauses of 30 sec. After this treatment, the suspension is centrifuged at 800*g* for 10 min. The layer of denatured protein and 'Freon' will form a semi-solid pellet, and the supernatant can easily be decanted. The procedure is then repeated until after 6–7 treatments only a thin layer is formed between the 'Freon' and the dextran–water phases. In the 4–5 last treatments, the Waring blendor is operated for 4 × 25 sec.

The phages appear to withstand the 'Freon' treatment well. For six treatments the following titres were found: 1·8, 2·0, 1·6, 1·7, 1·9, $2·0 \times 10^{11}$. An increase after the first treatment, especially for very opaque suspensions up to 30 per cent, is often noted. It is, however, also necessary to be careful to avoid coprecipitation of phages with the denatured protein and the methylcellulose. The treatment with 'Freon' precipitates the methylcellulose, but not the dextran. (The loss in volume can be kept to 5 per cent.)

The dextran seems to have a strong protective effect, as 'Freon' treatment of phages suspended in only Friedlein buffer will result in a drop in titre of 10^3 each time. Phage suspended in full media (Difco nutrient broth) will be fully protected, but the medium will change since the treatment with 'Freon' gives a heavy precipitate in unused fresh media.

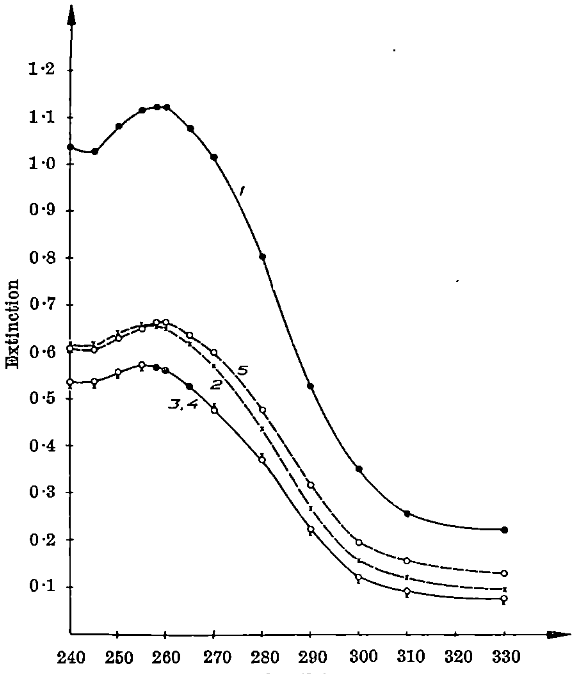

Fig. 1. Absorption of a T_2 preparation treated with 'Freon' 113. Curve 1, untreated phage suspension in dextran-rich bottom phase (titre, $3·4 \times 10^{11}$); curve 2, same suspension after one treatment with 'Freon' (titre, 2×10^{11}); curves 3 and 4, same suspension after four and six treatments with 'Freon' (titre, 2×10^{11}; curve 5, the values of curve 1 recalculated to the same, in this case lower, titre of curve 2. The result shows that the loss of titre corresponds to a loss in material through precipitation (probably co-precipitation). All absorption measurements on suspension, twenty times diluted with Friedlein buffer, against the same buffer

The effect of the treatment with 'Freon' on the ultra-violet spectrum of the suspension is shown in Fig. 1 and Table 1. For further purification, smaller fragments of protein can be removed by dialysis overnight against buffer. (Longer dialysis will cause losses.) If, for special purposes, it is necessary to free a suspension from all free nucleotides, this can be done by shaking with a small amount of calcium hydroxylapatite[9,10]. This operation will, however, cause some slight loss in titre. The quotients of the absorption value at 260 mμ and 280 mμ reported in Table 1 indicate a decrease in protein after treatment with 'Freon' and dialysis, and a decrease in nucleotides due to adsorption on hydroxylapatite.

To compensate for possible losses in the last operation or after sterile filtration, or to double the titre anywhere in the described procedure, 1 part of 2 per cent methylcellulose is added to 1 part of the

Table 1. QUOTIENTS OF ULTRA-VIOLET ABSORPTION AT 260 AND 280 Mμ FOR A T_2 PHAGE SUSPENSION AFTER DIFFERENT TREATMENTS

	$\frac{OD\ 260}{OD\ 280}$	$\frac{OD\ 260}{OD\ 280}$ (corrected values)
Untreated suspension	1·39	1·35
1 treatment with 'Freon'	1·50	1·61
6 treatments with 'Freon'	1·53	1·63
+ dialysis	1·62	1·73
+ treatment with calcium hydroxylapatite	1·60	1·68

The values in column 2 are given after correction for background absorption calculated from ultra-violet absorption values between 330 and 370 mμ (ref. 8).

bottom phase. After shaking, the two solutions are allowed to separate in the cold for 48 hr. The new dextran-rich bottom phase will be of about half the original volume, and accordingly will have a double titre. (All phage titres are determined with the agar layer technique[6].)

This work has been financially supported by the Swedish Technical and Natural Science Research Councils and the U.S. Department of Army through its European Office, under contract number *DA*-91-508-*EUC*-287.

Chloramphenicol and the Survival of Airborne Bacteria

In recent years the large increase of staphylococcal infections in hospitals has resulted in much research into the sanitation and disinfection of hospital wards; but little work appears to have been conducted on the airborne survival of the causative agents. In the course of studies on the viability of airborne bacteria, certain observations were made which may, in part, explain the spread of these cells, especially the antibiotic-resistant strains.

Cells from each of a 24-hr. broth culture of *Staphylococcus albus*, *Serratia marcescens* and *Escherichia coli* were harvested by centrifugation, washed once and resuspended in distilled water. These suspensions were then aerosolized, by means of a Collison spray[1] into a stainless-steel rotating drum[2] of 1,100-litre capacity. Samples were collected in liquid impingers immediately after aerosolization and at subsequent hourly intervals up to 5 hr. The initial concentration in the drum was approximately 1×10^6 cells/l. of air. Loss due to physical fall-out was calculated using a modification of the radioactive tracer technique described by Harper *et al.*[3].

Viable decay-rates were calculated for the 5-hr. air suspension from the equation:

$$K = 1/t \times \ln N_0/N_t$$

where t is time of air suspension in minutes, N_0 is initial concentration of viable cells/l. of air, and N_t is concentration of cells/l. of air at time t.

The decay-rates of the antibiotic-sensitive cells were compared with (*a*) those of a resistant strain obtained from the parent strain by growth on chloramphenicol gradient plates and (*b*) with those of sensitive cells aerosolized from a suspension in a solution of 0·25 per cent chloramphenicol. In the course of study, cells were aerosolized from solutions of other bacteriostatic substances and vitamins and the results of two of these with chloramphenicol are shown in Table 1.

Table 1. Death-Rates of Some Bacteria Aerosolized from Various Media

Organism		Suspending medium			
		Water	Chloramphenicol (0·25 per cent)*	*o*-Amino phenol (0·5 per cent)*	Inositol (6·0 per cent)*
Staphylococcus albus	*S*	0·007	0·002	0·001	0·001
	R	0·002	0·003	0·002	0·002
Serratia marcescens	*S*	0·034	0·010	0·007	0·001
	R	0·012	0·008	0·008	0·002
Escherichia coli	*S*	0·029	0·013	0·006	0·001
	R	0·011	0·010	0·007	0·002

Relative humidity, 30–32 per cent; temperature, 25° C. *S*, sensitive to chloramphenicol; *R*, resistant to chloramphenicol.

* The concentrations of added compounds shown are those found to give optimal aerosol survival.

It can be seen that the *Staphylococci* are far more resistant to aerosol death than the two other genera, and it would appear that resistance to chloramphenicol affords considerable stability to the cells. More surprising, however, was the suggestion that a like stability could be afforded the cells by suspension in the antibiotic prior to aerosolization, and that aminophenolic compounds were also protective. Far greater stability was afforded the cells by inositol, but considerably higher concentrations were required. In the presence of chloramphenicol, however, the quantity of inositol could be reduced by half without decreasing the stability of the cells. Thus there appeared a synergistic action between the drug and the vitamin. The observed increase in survival of cells by these compounds was found to depend on the relative humidity of the air, chloramphenicol affording greater protection to the cells at high relative humidity while inositol was more effective at low relative humidity-levels.

In more recent experiments other bacteriostatic drugs, such as some of the sulpha drugs, and *cyclo*hexane substituted with hydroxyl- or amino-groups have been found to enhance bacterial aerosol survival, and the position of the substituents on the ring appears important. As a result of this work a hypothesis has been formulated that airborne cells die as a direct result of the loss of bonded water from their protein with the subsequent collapse of protein structure. It is felt (*a*) that the compounds affording increased stability to the cells are able to preserve protein structure by taking the place of water molecules during desiccation, and (*b*) that the type of bonding between protein-water and protein-compound is weak, reversible and dependent on the relative concentrations of compound and water. It is thus possible that chloramphenicol enhances bacterial aerosol survival by the same mechanism as it inhibits protein synthesis, that is, it takes the place of water molecules or blocks the water-bonding sites of the protein but does not destroy its structure, thus enzymatic action and synthesis is prevented. When, however, the drug is diluted by body fluids or water the reverse reaction occurs, water molecules displace chloramphenicol molecules and cellular metabolism is resumed.

The fact that bacteriostasis, by several organic compounds, normally used in chemotherapy and disinfection, may preserve airborne cells might, in part, explain why some measures of sanitation have failed in hospitals.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, April 13

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, London, W.C.2), at 6 p.m. Discussion on "The Function and Content of an Electric Theory Course" opened by Mr. F. E. Rogers.

Royal Geographical Society (at 1 Kensington Gore, London, S.W.7), at 8.30 p.m.—Lieutenant N. C. Flemming: "Last Summer's Cambridge Expedition to Explore the Submerged Ruins of an Ancient Port and City Off the Libyan Coast".

Tuesday, April 14

Institution of British Agricultural Engineers (at 6 Buckingham Gate, London, S.W.1), at 2.15 p.m.—Mr. P. H. Bailey: "The Measurement of Crop Drier Performance".

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.1), at 5 p.m.—Scientific Papers.

Institution of Mechanical Engineers, Automobile Division (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. D. L. Pratt: "The Performance of Vehicles Under Trans-Antarctic Conditions".

Institution of Electrical Engineers, London Graduate and Student Section (joint meeting with the Graduate and Student Sections of the Institutions of Civil and Mechanical Engineers, at Savoy Place, London, W.C.2), at 6.30 p.m.—The Rt. Hon. the Viscount Chandos, P.C., D.S.O., M.C.: "Finance and the Engineer".

Society of Chemical Industry, Corrosion Group (at 14 Belgrave Square, London, S.W.1), at 6.30 p.m.—Prof. W. Feitknecht (University of Berne): "Studies of the Influence of Chemical Factors on the Corrosion of Metals" (Spring Lecture).

Institute of Metals (in the Lecture Theatre of the Royal Institution, Albemarle Street, London, W.1), at 7 p.m. Prof. F. Hoyle, F.R.S.: "The Scientific Uses of Space Exploration".

Tuesday, April 14—Wednesday, April 15

Laboratory Animals Centre (at the Royal Veterinary College, Royal College Street, London, N.W.1)—Twelfth L.A.C. Congress.

Wednesday, April 15

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Prof. George C. Varley: "The Biological Control of Agricultural Pests" (Fernhurst Lecture).

Physical Society, Colour Group (at the Victoria and Albert Museum, South Kensington, London, S.W.7), at 3.15 p.m.—Annual General Meeting. Mr. J. W. Perry: "Psychophysical Measurement" (Chairman's Address).

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 5.15 p.m.—Mr. P. A. Stone: "The Economics of Housing and Urban Development".

University College (in the Chemistry Theatre, Gower Street, London, W.C.1), at 6 p.m.—Colonel H. T. Jessop: "Photoelasticity at University College London: Jubilee Commemoration of the Work of E. G. Coker and L. N. G. Filon, 1909–1937"; with an Exhibition of Work in Photoelasticity at University College London, in the Department of Physics (also open April 16 and 17).*

Pharmaceutical Society of Great Britain (at 17 Bloomsbury Square, London, W.C.1), at 7.30 p.m.—Dr. J. B. Stenlake: "Progress in the Chemistry of Natural Products".

Thursday, April 16

Laboratory Animals Centre (at the Royal Veterinary College, Royal College Street, London, N.W.1), at 9.30 a.m.—Symposium on "Quality in Laboratory Animals".

Royal Society (at Burlington House, Piccadilly London, W.1), at 4.30 p.m.—Prof. E. L. Hirst, F.R.S.: "Molecular Structure in the Polysaccharide Group" (Bakerian Lecture).

Institution of Mining and Metallurgy (at the Geological Society of London, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. F. Mendelsohn: "Structure of the Road Antelope Deposit".

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. Kenneth Sporne: "Correlation of Biological Characters"; Prof. H. Grüneberg, F.R.S.: "On Correlation of Characters in the Mouse".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Dr. D. A. Edwards: "Commutative Algebras of Operators".

Institution of Electrical Engineers, Utilization Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Dr. D. O. Bishop and Dr. G. S. Brosan: "An Electromagnetic, Variable-Ratio, Torque Convertor".

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5.30 p.m.—Dr. G. Ainsworth Harrison: "Environmental Determination of Mammalian Morphology".

Society of Chemical Industry, Road and Building Materials Group (at 14 Belgrave Square, London, S.W.1), at 6 p.m.—Annual General Meeting, followed by Mr. R. I. Hughes: "Adhesion in Bitumen Macadam".

Society of Instrument Technology, Control Section (at Manson House, Portland Place, London, W.1), at 6 p.m.—Annual General Meeting, followed by Mr. A. P. Roberts: "Self-Optimising Control System for a Certain Class of Randomly Varying Inputs".

British Computer Society (at the Northampton College of Advanced Technology, St. John Street, London, E.C.1), at 6.15 p.m.—Prof. L. Hogben, F.R.S.: "The Mechanical Translation of Languages".

British Institution of Radio Engineers, Radio Group (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Inaugural Meeting.

Society for Analytical Chemistry, Biological Methods Group (at "The Feathers", Tudor Street, London, E.C.4), at 6.30 p.m.—Discussion on "Problems of Recording and Communicating Technical Information in a Commercial Research Organization", opened by Miss Pamela D. Waterhouse.

Society of Chemical Industry, Fine Chemicals Group (at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Prof. A. Stoll: "The Cardiac Digitalis Glycosides".

British Institute of Radiology, incorporated with the Rontgen Society (at 32 Welbeck Street, London, W.1), at 8 p.m.—Prof. G. Stead: "1895 and All That" (Silvanus Thompson Memorial Lecture).

Thursday, April 16—Thursday, April 30

Engineering, Marine, Welding and Nuclear Energy Exhibition (at Olympia, London).*

Friday, April 17

Institute of Physics (at the Royal Society of Tropical Medicine and Hygiene, 26 Portland Place, London, W.1), at 9.45 a.m.—Symposium on "Current Developments in the Production of High Vacua".

Plastics Institute (joint meeting with the London Section of the Institution of the Rubber Industry, in the William Beveridge Hall of the London University, Malet Street, London, W.C.1), at 10 a.m.—Conference on "Adhesion".

Association of Applied Biologists (in the Metallurgy Lecture Theatre, Royal School of Mines, Imperial College, Prince Consort Road, London, S.W.7), at 2.15 p.m.—Annual General Meeting, followed by Dr. I. Thomas: "Control and Conservation" (Presidential Address).

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 4 p.m.—Symposium on "Biomechanics".

Institute of Navigation (at the Royal Geographical Society, 1 Kensington Gore, London, S.W.7), at 5.15 p.m.—Colonel C. Powell: "The Dectra Trials".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Senior Lecturer in Organic Chemistry; a Lecturer in Chemical Technology; Lecturers (2) in Mathematics; an Assistant (Grade B) in Mathematics; Lecturers (2) in Physics; and an Assistant (Grade B) in Physics—The Registrar, College of Technology, Ashley Down, Bristol 7 (April 16).

Assistant, Grade A (with a degree or equivalent qualifications), in the Department of Pure and Applied Science, Northampton College of Technology, to teach chemistry and physics—The Chief Education Officer, Borough Education Office, "Springfield", Cliftonville, Northampton (April 18).

Lecturer, Grade II (a) (with a good honours degree in physics and teaching and/or industrial experience) in Physics at Dundee Technical College—The Clerk and Treasurer, Institute of Art and Technology, 40 Bell Street, Dundee (April 18).

Lecturer in the Department of Metallurgy, to teach and carry out research in Physical Metallurgy—The Registrar, The University, Liverpool (April 18).

Assay Master—Sir Douglas S. Branson, Law Clerk to the Guardians, Assay Office, 6 Paradise Square, Sheffield 1 (April 20).

Lecturer or Assistant Lecturer (with a good honours degree in chemistry and special qualifications in physical chemistry) in Chemistry—The Registrar, King's College (University of London), Strand, London, W.C.2 (April 20).

Assistant Lecturers (2) in Physics—The Registrar, Queen Mary College (University of London), Mile End Road, London, E.1 (April 22).

Lecturer (with a good honours degree and some experience in research and in industry) in Chemical Engineering—The Registrar, King's College (University of London), Strand, London, W.C.2 (April 22).

Assistant Lecturer in Pure or Applied Mathematics—The Secretary, Queen Elizabeth College (University of London), Campden Hill Road, London, W.8 (April 25).

Chair of Sociology—The Registrar, The University, Leicester (April 25).

Lecturer or Assistant Lecturer in Physics—The Registrar, Manchester College of Science and Technology, Manchester 1 (April 25).

Senior Lecturer in Political and Social Geography—The Registrar, The University, Leicester (April 25).

Assistant Lecturer (with a degree in botany with some zoology) in Biology—The Registrar, University College of North Staffordshire, Keele, Staffs (April 30).

Assistant Lecturers in Pure Mathematics, Electronic Engineering, Chemistry (Inorganic and Physical), Agriculture (Animal Genetics), Marine Biology and Psychology—The Secretary and Registrar, University College of North Wales, Bangor (April 30).

Lecturer (honours graduate in science, with qualifications in two of the following: botany, chemistry or geography) in Education—The Secretary and Registrar, University College of North Wales, Bangor (April 30).

Senior Lecturer in the Department of Physiology, University of the Witwatersrand, Johannesburg, South Africa—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (South Africa, April 30).

Lecturer or Assistant Lecturer in Applied Mathematics—The Registrar, The University, Hull (May 1).

Lecturer (graduate, preferably with honours or higher degree in chemistry) in Chemistry in the Department of Science and Metallurgy—The Principal, North Lindsey Technical College, Kingsway, Scunthorpe, Lincs (May 4).

Lecturer in Nuclear Engineering—The Registrar, Queen Mary College, Mile End Road, London, E.1 (May 6).

Lecturer or Assistant Lecturer in Inorganic and Structural Chemistry—The Registrar, The University, Leeds 2 (May 6).

Chair of Applied Mathematics—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 8).

Senior Lecturer in Medicine at the University of Sydney, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 9).

Lecturer (with British university qualifications, or equivalent, and preferably experience in teaching geography in a university department of geography and geology) in Geography at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 15).

Senior Lecturer (with an appropriate higher qualification and experience in teaching and in research methods) in Medicine at the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 15).

Chair of Physiology in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 30).

Computing Assistant (female, with at least A-level mathematics or equivalent, with hand computing experience), for work in connexion with rocket and satellite studies of the upper atmosphere—The Secretary, University College, Gower Street, London, W.C.1.

Experimental Physicists (with at least a good second-class honours degree, and preferably postgraduate experience in some aspect of nuclear physics), for (*a*) to collaborate with physicists designing a 7 GeV. Proton Synchrotron, to take responsibility for aspects of selection, analysis and transport of high energy beams and eventually to participate in high energy nuclear research; and (*b*) to work with nuclear physicists using a 50-MeV. Proton Linear Accelerator shortly to be commissioned and to collaborate with university physicists using this machine—The Secretary, National Institute for Research in Nuclear Science, Rutherford High Energy Laboratory, Harwell, Didcot, Berkshire, quoting N.1/1/1388/34.

Fisheries Research Officer (with a good honours degree in natural science (zoology) and training or experience in fish ecology) in Nyasaland, for research into the biology and ecology of Lake Nyasa fish—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.152/4/01.

Science Master to teach Physics to A and Chemistry to O level—The Headmaster, Cheltenham College.

Scientific Assistant (Abstractor) (with a degree in agriculture or natural science, and a knowledge of languages)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, Berkshire.

Senior Lecturers and Lecturers in Mathematics and Statistics—The Registrar, Bradford Institute of Technology, Bradford 7.

Senior Plant Pathologist (with a good honours degree in botany, considerable experience in plant pathology, and administrative ability) in Northern Nigeria, for general plant pathology investigations—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/408/039.

Senior Technician (with experience in experimental physiology) in the Physiology Department—The Secretary, Bedford College (University of London), Regent's Park, London, N.W.1.

Zoologist (with at least an honours degree in zoology, biology or entomology of a recognized university, plus at least two years approved postgraduate experience) at the Institute of Medical Research, Kuala Lumpur, Federation of Malaya, for duties which involve research on the ecology of arthropod vectors and on animals as disease reservoirs, with special reference to arthropod-borne virus diseases—The Recruitment and Personnel Division, Government of the Federation of Malaya, Malaya House, 57 Trafalgar Square, London, W.C.2.

SP. 500 SPECTROPHOTOMETER

186 mµ

The Unicam SP.500 Ultraviolet and Visible Spectrophotometer is now fitted with a high grade silica prism which extends the useful working range of the instrument beyond 200 mµ to the region of atmospheric absorption at 186 mµ.

Better prism transmission gives the important advantage of reduced slit widths with a consequent reduction in stray light and increase in resolution, a facility which is especially valuable in the 190-240 mµ region.

A redesigned slit mechanism, in which static friction is virtually eliminated, allows the lowest slit widths to be accurately set and reproduced. Combined with the better transmission of the new prism, this feature greatly increases the scope of the instrument for high resolution determinations at the lower end of the spectral range.

THE NEED FOR A BALANCED EDUCATION

In the fourth of his Reith Lectures on November 30, Prof. A. C. B. Lovell remarked: "The technical devices which form the basis of the present economic and cultural strength of the Great Powers can be traced back within a few generations to fundamental scientific investigations which were carried out in the abstract, supported without thought of direct practical benefit". At least partial realization of this truth is one of the main factors which have been responsible for the steady expansion of the Parliamentary vote in Britain for the universities and for the Government's plans for the expansion of technological and technical education. Nevertheless, the national expenditure on education lags far behind the expenditure on education in the United States and in the U.S.S.R., as well as in other countries. Russian expenditure on education in 1959 is estimated at about £8,420 million, compared with £5,340 million in 1958, with £2,480 million for science and a military budget in 1959 of £8,740 million.

Dr. B. V. Bowden has recently given some comparative figures for the United Kingdom and for the United States, where some 5,000 million dollars are estimated as required in the next ten years to provide facilities for the expected increased undergraduate population; some 300 million dollars of this total is required for science laboratories. The University Grants Committee in Britain deals with twenty-one universities, one university college and two colleges of technology; in addition, there are 153 teachers' training colleges, eight colleges of advanced technology, some thirty-six advanced colleges of art and commerce, half a dozen colleges giving specialized courses, and about a hundred technical colleges giving full-time tuition to senior students. In the United States there are some 1,800 institutions of advanced study, ranging from universities with more than 40,000 undergraduates to colleges with only fifty. While only 9 per cent of the school-children in Britain enter the sixth form of grammar and secondary schools, and between 4 and 5 per cent go to universities or colleges, in the United States nearly all children remain at high school until the age of seventeen or eighteen, and last year 34 per cent of the 18–21 age group enrolled in college.

The probability that an American child will go to college is thus about four times as great as the probability that an English child will enter a sixth form, and the 95,000 students in British universities and 15,000 in training colleges compares with a present 2·7 million students in the United States and an increase to nearly 7 million by 1970, when the university population in Britain is expected to reach 142,000. When all allowance is made for the great variation in standards in American universities, for the high proportion—almost 50 per cent—of students who are unable to complete the course, and for the probability that much of the first year's work in an American university is done in the schools in Britain, the disparity is disturbing. Nor is it less so in regard to postgraduate students; the 10,000 students reading for postgraduate degrees or doctorates based on research in Britain compare with about 250,000 in the United States; and although the percentage of students who are postgraduates is about the same in both countries, there were 2,600 postgraduate students at the Massachusetts Institute of Technology alone, compared with 1,577 postgraduate students of technology in the whole of the United Kingdom.

It would be absurd for Britain to attempt to expand university and technological education on such a scale. The comparison rather emphasizes the importance of seeing that institutions in Britain at all levels are adapted to the tasks they are called upon to undertake, that the utmost care is taken to discover talent, to eliminate waste at the various levels and to ensure that the most effective use is made of trained man-power when it enters industry or other employment. Prof. Lovell in the lecture already mentioned said that unless the West overcomes its present parsimonious attitude to science and technology, the relative quality of our civilization will decline and our influence will pass to other people; and, although he was thinking more particularly of research, that comment applies no less forcibly to education. There, least of all, have we provided the facilities necessary for our existing scientific man-power.

Leaving for the moment the magnitude of expenditure in Britain on education, there is the question of priorities. Unless these are properly determined, and periodically adjusted to changing circumstances and needs, we are unlikely to obtain full value for our expenditure whatever its magnitude. If priorities are rightly chosen and care is taken to see that trained man-power is wisely and efficiently used, Britain's needs will be met with a much smaller total expenditure and one well within her comparatively limited resources, provided the appropriate measures are consistently supported and are not made the playthings of party politics.

That is largely a matter of educating public opinion, and at this point education is linked with the work of such bodies as the British Association. Addressing the annual meeting of the Indian Science Congress in New Delhi on January 22 on the work of the British Association, the Duke of Edinburgh expressed the opinion that one of the three objectives of the Association, namely, to provide for non-specialists an annual stocktaking in intelligible language which would review the progress of science and help to make clear its significance and possible consequences, is more important than ever. Every human invention or discovery can be used, he said, for good or for evil, and in the end it is the people as a whole who will decide which it is to be. It is therefore essential that the possible consequences of scientific research should be put before the forum of ordinary people. Only in this way can the combined opinion of reasonable, upright and humane men and women throughout the world exert the necessary pressure to ensure that science is used to set free and not to enslave mankind.

That is notably true in respect of education as a whole, and the Duke of Edinburgh's remark earlier in his address, that the Association had become a very useful platform for scientists to express their opinion on Government scientific policy, also applies to educational matters. Besides this important function, the British Association has indeed formed, as part of a wider programme to develop the educational programme for young people, a study group to examine the educational system for scientists.

The determination of priorities, however, is outstandingly a matter of co-operation. In his fifth Fawley Lecture on November 6, 1958, Sir Harry Pilkington, speaking of "Facing the Future in Industry", stressed the need for industry to increase the time given to internal training as well as to external education, to learning and earning at the same time, and referred particularly to the growing demand for informed judgment and consequently higher standards of management and leadership. If full use is to be made of the opportunities which science now presents, time, effort and money must be directed to the right objectives, and he believes that disciplining research effort is essential; in many industries the glamour attached to research impedes co-ordination between research, technical development and production, and may lead to loss of leadership.

Whether industry is able to work out, as Sir Harry suggests, a constructive code and philosophy of co-operation and then take on a much more positive attitude to combination and co-operation on technical and commercial subjects, and whether it can also hold its own against the growing industrial power of totalitarian countries, depends largely on the talent it is able to attract. That of itself suggests that a first priority in education should be, if not the actual search for talent, at least positive measures to ensure that the chances of talent failing to be encouraged and developed from any cause are kept to a minimum. In a recent article in *European Productivity* (No. 29; June 1958) on "Western Europe's Buried Talents", Dr. R. Schairer suggested the formation of a study group of men and women experienced in the promotion of talent, to examine the factors such as talent development, poor teaching methods, shortage of school accommodation and early entry into industry, which are responsible for loss of talent, and to study methods for fostering its development. Dr. Schairer believes that 10 per cent of all funds for educational and scientific development should be earmarked for the search for talent, including the earmarking of scholarship funds for the discovery and promotion of creative talent, especially in the age group 20–50. In this connexion, it may be noted that in a foreword to the recent pamphlet on "Teaching Mathematics in Secondary Schools", Mr. Geoffrey Lloyd said we had clearly reached a stage in which our methods and curriculum need to be considered afresh.

If the discovery of talent is a first priority, and the educational system of Britain should be constructed so as to ensure that, so far as possible, no school-leaver capable of benefiting by a university education should be debarred by lack of means from entering a university, it does not follow that room must be found in the universities for all who seek admission and have obtained the basic qualifications, whatever they may be. Creative talent is not necessarily best developed in a university, and if all real ability is channelled through the universities, the effects on various aspects of national life may well be adverse; quite apart from whether the nation can afford the necessary expansion in the resources devoted to university education. The expansion of university and technological education has clearly to be planned in some relation to the supply of appropriate talent; but it should also be in balance with the capacity of the educational system both to supply the supporting technicians and craftsmen needed for efficient use to be made of the most highly trained and creative man-power, and also to ensure that the general body of citizens has a lively appreciation of the issues involved. It is as vitally important to see that the main body of school leavers are adequately educated and able to face the demands of life in an age of rapid technological change, as it is to ensure that the best use is made of the brain-power available.

The recent White Paper on Secondary Education in Britain struck the right note in its emphasis on parity of opportunity, and the development of the educational system so that it can better produce citizens who are fitted by character, knowledge and skill to play their full part in an increasingly educated and responsible democratic society.

QUEEN AND SERVANT OF THE SCIENCES

Teaching Mathematics in Secondary Schools

(Ministry of Education Pamphlet No. 36.) Pp. viii+154. (London: H.M. Stationery Office, 1958.) 6*s*. net.

MUCH has recently been said and written about the claim that mathematics is a language, and in the foreword to this excellent volume (too valuable and too comprehensive to be termed a pamphlet), the Minister of Education himself asserts that the subject must be "taught as a language". Those who have made mathematics their special study will need no convincing that it *has* a grammar, a literature and a poetry. In the years before the Jeffery syllabus, which here receives critical examination and strong support, far too many boys and girls left school having spent a part of every school day working at 'maths' without being allowed (as was Moses) to gain even a glimpse of the Promised Land. In fact, they probably never knew that there was anything worth working for, anything but 'sums' and (worse still) 'problems'; they had all the drudgery of the driest of the grammar and none of the fun of the literature, much less the poetry. But for one limiting factor (to be mentioned below) this should no longer be the case for any of the teeming multitudes in the secondary schools of Great Britain, and the various chapters in this book set out clearly and enthusiastically why (and to some extent how) this can be accomplished. No authorship is, of course, ascribed to this official publication, but one thing is certain: 'they' have all taught the subject successfully, for only after experiencing the thrill of success with a class could these chapters have been written.

Every library in Britain should have copies of the book on its shelves, if only because it contains a valuable account of the development of mathematical teaching in England (and Wales ?) since the middle of the nineteenth century. A footnote (p. 67) reveals the authorship of the first official publication (Circular 711; 1909), which guided the schools in using the new-found freedom from the "bad parts of the Euclidean tradition". By the saddest coincidence, W. C. Fletcher (1865–1959) died two days before Pamphlet 36, which thus pays tribute to his great work for school mathematics, was published. All teachers of mathematics—not only those who dare to call themselves mathematicians—should read, mark, learn and inwardly digest this new book. In it they will find the encouragement to make themselves better able to teach, and the advice that the reports of the Mathematical Association provide the best means of doing this.

The rest of the volume gives an excellent outline of the present position (Chapter 2) in English secondary schools, goes on to show (Chapter 3) how essential it is to understand what has been done in the primary schools, and Chapter 4 discusses critically much of what is done (and should not be) in many secondary schools, as well as giving much sound advice on what should be done in the next four or five years. These years, which for the majority of boys and girls have no General Certificate of Education or any other examination at the end of them, will contain the only full-time instruction in mathematics these young people will receive. How essential it is, therefore, that the content and the approach (Chapter 6) should be the right one.

Chapter 5 is concerned with the sixth form, and emphasizes the risks we run if pure geometry receives less and less time and attention. Technique in the classroom, including comments on homework and marking (Chapter 8), and the relationship of mathematics to other studies (Chapter 7) are carefully treated, and the importance of an adequate background of the history of mathematics (Chapter 9), so that the teacher may weave a golden thread through all his lessons, is emphasized with appropriate examples.

The limiting factor in all this is, of course, the dire shortage of capable teachers, and without them the high ideals inspired by the report cannot be fully achieved. Yet even here there is cause for hope. "The fear of mathematics is more widespread than it should be", and "girls capable of going far in the subjects are more numerous than is commonly supposed" indicate that it should be possible to inspire a greater interest and facility in many more young people if "a real attempt is made to fit the mathematics to the pupil". Even with the present teaching staff, many of whom are gallantly attempting to teach up to the limit of their own accomplishment, much more can be achieved through the right approach and the best methods. By this means more boys, and especially more girls, may be encouraged to specialize in this subject, and so enable Britain "to remain in the forefront of scientific advance".

W. J. Langford

ATOMIC COMFORTS

On Nuclear Energy

Its Potential for Peacetime Uses. By Donald J. Hughes. Pp. xi + 263. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1957.) 30s. net.

This book represents one of the first attempts to combine an account suitable for the layman of the fundamental physical facts of nuclear energy with a discussion of its national and international implications, in particular of the possibility of development by peaceful international co-operation. In a foreword, Mr. Lewis L. Strauss describes one part of the book as being "one of the most complete and responsible surveys of the subject to appear in print". One fears the worst after this: fortunately, one's worst fears are not quite realized.

But in the chapter entitled "The International Atom"—even though the sub-section in question is headed "International Atomic Energy before Geneva" and the Geneva Conference on the Peaceful Uses of Atomic Energy was held in 1955—nothing is said of the period between 1945 and 1953. The year 1953, the first year of the Republican administration in the United States under President Eisenhower, is treated as the start of the period of international negotiation. Would it have been irresponsible to mention the diplomatic struggle of the first seven or eight years—the first half, indeed, of the atomic age ?

In a later chapter having a sub-section headed "Safety in Bomb Tests", the author takes two-thirds of a page to discuss whether to discuss this matter, then less than three pages to dispose of it. Although the dangers of radioactive strontium are mentioned (in two paragraphs), leukæmia is not, and no quantitative statement is made—even of the range covered by the (irresponsible ?) estimates of danger.

Perhaps the real difficulty is that all but about a third of this quite short book is devoted to the necessary layman's introduction to nuclear energy, with chapters headed "Fundamentals of Fission and Fusion", "The Chain Reaction", "Atomic Power", "Neutrons from Reactors", "Radioisotopes", and "Fusion". This part is competent, though undistinguished, but it leaves too little space for the rest, the chapters which the now educated layman must study before he can know what are the problems before him.

Dr. Hughes's repetitive and muddy style of American writing reduces further the amount of information which he can convey. To quote a few sentences out of context: "The destructive phases of fission and fusion energy are practically completely involved with their use as military weapons". "It is a matter of statesmanship to assure that man's life shall be enriched and not destroyed by the developments, rather than to halt a branch of research by edict." "It is interesting, however, that in both personal and information security the concept of negative and positive aspects just discussed plays an important role." Such a style makes clear thought difficult, and it is to be doubted whether the author could have steered us through the really controversial questions in his field. He mentions controversies which have arisen, but a little regretfully. On one question, that of security, he takes a forthright stand, pointing out the danger, even from the strictly national point of view, of too much "negative security".

The book does give a reasonable account of the status of the main national atomic energy projects, and is perhaps at present the best compact source of this information. On the whole, however, I find it too responsible, too comfortable, and too non-controversial. A determined and well-meaning layman who worked through it would scarcely know what all the fuss had been about. G. O. JONES

QUADRUPOLE RESONANCE

Nuclear Quadrupole Resonance Spectroscopy

By T. P. Das and E. L. Hahn. (Solid State Physics: Advances in Research and Applications, Supplement 1.) Pp. ix+223. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1958.) 7 dollars.

THE subject-matter of "Nuclear Quadrupole Resonance Spectroscopy" is the resonance phenomenon associated with transitions between states the energies of which depend on the interactions of the nuclear electric quadrupole moment with the field gradient provided by the environment of the nucleus. A small magnetic field may be applied in certain cases and its influence is then treated as a perturbation. The converse case of nuclear magnetic resonance in which the quadrupole effects may occur as a perturbation was dealt with in an earlier volume of this series.

The basic physics of the subject is now well understood and quadrupole resonance thus takes its place as an analytical technique of use both to the solid state physicist and the chemist. This book consists of about 80 pages of theoretical discussion, 10 pages on experimental technique and a little more than 100 pages on applications. The reader is referred elsewhere for a discussion of the fundamental theory, and the account of the applications is not claimed to be exhaustive; but in other respects the book is fairly complete.

One of the practical advantages of quadrupole resonance spectroscopy is that it may be carried out without the use of large and expensive magnets associated with nuclear magnetic resonance experiments. On the other hand, the apparatus employed must be made to tune through a very wide band of frequencies and it is therefore usual to use the damping of what is essentially a super-regenerative receiver as a means of detecting resonance. In such a system it is only necessary to vary one tuned circuit. The descriptions of several satisfactory circuit arrangements have been published and references are given.

The applications discussed in most detail are the determinations of the orientations of molecules in the unit cell and the study of the nature of bonding in various solids.

The work as a whole provides a valuable general introduction to the subject and is likely to be of particular interest to chemists. It is to be regretted that the proof reading was not carried out with more care. R. H. TREDGOLD

RATIONAL DISCUSSION

The Logic of Scientific Discovery

By Prof. Karl R. Popper. Pp. 480. (London: Hutchinson and Co. (Publishers), Ltd., 1959.) 50s. net.

IT is customary to believe that scientific method has been explained by Bacon and Mill once and for all. Yet science has changed greatly since these two men—who were not scientists—wrote; and so its methods must have changed as well. Einstein, in his Spencer Lecture given at Oxford in 1933, was the first to point out this change. We do not gain knowledge by reading 'the book of Nature' or by following 'a principle of induction'. We start, instead, by inventing a hypothesis and then proceed to test it by its consequences.

This hypothetical-deductive method was developed in detail by Prof. Karl Popper in the German version of the present book, "Logik der Forschung", published in Vienna in 1934. Pre-war conditions prevented the book from being easily accessible in the English-speaking world. Nevertheless, its ideas infiltrated, so that to-day there exists scarcely a philosopher or scientist who does not reject 'inductivism' and accept the hypothetical-deductive method.

The crucial experiment, according to Popper, is the means by which we decide whether or not to accept a hypothesis or theory. In such an experiment, like Michelson's, we try to falsify a hypothesis. If the outcome is positive, that is, if the singular statements derived from it have not been falsified, the hypothesis has withstood the test and is accepted. A hypothesis is never conclusively verified, for it is usually a universal statement; and no finite series of tests could ever establish its truth or falsity. Such a statement, however, is logically equivalent to a negative existential one, and this can be overthrown by a single experiment. Thus a hypothesis 'proves its mettle' or a theory is 'corroborated'. 'Confirmation', which is the common term describing this situation, is rejected by the author, for it suggests that we can firmly establish a hypothesis; and this is never so in science.

Another reason for rejecting induction is that it does not provide a criterion which would allow us to separate science from empty speculation or physics from metaphysics. This is, indeed, a basic problem, well known from the history of science: many attempts have been made to solve it. Physicists usually speak in this connexion of 'meaning'. Factual statements are meaningful if they can be tested by experiment, at least in principle. For example, statements referring to the simultaneous and exact values of position and momentum of a particle are meaningless in quantum mechanics, since they are ruled out by the uncertainty relations. Prof. Popper altogether rejects a criterion of meaning and replaces it by one of demarcation that is agreed upon by convention and "ultimately a matter of decision, going beyond rational argument". Indeed, what we accept as factual or real changes with the progress of science and is not decided by words; but a criterion of meaning could, in my view, do this job as well.

The more falsifiable a hypothesis is, the more it forbids, the more does it say about the world. This is the well-known inverse relation between logical range and factual content of a statement. The hypothesis which is falsifiable in a higher degree can also be corroborated better; and this depends less on the number of favourable instances than on the severity of the tests the hypothesis had undergone. The degree of falsifiability is complementary to logical probability which, however, must not be confused with numerical probability as we know it from statistics. According to Prof. Popper, statistics cannot help us in corroborating a hypothesis. His views on probability are highly controversial and, I fear, will not be readily shared by practising scientists.

The original text has been enlarged by footnotes and appendixes which make up more than one-third of the book. These additions do not help the book, not only because they are difficult to read, but because they are unduly polemical. A larger criticism is that physics is the only science talked about by the author. However, the rational discussion of its concepts—which Prof. Popper regards as "the one method of philosophy"—results in laying the ghost of induction, and this is the outstanding merit of the book.

E. H. Hutten

NATURAL HISTORY OF BRITISH SPIDERS

The World of Spiders

By Dr. W. S. Bristowe. (The New Naturalist: a Survey of British Natural History.) Pp. xiii+304+36 plates. (London: William Collins, Sons and Co., Ltd., 1958.) 30*s*. net.

ALTHOUGH an extremely widespread invertebrate group, spiders have for long been avoided by most British naturalists, amateur and professional. The reasons are probably straightforward: spiders have no æsthetic appeal to the amateur, as have, for example, Lepidoptera, beetles and dragonflies, while the professional has always regarded their biological importance as very low. None of the British species can be regarded as pests in any way, and although they must rank as one of the most important invertebrate predators, their choice of prey is to a great extent non-selective and no means have been found of using their activities to regulate harmful insects or in other ways. Until recently, their interest to the biologist has largely been academic, and the great names in the history of British araneology have been almost all taxonomists. To Dr. Bristowe must go the credit of rediscovering spiders for naturalists in Great Britain, not as lifeless pickled specimens, but as living creatures with activities and behaviour patterns of incredible diversity and quite as fascinating as any other invertebrate group. This book has an unrivalled wealth of personal observations on a great many different species of spiders, both captive and in the field, all of which have been made in his spare time during a busy professional life.

The first two chapters deal with two subjects which are characteristic of Dr. Bristowe's wide interest: spiders in literature and superstition, and what might be called a natural history of British araneologists. Together they form an excellent introduction to the main part of the book and will appeal to all naturalists whether they have a knowledge of spiders or not. Chapters 3 and 4 deal with structure, classification, and the fossil record. Chapter 5 touches all too briefly on the subject of population densities of spiders, and the influence of these numbers on other invertebrates. The next fifteen chapters describe and discuss the biology and behaviour of selected species of all the spider families represented in Great Britain.

While the character of the individual spiders is vividly portrayed by Dr. Bristowe, a less clear picture emerges of the ecology of spider communities. The book is, of course, concerned with the British fauna, but as studies on spider ecology are all very recent and include so much original work and new discoveries, some account of them would have helped to complete the picture. No reference is made, for example, to the excellent studies by Nørgaard in Denmark on the ecology of the *Pirata* species, of *Theridion saxatile* and *Lithyphantes albomaculatus*, all represented in Britain, nor to the population studies in Germany by Bochmann and Knülle on salt-marsh spiders, and by Tretzel and others on terrestrial habitats. A wide new field has developed on this subject during the past twelve years which shows excellent promise of narrowing the gap between our knowledge of spider ecology and that of better-known invertebrate groups.

There is a final chapter on collecting spiders, an up-to-date species list as an appendix, and a short bibliography.

One of the most impressive features of the book is the really excellent series of 332 drawings in line and wash by Arthur Smith. These were specially made for the book and immediately places this volume of the "New Naturalist" books in the front rank of the series for accurate and beautiful illustrations. Dr. Bristowe writes as an enthusiast in a fluent and very readable style. It will be no surprise if this book results in many converts to the study of spiders.

Eric Duffey

CARBOHYDRATES COMPLETE

The Carbohydrates

Chemistry, Biochemistry, Physiology. Edited by Ward Pigman. Pp. xvii+902. (New York: Academic Press, Inc.; London: Academic Books, Ltd., 1957.) 20 dollars.

FOR some years the Pigman-Goepp book on the "Chemistry of the Carbohydrates" has been the main reference book for carbohydrate chemistry. The book now under review is a complete revision with a considerable expansion of the earlier Pigman-Goepp. For this compilation the editor, Ward Pigman, has brought in no less than twenty specialists in the field to assist him. They have succeeded in adding two new chapters in addition to re-writing and bringing up to date all the previous chapters in the "Chemistry of the Carbohydrates". The vast increase in the volume of publications on carbohydrates is illustrated by the claim of the editor that references are given to no less than 4,500 individual articles. At first glance the book looks like a 'big brother' of any one of the current volumes of the "Advances in Carbohydrate Chemistry" published by the same press, but on closer inspection it is quite clear that much more detail has gone into the new individual chapters. These serve to make the book an excellent reference book which can be used in conjunction not only with the "Advances" but also with the older edition, which does contain some material eliminated from the present book.

The first three chapters, "Structure and Stereochemistry of the Monosaccharides", by Ward Pigman, "Occurrence, Properties, and Synthesis of the Monosaccharides", by John Sowden, and "Esters", by A. Thompson and M. L. Wolfrom, follow the conventional lines of the first book; they are, however, much more comprehensive and are now well developed, and references are given in an exhaustive fashion. The chapter on "Glycosides, Simple Acetals, and Thioacetals", written by M. L. Wolfrom and A. Thompson, again contains much of the material of the older edition, but gives a better account of the reactions of carbohydrates with aldehydes and ketones: this treatment is excellent. "Polyols, Alditols and Glucitols", written by R. L. Lohmar, jun., represents an extension of previous work and gives a most interesting account of this expanding class of sugar derivative. In addition, the related inositols come in for up-to-date treatment and the whole chapter is important and timely.

Another extension is the discussion of acids and oxidation products by John W. Green, where aldonic acids, aldaric acids, uronic acids, ascorbic acids, and so on are treated together. Most important, the section on oxidative reagents which are of special application in carbohydrate chemistry has been extended.

Ethers, anhydro-sugars and unsaturated derivatives are dealt with in some detail in a clear-cut manner by John C. Snowdon. A very welcome account, since the subject is growing rapidly every day, is that on nitrogenous derivatives written by Ward Pigman with specialist collaborators. The rapid growth of this subject is clearly demonstrated by the fact that no less than seventy pages are devoted to the different aspects of the sugars containing nitrogen. Another almost equally long chapter is that on oligosaccharides, carefully written by W. Z. Hassid and C. E. Ballou. The reader is brought up to date on enzymic synthesis of oligosaccharides in this chapter and modern advances in enzymic studies in this field are well illustrated.

An important and well-written chapter is that on the identification and quantitative determination of carbohydrates by Ray Noggle, though this could well have been placed at the beginning of the book. It is interesting because it includes some work on isotope procedure, including the synthesis and degradation of labelled sugars. The chapter on polysaccharides has been sub-divided into phyto- and microbial polysaccharides and animal polysaccharides. It has been cut down somewhat from the earlier publication and is perhaps the least praiseworthy in the book. This is because there has been a great attempt to put *multum in parvo*, so that a catalogue is now provided which, although it may serve to whet the appetite, appears to be somewhat stilted in the way it is written.

An attempt to introduce yet another classification of the animal polysaccharides with new terms adds but little to an already confused nomenclature. However, the account is well provided with references and will be important from the library point of view.

An excellent chapter on the photosynthesis and metabolism of carbohydrates is produced by Ray Noggle. This is very important and it well illustrates the rapid development in this particular field in the past few years.

Finally, there is a chapter on "The Carbohydrates in Nutrition", by Harry G. Day and Ward Pigman. This is most interesting, it is well written, and adds in more ways than one yet another chapter to the story of our carbohydrate chemistry.

Taken as a whole the book is an excellent one. It will be consulted by chemists, biochemists (academic and industrial), by medicals, and all students of chemistry. An enormous amount of effort has undoubtedly gone into the book and Ward Pigman is to be heartily congratulated on his efforts.

There are very few typographical errors and the style, well known in the "Advances in Carbohydrate Chemistry", is very acceptable. An important fact is that the modern Anglo-American carbohydrate nomenclature has been used throughout.

M. STACEY

ABORIGINAL ART

The Tiwi

Their Art, Myth and Ceremony. By Charles P. Mountford. Pp. 185+64 plates. (London: Phoenix House; Melbourne: Georgian House, 1958.) 65*s*. net.

THE aboriginal art of Arnhemland in Northern Australia is particularly rich in the variety of its forms, technical control and harmony of colour and design. Tools and materials are of the simplest: cave walls, bark, wood and cane; black pigment, red, yellow and white ochres; brushes made from bark; and fixatives derived from the sap of tree orchids or from a mixture of wax and honey. Most men can paint and carve but some are more skilled than others and acquire a reputation within their region. Nevertheless, all work within the same tradition, and no premium is placed on individuality and innovation.

We already have two monographs dealing with art in Arnhemland, one by Mountford (1956), and an earlier one in colour by Elkin and Berndt (1950). The present volume is concerned with the art of Melville Island, 14 miles to the west, where a distinctive style has been developed in the treatment of figured bark paintings, carved and painted burial poles, decorated bark baskets and ceremonial spears. As elsewhere in Australia, most of these objects are produced for a ceremony, and their value is of an especially sacred character in so far as they form an integral part of the rite, and portray in geometrical and naturalistic figures the supernatural beings and events occurring in myths. Mountford makes the point that Tiwi art is more highly formalized than that of the east and cannot be interpreted without the aid of the artist. The interpretations of the paintings reproduced in black-and-white in this book are recorded by Mountford; what he does not tell us is how far similar interpretations were or would have been offered by other adult men in the community. Nevertheless, it is valuable to have at least the artist's point of view; and this, along with the superb photographs, make the book a useful contribution to studies of aboriginal art.

From the anthropologist's point of view the book is disappointing in that both title and publisher's note are misleading. Mountford does not give us an analysis of all Tiwi myth and ceremonial, but confines himself to a description of the ceremonies of mourning and initiation witnessed by him and the myths associated with them. He omits to give an outline of the social organization, though a knowledge of this is essential for a full understanding of myth and ritual. He himself, as leader of the expedition, had little time for research, but he might have made use of material already published by field-workers and listed by him in his bibliography.

PHYLLIS KABERRY

La Disputa Leibniz–Newton sull'Analisi

(Enciclopedia di Autori Classici, 2.) Pp. 239. (Torino: Editore Paolo Boringhieri, 1958.) 1,200 lire.

THIS valuable little book contains the principal documents in the Newton–Leibniz controversy over the invention of the infinitesimal calculus, translated into Italian and briefly annotated by Dr. G. Cantelli. Of these, the most important is the long review (generally held to be by Newton himself) from the *Philosophical Transactions* of 1715, which sums up carefully, but decisively, in the author's favour. To present-day readers, however, the most interesting things in it are the incidentals. Thus Newton claims that his method of fluxions is more rigorous than Leibniz's theory of differentials, since "we can form no idea of infinitely small quantities". Again, Newton admits that the majority of the results in the "Principia" were obtained by his new analysis and only afterwards clothed in geometrical form. Finally, he goes beyond the limits of the controversy to attack his rival's natural philosophy. Between Newton and Leibniz lies "an enormous difference": the first proceeds only so far as experimental evidence leads and then stops, while the second is a slave to hypotheses which he blindly believes as eternal truths.

On the other side of the dispute Leibniz, from modest beginnings and courteous exchanges, gradually raises the stakes as his honesty and good faith are increasingly questioned by Newton's friends. Expressions of admiration for Newton's genius give place to complaints and accusations; the claim to independent discovery becomes an assertion of priority. Then his supporter, John Bernoulli, plays his trump card: if Newton had in fact discovered the calculus earlier, why did he not use it in the "Principia", which offered so many opportunities for its application? Instead, there is not a trace of analysis in the whole work. . . .

What are the rights and wrongs of the quarrel? The editor confesses that he is at a loss to say. It would be safer to maintain, with Wallis, a neutral position and ascribe the invention of the calculus to neither party but to the pioneers, above all to Cavalieri and Newton's own teacher Barrow.

L. Roth

Systematic and Experimental Studies on Protozoal Blood Parasites of Egyptian Birds

By Dr. A. H. Helmy Mohammed. Vol. 1: Pp. xi+166 (plates 1–6). Vol. 2: Pp. ii+167–298 (plates 7–13). (Cairo: Cairo University Press, 1958.) n.p.

THE book is the outcome of a survey, for protozoal parasites, of birds collected, near Cairo, over two complementary halves of two years, during which time some 885 birds were examined. It is, then, a report on the personal research of the author and serves, not as a general text-book but as a useful reference book for the limited few working in similar fields. Of necessity it varies in the accuracy of the incidence figures according to the methods of examination and to the numbers of a host species examined, and, in common with other works of this kind, does not claim to be complete.

The first section is devoted to speculations on the meaning of the figures for incidence listed early in the report; some are based on evidence too scanty to be of any practical importance; others, for example the use of evidence on distribution of the parasites to hint at the identities of their vectors, may be used profitably by future workers. This is followed by three sections dealing in turn with the species of Piroplasms, *Plasmodium* and *Haemoproteus*, found in the survey, together with reviews of the systematic problems surrounding these parasites. Dr. Mohammed includes sufficient information to clarify the problems in hand without attempting general reviews. The last section is an account of the development of *Haemoproteus columbae* in the pigeon fly, *Pseudolynchia canariensis*, a confirmation and extension of the work of H. Adie in 1915.

Elizabeth U. Canning

A Guide to Field Biology

By John Sankey. Pp. xvi+166. (London and New York: Longmans, Green and Co., Ltd., 1958.) 12*s.* 6*d.* net.

IT is particularly appropriate that the author of this admirable little book should be a warden at one of the centres of the Field Studies Council, which has played a notable and pioneer part in encouraging field biology in secondary schools in Britain. As might be expected of one with ten years experience in this type of teaching, Mr. Sankey's account is lively and practical in outlook. Ecology is a subject which is not easy to teach or to write about. The simple and straightforward approach adopted in this book should go far towards dispelling any doubts, still often voiced in educational circles, that field-work is too complex to be undertaken profitably without elaborate apparatus and a disproportionate expenditure of time. Guidance is given on how to study particular kinds of plant and animal habitats and there are useful sections dealing with such aspects as the planning of projects, also methods of collecting and identification.

W. H. Dowdeswell

Venture to the Arctic

Edited by R. A. Hamilton. (Pelican Book No. A432.) Pp. 283+32 plates. (Harmondsworth, Mddx.: Penguin Books, Ltd., 1958.) 5*s.*

THIS book performs a new and very welcome function in the sphere of expedition literature. It tells, in terms of popular science, the story of the British North Greenland Expedition of 1952–54. The main narrative of any expedition, normally written by the leader, cannot find room for more than a few pages on this, and anyway, is almost always written before the results are known; and the results themselves are both too technical and scattered over a wide range of journals. This book is directed to the 'man in the street', who is entitled to hear about what he has helped to pay for. He will find it of fascinating interest, and his idea of what a modern scientific expedition accomplishes will probably be considerably extended. But although it is designed for the non-specialist, the contributors have rightly understood that popularization implies simplification of language rather than of ideas, so that the specialist will also gain from reading it. R. A. Hamilton, as chief scientist, fills in the background of planning and organization, and contributes his own meteorological results, besides editing the whole. F. R. Brooke describes the survey, C. B. B. Bull the seismic sounding and gravity work, J. P. Masterton and H. E. Lewis the medical and physiological aspects, H. Lister the glaciology, J. D. Peacock the geology and P. J. Wyllie the geomorphology. It is much to be hoped that other expeditions will follow this lead. They could have no better example before them.

T. E. Armstrong

THE ZOOLOGICAL SOCIETY OF LONDON

By Sir SOLLY ZUCKERMAN, C.B., F.R.S.
Secretary, Zoological Society of London

OVER the past eighteen months the affairs of the Zoological Society of London have attracted considerable attention in the national Press, first because of a proposal to alter the Society's by-laws, and more recently through the publication of plans for the reconstruction of the Regent's Park Gardens. Alterations in the Society's by-laws can be proposed only by the Council; but the constitution demands that they have to be endorsed by the body of Fellows. The 1958 proposals, one of the main objects of which was the strengthening of the scientific and educational activities which are the sole purpose for which the Society was incorporated by Royal Charter in 1829, were accepted by well over half the 3,000 Fellows who took the trouble to vote. One of the dissenting minority decided to challenge the Council on the construction of the by-law defining a majority, his argument being that in order to validate any proposal about by-laws it was necessary to obtain an absolute majority of the 7,000 or so Fellows in the Society, whether or not they voted. This view was upheld in the Chancery Division on December 5, 1958, but reversed in the Court of Appeal on March 20, 1959.

To see this affair in perspective, it is useful to consider the past history of the Society; its future plans; and the purpose of the 1958 changes in the by-laws, which have now become effective.

History of the Society

The Society was founded by Sir Stamford Raffles and Sir Humphry Davy, then president of the Royal Society, "for the general advancement of zoological science". As an immediate object it was hoped to collect in London "such living species of the animal kingdom as may be introduced and domesticated with advantage in this country". It was also suggested that the Society should found both a zoological museum and "a Library of all Books connected with the subject". The first problem was to find the money necessary to realize these objects, as well as the authority to establish a menagerie on Crown land in Regent's Park. Almost inevitably the Fellowship became a combination of professional zoologists, and of subscribers who ranged from amateurs with a deep specialist knowledge of a particular part of zoology, to persons to whom membership was little more than a means either of granting patronage or, in some cases, of gaining prestige or privilege. There was no alternative to this development if the resources were to be found.

After considerable negotiation with the Government, a lease of five acres of Regent's Park was granted in 1826, which was soon increased to about thirty acres. Within ten years there were 3,000 Fellows, and for the first twenty years or so entrance was restricted to them and their friends, since they, in effect, were the patrons whose contributions had made the venture possible. Their number then started to decline, and in 1847 it was decided to admit the public by payment at the gates. The reason for this departure was essentially financial, even though the Council of the day was authorized to express the Crown's approval of the step as a measure which helped to diffuse "intellectual recreation among the great mass of the people". The decision brought an immediate improvement in the Society's fortunes. Within three years total revenue had all but doubled, and Fellows' contributions fell to about 40 per cent of a budget of about £15,000. In 1900 incomings were about £29,000, to which Fellows contributed about 38 per cent. By 1938 the proportion had fallen to 16 per cent, and to-day it is only about 5 per cent of the half-million pounds a year now needed to administer the collections of animals in Regent's Park and in Whipsnade Park, nr. Dunstable, Beds, and the Society's many other activities.

The spark which touched-off the recent dispute in the Society's affairs was a decision by the Council to open the Regent's Park Gardens to the public on Sunday mornings, which *ipso facto* meant the withdrawal of a privilege of restricted entry which was highly valued by some Fellows. One of the main reasons for this decision was the Society's urgent need for funds to meet rising costs and to start a major rebuilding programme. Sunday afternoons, which had been 'public' since 1940, already provided through gate receipts relatively more to the Society's revenues than the takings of any full day of the week. Additional receipts on Sunday mornings over this past year have practically equalled the total net revenue received from Fellows. The question of rates was the second main reason for the decision to open the Gardens. The Council had been advised that only a substantial increase in the amount of voluntary subscriptions, and a decline in the proportion of the subscriptions from which the Fellows derived a personal benefit, would make it possible for the Society to qualify for exemption from liability to rates as a scientific society under the Scientific Societies Act of 1843. The withdrawal of the privilege of exclusive entry on Sunday mornings has already materially altered the situation.

The uproar this occasioned did not come from the hard core of professional zoologists who are members of the Society. For many years there appears to have been an attitude within the administration of the Society that all subscriptions to its coffers were to be welcomed, whatever their source. As a result, the Fellowship of the Society has at times risen to as many as 8,000, and it is not surprising, therefore, that some of those who became Fellows were unaware of the fact that the existence of the Zoological Society as an institution under a Royal Charter depended solely on the fulfilment of the object for which it was founded—namely, the advancement of zoology and animal physiology. Attitudes resulting from a confused interpretation of this purpose are undoubtedly to blame for some serious public misunderstandings about the nature of the Fellowship.

Scientific Activities of the Society

But however prevalent the misunderstanding, the Society has at no time failed to discharge the obligations of its charter. The Library which was started in 1835 is now one of the finest collections of zoological literature in the world. A Museum begun even earlier provided a valuable part of the early collections of the British Museum (Natural History). Regular scientific meetings have been held uninterruptedly ever since 1827, the Society taking over from the Zoological Club of the Linnean Society, which was then dissolved, as a national forum for zoological discussion. The leading zoologists of Britain have always contributed to these meetings, some of which, for example the famous meeting which in 1919 considered the phylogenetic and taxonomic status of *Tarsius*, are part of the general history of zoological science. The *Proceedings* of the Society, which now appears eight times a year, began in 1830, and the first part of the *Transactions* of the Society appeared in 1833. Both have been issued uninterruptedly ever since. Since 1886, the Society has also been responsible, for a time in association with the Royal Society, for the publication of the "Zoological Record", which had been started in 1864 by a group of zoologists connected with the British Museum.

In addition to this normal pattern of discussion and publication, which applies to all scientific societies, the Zoological Society has always been somewhat more directly concerned with the advance of zoology both through the work of its officials, and through the provision of anatomical and pathological material to research workers in other institutions. This contribution appeared more conspicuous in the nineteenth and earlier part of the present century, when the total volume of zoological research was far less than it is to-day, and when its emphasis was largely morphological and taxonomic. With the recent establishment of a new Veterinary Hospital and Pathology Department, the standards of animal husbandry in the Society's menageries, as measured by the decline in mortality-rates and an increase in birth-rates, are now improving fast. To-day both indices stand at record levels in the Society's history. The provision of new laboratory facilities will undoubtedly strengthen the direct part which the Society can play in the future advance of zoological science.

Educational Activities of the Society

These activities represent one of the two ways in which the Society discharges its obligation to advance the science of zoology. The other is the encouragement of zoological education, primarily, of course, through the maintenance of animal collections which, excluding fish and invertebrates, to-day constitute nearly 1,200 species or subspecies. The Society's menageries provide a far better picture of the range of the animal kingdom than, so far as is known, any other zoological collection in the world.

In co-operation with the educational authorities of the Greater London area, and with the help of the Nuffield Foundation, the Council, two years ago, established regular courses for school-children up to and including the sixth form. These have proved very popular, and a number of schools are now including the lecture-demonstrations as a normal part of their teaching time-table. In the previous year, the Society had established, jointly with the Granada T.V. Network, a full-time Television and Film Unit, the main effort of which now is the preparation of a series of films representing different aspects of animal life. This venture should add greatly to the Society's educational potential, as will also a Young Zoologists Club, founded early this year, and which has already attracted more than 1,300 members.

New Subscription Rates

The Council is confident that the reform in the structure of the Society made possible by the new by-laws will not only lead to an increase in the net revenue from Fellows, but will also powerfully reinforce the scientific strength of the Fellowship. Until this year the subscription of a Fellow had remained unchanged at £3 for well over one hundred years, and was incommensurately low in relation to privileges which potentially could be demanded in return. But unlike what prevails in almost every other scientific society, a Fellow did not obtain the published *Proceedings* of the Society as of right. Many professional zoologists who were unable to attend meetings, and who were uninterested in other rights of subscribers, could scarcely, therefore, see how membership helped develop their own science. Equally, they found it difficult to see how in such circumstances they could assist the Society in achieving its purpose. Raising the subscription of Ordinary Fellows to a realistic level had, therefore, to be reconciled with the certainty that very few scientists or teachers would belong to the Society at all if their subscription was not kept within the normal range of other scientific bodies. The 1958 by-laws have achieved the necessary compromise. Scientific Fellows now subscribe £4 and receive the *Proceedings*; while Ordinary (non-professional) Fellows subscribe £8 a year, without receiving the Society's scientific publications. Non-voting Associates continue to pay the old 1832 subscription of £3. While not deterring non-professional patrons of zoology, these changes will, it is anticipated, lead to a powerful recruitment of professional research workers and teachers of zoology.

Building Plans

By coincidence, the decision of the Appeal Court that these changes in the structure of the Fellowship had been validly confirmed by the Society was announced almost simultaneously with the publication of plans for the rebuilding and re-landscaping of the Regent's Park Gardens. The main purpose of the new plans, which have been devised by Sir Hugh Casson and Mr. F. A. Stengelhofen, is threefold. First, they provide modern accommodation for the animals; secondly, they improve public amenities and facilitate the circulation of visitors; and thirdly, they improve the Zoo æsthetically, by a more spacious and yet cohesive lay-out. The pre-requisite of a flexible master-plan was the need to achieve an initial degree of mobility by clearing at least one big site in an already overcrowded area. This will be accomplished in about a year's time, when the building of a new Works and Supplies Department, which is now being erected, is completed. The area at present being occupied by the Works Department will then be developed as paddocks for deer and antelopes, and the present quarters of these animals will in turn be adapted for elephants. From then on the plan should unfold smoothly.

The first step in planning was, of course, to define a general policy about animal collections. The decision was that a zoo in the metropolis should avoid expensive duplication and should contain, for educational purposes, as representative a series of the more important types of animal as can be got together. The aim, therefore, is to have in Regent's Park a collection the value of which is measured not by the number of its individual exhibits, but by the extent to which it represents the animal kingdom. In achieving this policy, the Society has the enormous advantage that since 1931 it has also owned Whipsnade Park, which covers more than 500 acres, and where the Society can help play a part in projects of animal conservation, such, for example, as keeping in existence species (for example, the Père David deer) that have already disappeared in the wild.

While these and other basic considerations were in process of decision, detailed consultations were started with the Ministry of Works and the Commissioners of the Crown Estate, who are the Society's landlords in Regent's Park. The new plan not only has their general approval, but also that of the London County Council and the Royal Fine Arts Commission. The larger part of the Zoo is on the south side of the Outer Circle. The main gate by which it is entered is being moved in such a way that the visitor of to-morrow will see down broad steps into a 'square' from which he can look around the Zoo and also into the Park beyond. At the same time, the Zoo and the Park will be landscaped so that their natural features are continuous on either side of a water-barrier which will mark the boundary between the two. Within the Zoo different areas will have distinctive characters, and will be connected by elevated walkways. The north gate will be moved to a more central position near a new bridge, and the banks of the canal, which separate the north from the middle garden, will be used, wherever possible, as grazing paddocks. The scientific and educational buildings will also be increased in size.

Fortunately, the first three years of rebuilding can be paid for out of funds which accumulated during the post-war period, when building restrictions made it impossible to carry out any reconstruction, and when large crowds visited the Regent's Park Gardens partly because of restrictions on motoring, and partly because of the relative lack of other public attractions. But in due course new sources of revenue will have to be found. The Society does not get any subsidy from public funds, except indirectly, in so far as the rent it pays for the Crown land it occupies has not increased for more than a hundred years. Almost every other big national or civic zoo in the world is subsidized. For example, the New York Zoo receives annually from the New York municipal authorities a sum that almost equals the total revenue which the Zoological Society of London has to earn. Other American zoos are also supported by their city governments. Most of the German zoos are municipal zoos which were reconstructed after the War out of public money. The Paris zoo depends for support on the Ministry of Education. The complete fulfilment of the plan for the Regent's Park Gardens will almost certainly need sources of revenue additional to that provided by the public at the gates.

Wherever the money comes from, the present plan of rebuilding is not some visionary scheme for an undefined future. It is a programme of redevelopment that is already being pursued. It is a plan, too, the implementation of which coincides with the first major change that has been made in the structure of the Fellowship since the Society's foundation 130 years ago. This change re-emphasizes the scientific and educational purpose for which the Society exists. In 1841, when the Regent's Park Gardens were managed largely as a private venture for private enjoyment, the following resolution was passed at a general meeting by an overwhelming majority: "The Society cannot divest itself of the scientific character so essential to its dignity and respectability without violating the Charter of Incorporation". The sense of this resolution is far truer to-day, when the management of the Society constitutes a trust that can be vested only in those who have the necessary knowledge to discharge the scientific and educational purposes of the Charter, and also the official or business standing commensurate with the responsibilities which the Society carries on behalf of the public.

SHOREWARDS UPSLOPE OF THE LAYER OF MINIMUM OXYGEN OFF BOMBAY: ITS INFLUENCE ON MARINE BIOLOGY, ESPECIALLY FISHERIES

By Dr. J. N. CARRUTHERS
National Institute of Oceanography,
Wormley, Godalming, Surrey

S. S. GOGATE
Central Marine Fisheries Research
Station, Bombay

J. R. NAIDU
Institute of Science, Bombay

AND

T. LAEVASTU
Fisheries Biology Branch, Food and
Agriculture Organization, Rome

Earlier Knowledge of Upwelling in the Arabian Sea

THERE are two factors of particularly great interest in the Arabian Sea: the seasonal upwelling caused by the prevailing monsoons and their changes, and the well-developed tropical subsurface layer of minimum oxygen. Both have pronounced effects on marine biology and especially on the seasonal nature of the local fisheries.

Upwellings along the Somali and South Arabian coasts and also around the southern tip of Ceylon during the south-west monsoon were indicated by Schott[1] on the basis of low surface temperatures then prevailing there. Upwelling could be expected to exist along the Bombay continental shelf during the north-east monsoon, and Jayaraman and Gogate[2] have earlier found indications which probably attest such between 20° and 22° N. latitude along this coast. Their conclusion was also based on the distribution of temperature and salinity there.

Layer of Minimum Oxygen

The tropical subsurface layer of minimum oxygen in the Arabian Sea has been described in reports devoted to the *John Murray* expedition of 1933–34. Of all tropical seas the layer of minimum oxygen is most pronounced in the Arabian Sea, where the oxygen content is nearly nil at its mid-depth. The upper boundary of the layer is relatively sharp and coincides with the sharp thermocline or is slightly below it. The depth of the thermocline varies seasonally, dependent upon the seasonal upwelling or the coastal piling-up of the surface waters according to the prevailing monsoon. According to Schott[1], the layer of minimum oxygen is most pronounced off Bombay, where it is found generally at the depth of 50 metres.

Most usually it is found in the northern part of the Arabian Sea at the depth of 75 metres, but towards the equator it descends to reach a depth of about 150 metres. Salinity within the layer is relatively high, being in the north around 36 per mille and in the central Arabian Sea about 35·5 per mille with temperature at 22–23° C. It is noteworthy that the salinity maximum is found slightly below the layer of minimum oxygen. Gilson[3] found a high nitrite content in the layer of minimum oxygen, and immediately above it a high concentration of plankton was recorded.

The layer in question cannot fail to have a pronounced effect on marine life. It is to be expected that where it runs into the contour of the continental shelf, very little if any animal life will be possible beneath. Furthermore, in the event of upwelling raising the layer of minimum oxygen, animal life in the water above will be endangered. Proof of this has been recorded on several occasions. There is an area in the southern part of the Arabian Sea, between long. 60–65° E. and lat. 6–12° N., where mass mortalities of pelagic fish have often been reported during the month of June. This area being a divergence area of winds and of the drift currents caused by them (it is actually the centre of a gyral), upwelling of the layer of minimum oxygen there is to be expected. Mass mortality of fish has also been reported along the Arabian and Indian coasts in areas and seasons where and when upwelling of the layer is to be expected. Such mass mortalities might very well be caused by the upwelling of the layer of minimum oxygen alone or in conjunction with the accompanying 'red tides'.

Investigations off Bombay during October–November 1958

Some modest investigations were made off Bombay during the latter part of October and the beginning of November 1958 by the personnel of a refresher course in marine biology sponsored by the United Nations Educational, Scientific and Cultural Organization. Because the north-east monsoon starts in October, an accompanying upwelling of the layer of minimum oxygen along this coast should be expected then because of the direction of the wind. This was in fact found, the layer with an average oxygen content of 0·7 ml./l. occurring at an average depth of about 18 m. some 18 nautical miles out from the coast. The slope of the discontinuity layer was upwards towards the coast (Figs. 1–3). The salinity in this layer of minimum oxygen was about 36·0 per mille and the temperature around 24° C. The phosphate content was also relatively high (greater than 1 µgm. at./litre). In a zone 7–10 nautical miles from the coast, the layer of minimum oxygen practically reached the surface. The oxygen content there was very low from surface to bottom (see Station 4). An intensive mixing by tides takes place in this zone, where the water was found to be rather turbid. Inshore of it there was coastal water which was also thoroughly mixed by the tides and which contained higher amounts of oxygen. This coastal water was extremely muddy because of the intensive tidal mixing and the soft nature of the bottom. Pronounced colour changes were noticed in the water. Near the coast it was brownish grey out to about 7 miles offshore. Seawards of this for some 3 miles the hue was greenish-grey. Still farther out the colour of the water graded into blue. Because the effects of the upwelling in

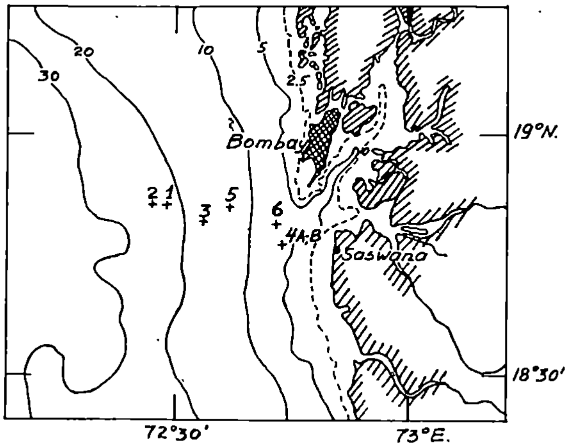

Fig. 1. Depth contours (in fathoms) and position of stations off Bombay

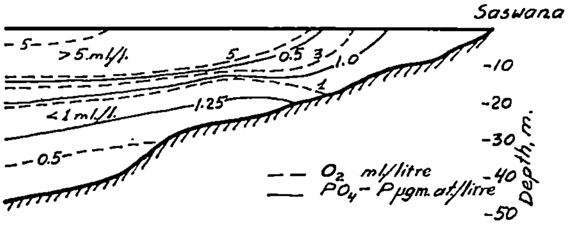

Fig. 3. Distribution of dissolved oxygen (ml./l.) and phosphate phosphorus (µgm. at./l.) off Bombay (beginning of November 1958)

respect of high salinity and high plankton production were detectable as far out as our Station 3 (17 miles offshore), the 10-mile-wide belt of water outside Station 4 (itself 7 miles from the coast) could be regarded as the 'upwelling and mixing zone'.

The layer of minimum oxygen shallows up the continental slope and intersects the bottom at about 7 fathoms depth. In consequence, demersal fish are forced to migrate shorewards during the upward movement of the layer. This results in notable concentrations of fish during the period October–December between the 'upwelling and mixing zone' (see Fig. 2) and the 'coastal zone' at about 13 miles out from Bombay harbour, that is, about 7 miles offshore from Saswan along the line of stations. Seawards of the upwelling and mixing zone there was a warm surface layer with relatively high phosphate and high oxygen contents. The upper boundary of the layer of minimum oxygen seems to rise and fall with the tides (see the observations from Stations 4*A* and 4*B* in the accompanying tables). This can be expected to cause up-and-down migrations of the fish concentrated in the area where the layer of minimum oxygen intersects the bottom contour. These vertical fish movements are known to the local bag-net fishermen. An abundant growth of plankton was found in the 'upwelling and mixing zone' which is likely to exhaust the nutrients from the surface layer rather quickly, and in fact a decreasing phosphate content was found going offshore. Also the oxygen content of the upper surface water showed a decrease farther offshore, which might be ascribed to the consumption of oxygen due to the decomposition of the organic matter produced in the upwelling and mixing zone and in its vicinity. Both the decrease of nutrient content in the surface layer and the downwards sloping of the thermocline and layer of minimum oxygen will probably continue as one goes farther offshore. Gilson[3] found in December and January off Bombay (at the edge of the continental slope) that the thickness of the surface layer was 50–60 metres and that it was completely depleted of nutrients.

The bulk of the standing crop of plankton was found above the discontinuity layer. The main phytoplankton organisms were: *Coscinodiscus*, *Trichodesmina* and *Ceratium* species. Of zooplanktonts the chief were copepods and sagittas. Scarcely any benthic animals were found in the depths where the oxygen content of the bottom water was less than 0·5 ml. per litre. In shallow water, benthos consisted mainly of hermit crabs, *Jibia curba* shells and a few nereid and polychaete worms.

The seasonal upwelling and the associated up-and-down movement of the layer of minimum oxygen caused by the changing monsoons have various important effects on the local fisheries. During the south-west monsoon the surface mixed layer will be rather thick and the layer of minimum oxygen correspondingly deep in the water off Bombay due to the piling up of surface waters. During the north-east monsoon the layer of minimum oxygen will gradually ascend into shallower depths because the surface waters will be blown seawards, so causing upwelling from below. The demersal fish which were distributed during the south-west monsoon over a large area on the relatively shallow continental shelf off Bombay will have to move into shallow water to escape lethal low-oxygen conditions. This chain of events will lead to the occurrence in shallow water during the north-east monsoon of fish concentrations easily available to the local fishermen and, in fact, there was a glut of landings soon after the start of the north-east monsoon in 1958.

The upwelling during the north-east monsoon causes also a high production of plankton off the Bombay coast, because nutrient-rich water is brought close to the surface, and it is naturally expected that pelagic fish would migrate into this area to feed on the rich standing crop of plankton then existing there. However, *Rastrelliger*, tunas, and Indian oil sardines do not come close to the coast in the Bombay area. It seems that these pelagic fish remain outside the 'upwelling and mixing zone' because of the low oxygen content of its water. Schools of pelagic fish were in fact sited at about 25 nautical miles off Bombay at the time to which this report relates.

The origin of the layer of minimum oxygen in the Arabian Sea is not yet fully understood, but it is associated with high salinities and relatively high temperatures, and several authors believe that it originates through the outflow of the Red Sea and Persian Gulf waters.

The seasonal behaviour of the surface layers of the Arabian Sea is not fully known. It would also be interesting to know the changes in intensity of the upwelling off Bombay during the north-east monsoon. From January onwards, the north-east monsoon turns along the Indian Coast to north and north-west. This turning might cause considerable changes in the conditions to be found during October–November and described above for the period here concerned.

Currents

Very obviously it would help greatly in the understanding of the oceanographical situations discussed above if it were possible to make observations of the speed and direction of the bottom water movements at regular and frequent intervals around the clock—say, every half-hour for a lunar day on a number of separated occasions. We had certain suitable apparatus of great simplicity for making such current observations, but time did not serve. Only a few spot observations were possible using the very simple instruments developed by one of us (J. N. C.), but a notable current one-third knot in speed was measured running towards about 210° magnetic. This was at the position lat. 18° 51′ N., long. 72° 29′ E., and served to show at least that the bottom water was not setting constantly towards the coast at the time. Perhaps it might have been found to set dominantly shorewards later after the north-east monsoon had become more strongly established. If so (and the matter should certainly be investigated), a mechanism explaining the shorewards uptilt of the layer of minimum oxygen would be to hand.

We wish to thank the participants in the refresher course in marine biology who were engaged in the collection of the observations; the Indian Navy for the provision of shipboard facilities, and Mr. K. Koli, who kindly allowed us to use his boat.

RUSSIAN CONTRIBUTIONS TO THE INTERNATIONAL GEOPHYSICAL YEAR

THERE are eighty-six scientific institutions in the Soviet Union taking part in the programme of the International Geophysical Year. They are organized by eighteen departments and ministries of which the most important are the Academy of Sciences, the Northern Sea Route Administration, the Hydrometeorological Service, and the Ministries of High Schools and Communication. The Soviet International Geophysical Year Committee publishes regularly an Information Bulletin giving details of the Russian investigations. It has also issued a bibliography of International Geophysical Year publications, arranged the issue of a series of commemorative postage stamps, and is preparing a full-length popular scientific film in colour dealing with its contributions to the International Geophysical Year.

Antarctica

Particular attention has been given to Antarctic research. The Academy of Sciences set up an Antarctic Expedition in 1955 and has established three main stations: Mirny (near Haswell Island), Vostock (near the south magnetic pole), and Sovietskaya (near the pole of relative inaccessibility). The two inland stations are more than 1,400 km. from the coast. There are also at present three further research bases. The Mirny Observatory carries out regular observations in nearly all the fields of the International Geophysical Year programme, such as meteorology, glaciology, oceanography, geomagnetism, ionospheric physics, seismology, and the study of cosmic rays and of Earth currents. The other stations are run on more modest lines.

A magnetic profile was made from Mirny to Pionerskaya, and from this the existence of a mountain ridge under the ice 250 km. from the coast was inferred. This was confirmed by seismic and gravimetric investigations, which showed that the ice is 2,500 m. thick in some places, and that substantial parts of the ground beneath the ice are below sea-level.

It was established that the Antarctic ice cap is shrinking, like that of the Arctic, but at a very much slower rate. The variation of temperature with depth in rocks was investigated, and in certain inland regions they were found to be frozen (that is, below 0° C.) to a depth of 200–300 m. Frozen rocks were found to thaw to depths of 0·1–2·0 m. in summer.

Geologists studied the coastal region between 80° and 110° E. Exposed rocks are scarce there, and mainly old pre-Cambrian crystalline schist and gneiss, intersected by vast granite intrusions, were found. This confirms the theory that this region is part of a shield. Metamorphosed sands and conglomerates were also found in this region.

An air survey was made of the coastline between 40° and 166° E., and maps have been published of this area. Three expeditions studied ocean currents, using the electromagnetic methods of measurement, and sedimentation and bottom structure, in a large part of the Antarctic Ocean.

The Arctic

In the Arctic, too, there has been a great deal of activity, particularly on the drifting ice stations. It was found that in summer, atmospheric pressure is abnormally low in the central Arctic and this disrupts the normal ice drift. It was also found that the ozone concentration is very great in March. A comparatively deep marine trench (up to 3,000 m.) was found between Greenland and Spitsbergen, which is of importance in the flow between the central polar basin and the North Atlantic.

Oceanography

The non-magnetic ship *Zarya* voyaged extensively (including a trip from Leningrad to Indonesia, crossing the Atlantic six times and visiting Australia via

Cape Town), and found anomalies even in the deep ocean, and determined the present position of the magnetic equator. The oceanographic ship *Vityaz* spent much time in the Pacific studying currents. It determined the boundary of the sub-arctic front between the Kuroshio and Oyashio currents, of the subtropical front between the Northern Trade drift and the North Pacific drift, and of the north (and south) tropical fronts between the Northern (and Southern) Trade drifts and the intertrade back drift. It found velocities of as much as 10–12 cm./sec. at 1,000 m. in certain places (instead of an anticipated maximum of about 3 cm./sec.). A new trench was found north of the Fiji Islands, and a part of the Marianas Trench was found to have the record depth of 10,990 m. Photographs of the ocean bottom were taken at depths of up to 9,800 m.

Rockets and Earth Satellites

By June 1, 1958, three satellites had been put into orbit and fifty-nine rockets fired, including one which reached a height of 473 km. From readings transmitted by the rockets the air pressure up to 260 km. was determined—at 260 km. it is of the order of 10^{-7} mm. mercury. A mass-spectrometer was taken up and it was found that, between 105 km. and 206 km., the main ions present have a mass number 30 (which is interpreted as NO ions). Dispersion interferometers were also taken up to measure the electron concentration in the ionosphere. It was confirmed that there is no clear layer at an altitude of about 110 km. but merely a region of maximum concentration of electrons. Beyond this the concentration of electrons falls slightly, and then increases to the *F*-layer, beyond which, contrary to the American observations, only a slow decrease was found. Animals were sent up in some of the rockets. They were recovered by parachute, and some of the animals made many trips. In the second satellite an animal was carried, and was found to behave normally in a state of free fall, and to manage well with other peculiarities of cosmic flight, during the week in which the air-regenerating apparatus was functioning. Ionospheric measurements made with the satellites confirm the results obtained with rockets. Observations of cosmic rays were obtained by means of the satellites; their intensities differed from the predictions of the present theories about the Earth's magnetic field. From the orbits of the satellites the density of the air layers through which they were passing was calculated, and found in some cases to be several times larger than the predicted values.

The third satellite was a veritable cosmic laboratory. It could measure the number and energy of micrometeorites hitting it, and carried a mass spectrometer. It measured its own electric charge, and the charges of the layers it passed through. It registered the atmospheric density and pressure, and carried a self-orientating magnetometer. It was also used for experiments on the control of orientation and internal temperature of the satellite vehicle.

Zodiacal Light, Meteorites and Earth Currents

An expedition to Egypt was organized to observe the zodiacal light and the polarization of the daytime sky, with specially developed instruments. These observations are being continued by the Helwan Observatory of the University of Cairo. The zodiacal light is also being studied at Aksenger, near Alma-Ata, in the U.S.S.R. (44° N., 76° E.), and by comparing these observations with those from Egypt it will be possible to find out how the properties of the zodiacal light depend on the ecliptical latitude.

In the U.S.S.R. eight stations have used radar to observe meteoric activity, and several formerly unrecorded streams of meteors were found, on January 15 and 16, 1958, for example, and on February 14 and March 9–15 of the same year. It was found that most sporadic meteors have elliptical orbits around the Sun, but some (less than 1 per cent of the whole) have been found which are definitely in hyperbolic orbits.

Earth-currents have been recorded continuously and pulsations of periods 1–4 sec. have been observed to occur simultaneously in the Arctic, Antarctic and middle latitudes. In the Antarctic large fluctuations occur in the amplitudes of the Earth potentials, up to about 1 volt/km.

Seismology

Seismic observatories were set up in the polar regions. There were six stations in the Arctic, and two in the Antarctic. These stations, in regions in which regular earthquake observations do not usually occur, give valuable information. The Antarctic stations observed about 600 earthquakes (in the two-year period beginning June 1, 1956), of which about 70 had epicentres south of 40° S.—however, no earthquakes have been detected which originated within the Antarctic mainland.

Microseisms were studied by many stations in the U.S.S.R. It was found that the microseisms observed in the European part of Russia originate mainly on the shores of Norway—no microseisms are observed when the storms are in the North Atlantic or on the shores of Greenland.

Okhotsk Sea—Pacific Ocean Structure

The crustal structure near the eastern coast of the U.S.S.R. was intensively studied. This region, extending to Kamchatka and the Kuril Islands, is of great interest. It has a high seismicity, with many shocks at all depths—this means that there is probably a deep major fault under the region. The deep seismic sounding method was used extensively; 3,300 km. of seismic profiles were taken at sea. The preliminary results show that the crust has different structures under the Okhotsk Sea, the Kuril Islands, and the oceanic plateau, with a thickening of the crust under the islands, and a substantial decrease of thickness under the oceanic plateau, where the crust is 12–18 km. thick (including the depth of the water). This region was covered also by aeromagnetic and sea gravitational surveys, and large anomalies were found (about 4,500 km. of sea gravitational surveys were taken).

The U.S.S.R. organizes the World Data Centre *B* for the International Geophysical Year: this has the task of collecting, keeping, and circulating data and results of all aspects of the work. Anyone wanting copies of such information should write either to Centre *B*1, Institute of Aeroclimatology, 33/35 Ulitsa Vorovskogo, Moscow; or Centre *B*2, Institute of Terrestrial Magnetism, 64 Chkalov Street, Moscow.

N. A. ROUTLEDGE

OBITUARIES

Prof. Wolfgang E. Pauli, For.Mem.R.S.

Unexpectedly to all but those near him at the time, Wolfgang Pauli died on December 15, 1958, at the early age of fifty-eight.

Born in Vienna, Pauli graduated in Munich, and worked successively at Göttingen, Copenhagen and Hamburg. Nowadays, however, his name is mainly associated with Zurich, where he was professor of theoretical physics at the Federal School of Technology for the past thirty years, broken only by five years in Princeton during the Second World War.

Though Pauli died so young, it is no exaggeration to say that he was one of the leaders of theoretical physics throughout the past forty years. At the age of nineteen he was commissioned by his teacher, Arnold Sommerfeld, to write the article on relativity for the "Enzyklopædie der Mathematischen Wissenschaften". At that time, general relativity was novel and its literature scattered and understood by few. The young Pauli succeeded in presenting the entire subject in a work which was immediately recognized as masterly and which, in its scholarly precision, remains unsurpassed to this day.

Having demonstrated so early the depth and clarity of his insight into physical theory, Pauli did not take long to prove that as an originator of new ideas he was equal to the greatest. In 1924 he enunciated his 'exclusion principle' in terms of which so much of the then existing knowledge of atomic structure fell into order : we owe to Pauli the introduction of the two-valued variable required to characterize completely the state of an electron, and when, in 1925, Goudsmit and Uhlenbeck took the important step of interpreting their variable as an intrinsic angular momentum, it was Pauli again who showed how this concept could be consistently incorporated into the scheme of quantum mechanics and how the exclusion principle could then be formulated definitively as a symmetry requirement satisfied by the wave function of an atomic system. This also became the basis of the powerful concept of the Fermi statistics governing the behaviour of electrons. In 1945 Pauli was awarded the Nobel Prize for Physics, primarily for these achievements.

Though the nineteen-twenties undoubtedly represented a peak in Pauli's creative work, he in fact never ceased to produce work of comparable depth and to exert a profound influence on the development of physics. He continued both to bring forth new ideas and to clarify and consolidate the ideas of others. It was Pauli who, in an informal letter, first threw out the suggestion that an unknown, uncharged and massless particle was emitted in every radioactive β-disintegration. This entity, to which Fermi gave the name 'neutrino', to-day has an assured and important place in our picture of Nature.

We can only name a few of Pauli's great contributions to theoretical physics. With Jordan and with Heisenberg he laid the foundations of the quantum theory of fields, a subject still very much the concern of pioneering theorists, and when after 1945 great advances were made in this domain, mostly by physicists of the younger generation, Pauli, almost alone among the founders of quantum theory, participated directly in these developments. Previously, in 1940, he had firmly laid one cornerstone of field theory, by giving a proof of the long-conjectured relation between the spin and the 'statistics' of any elementary particle. This result, so closely related to his great work of the 'twenties, gave Pauli himself particularly great satisfaction.

Pauli's writings are in daily use among research workers everywhere. Perhaps the work most greatly admired is his article on the principles of wave mechanics in the "Handbuch der Physik", Vol. 24, 1933. Younger theorists may perhaps not realize how much the orientation and emphasis of research to-day owe to the guidance given by Pauli in this and his many other writings.

Those whose good fortune it was to be close to Pauli at one period or another know how much more has been lost by Pauli's death than can be put into words. As a personality, no one more deserves to be described as unique. His rotund build and characteristic gait, his gestures and mannerisms, his sharp tongue and gleeful laugh will all be remembered vividly by his friends. Anecdotes around him abound, and the legend of the 'Pauli effect', spelling disaster to any apparatus he approached, is all but believed throughout the world.

When in personal contact with Pauli it was impossible to lose awareness of all his characteristics and of the sense of the extraordinary in his nature. As many of his students discovered, communication with him did not always come easily, least of all through formal lectures. But once one was drawn into discussion, the barrier was surmounted and the experience of sharing his thoughts became infinitely rewarding. Through his large correspondence he extended his influence far beyond his own Institute. With Pauli's death many a physicist has lost a guide and critic without equal.

Not all of us had the privilege of sharing his deeper thoughts on questions transcending his own science. In his later years particularly, his studies extended into the philosophical domain and a number of writings scattered at present but shortly to be published in a collected English edition testify to this.

All those who can look back to personal contact with Wolfgang Pauli feel a deep sense of loss. He will be remembered by all as a great scientist, an unforgettable personality and a sincere friend.

N. Kemmer

Prof. A. C. Pigou

During the first half of the twentieth century, the University of Cambridge had a galaxy of brilliant scholars, scientists and thinkers. Prof. Arthur Cecil Pigou was among the greatest of them, and by his death on March 7 the University, and in particular his College, King's, have suffered an irreparable loss.

Prof. Pigou will be remembered by economists so long as the development of their science is studied. The favourite pupil of the great Marshall, and chosen by Marshall to be his successor in the chair of political economy, Prof. Pigou built on the foundations which Marshall had laid. By his teaching, his books, his articles in economic and other journals, his membership of Royal Commissions, and his letters in *The Times*, he played a major part in winning for economists the wide authority which they have to-day.

His most important work, "The Economics of Welfare", went through many editions, and was translated into many languages; it became, indeed, like his "Study in Public Finance" and his "Theory of Unemployment", a standard text-book in most schools of political economy throughout the world.

His title, "The Economics of Welfare", illustrates admirably his basic approach to his subject. In his introduction to the first version of his short book on "The Political Economy of War", he described it further; speaking of the "extraordinarily complex system of exchange built round the motive of private money profit", which it was his life's task to analyse, he described the "grave flaws of this system; it involves great waste; it has meant for very many human beings weariness, discontent, hunger and pain". The economists' hope, he said, was "that by carrying out well and truly this task of positive analysis, this economic anatomy and physiology, they might help other men, better trained than themselves for the practical work of government and administration, to fashion remedies or palliatives for the many evils they descry". He would never 'talk shop', if he could possibly avoid it; but those who were fortunate enough to have him as their teacher soon learnt the warm but practical idealism by which he was inspired.

They learnt, too, the splendid simplicity of his character, and the complete, uncompromising integrity of his heart and mind. Some of them, especially those with whom he climbed the rocks of Cumberland, and the mountains of Switzerland, Austria and Norway, came to know his unique gift for friendship, and his courageous determination as a leader, whatever the difficulties with which he met. In 1925, when he was only forty-seven, he strained his heart by climbing two peaks in the Alps in one morning, before he was fully trained; in spite of this 'fibulation', a week later he completed a long, unknown and difficult climb, only to collapse when he had brought his party safely off the rocks; from that point he was transported to his hotel on mule-back; yet only a week after that he accomplished what was, perhaps, his most difficult lead up the face of the Aiguille de la Za, circumventing an iced-up chimney by a route that could only be classed as exceptionally severe. It was a great climb; but the 'fibulation' which he then defied ultimately undermined his health, and brought his mountaineering to an untimely end.

Pigou was extremely shy with strangers—unless they were under ten years old. But when a little boy of five accomplished a walk at Buttermere over Scarth Gap and the Haystacks, and back by the Miners' path, Pigou was so moved by admiration that he invited the five-year-old hero, *and* his parents, to tea in his lovely house, Lower Gatesgarth.

There are many of his Cambridge friends to whom King's, without him, will never seem the same. King's was, indeed, a perfect setting for a life of such blameless goodness, and of such eminent academic and practical achievement. Those who were at Cambridge before the First World War will remember the warmth and power of his eloquence in Union debates, and his vivid interest in philosophy and poetry. Everyone who knew him will remember how he despised and hated the senseless folly of war. The epilogue to the second version of his "Political Economy of War", written in 1939, has the passion and the moving eloquence of the Gettysburg oration: "We are at a start of a journey whose end we cannot foresee. Yet once again the young and gallant, our children and our friends, go down into the pit that others have digged for them. Yet once again men of greater age, we that, if it might be, would so gladly give for theirs our withered lives, we cumber the earth in vain. We wait and watch and—those who can—we pray. As an economist I have not the power, nor, as a man, the heart, to strain through a night so black to a dawn I shall not see".

Cambridge will see no more his erect and striking figure walking along the Backs; but it will be long before the memory of his noble spirit has passed away.

Philip Noel-Baker

NEWS and VIEWS

Imperial Chemical Industries, Ltd.: Sir Ewart Smith, F.R.S.

Sir Ewart Smith, who is retiring from the board of Imperial Chemical Industries, Ltd., obtained first-class honours in the Mechanical Science Tripos at Cambridge. He joined Synthetic Ammonia and Nitrates, Ltd. (later the Billingham Division of Imperial Chemical Industries, Ltd.), in 1923, and later played a part in the major development of the huge Billingham complex, becoming its chief engineer in 1932. He was seconded to the Ministry of Supply in 1942 to be chief engineer and superintendent of armament design. He returned to Imperial Chemical Industries, Ltd., in 1945, when he was appointed technical director, and was knighted for his war-time services in 1946.

Sir Ewart's responsibilities as technical director, and since 1955 as a deputy chairman of the Company, have not precluded his devoting a great deal of time and energy to other organizations. As a member of the British Productivity Council—he was its chairman in the early and difficult days following its formation—he has been nationally respected and admired by management and trade union leaders alike for his progressiveness, forthright honesty and vigorous leadership

Sir Ewart has also served on numerous other bodies, governmental and scientific, including the Advisory Council on Scientific Policy, the Committee on Scientific Manpower, the Northern Ireland Development Council, and as a vice-president of the Institution of Mechanical Engineers. He was elected a Fellow of the Royal Society in 1957 in recognition of his contribution to technology, and this year is president of Section G (Engineering) of the British Association. He is keenly interested in education, and is a governor of Christ's Hospital, his old school. Sir Ewart is to serve as chairman of the new council set up to assist the application of modern industrial techniques in the National Health Service.

National Science Foundation Antarctic Research Programme: A. P. Crary

Albert P. Crary has been appointed chief scientist of the newly established United States Antarctic research programme within the National Science

Foundation. Mr. Crary, a noted polar geophysicist, recently returned from two and a half years in Antarctica, where he was station scientific leader of the Little America Station and deputy chief scientist of the Antarctic programme of the U.S. National Committee for the International Geophysical Year. The United States Antarctic research programme has been established to co-ordinate the scientific efforts of Federal agencies with an interest in Antarctic research and to receive proposals by university scientists and independent investigators for polar research. The Foundation looks to the Committee on Polar Research of the National Academy of Sciences—National Research Council for recommendations regarding the desirability of proposed programmes. Mr. Crary will advise the Foundation in the planning of the scientific projects, selecting personnel and equipment, and will supervise the conduct of field investigations, data analysis, and publication. Mr. Thomas O. Jones is director of the Antarctic research programme of the National Science Foundation. Mr. Crary will maintain offices at the Foundation and at Cambridge, Mass., where he will continue his affiliation with the Geophysics Research Directorate, Air Force Cambridge Research Center.

Geography at Sheffield : Prof. C. A. Fisher

Mr. Charles Alfred Fisher, at present reader in geography in the University of Leicester, has been appointed to the chair of geography in the University of Sheffield in succession to Prof. D. L. Linton (see *Nature*, 182, 497; 1958). Mr. Fisher, who will take up his appointment in October, graduated at Cambridge with first-class honours in both parts of the Geographical Tripos. He was awarded a University Bartle Frere Research Exhibition in 1938 and for the next two years he undertook research at Cambridge. After nearly six years in the Army, Mr. Fisher took up an appointment in January 1946 as an assistant lecturer in geography at University College, Leicester, and later that year was appointed to a lectureship in geography at the University College of Wales, Aberystwyth, which he held until December 1949. Before returning to Leicester as a lecturer in 1951, Mr. Fisher held an appointment as senior research officer at the Institute of Colonial Studies, Oxford. In October 1958 the title of reader in geography in the University of Leicester was conferred on him.

In 1947 Mr. Fisher was awarded a Travelling Fellowship of the Royal Geographical Society which enabled him to make a series of study visits to Dutch universities and the Tropical Institute of Amsterdam in connexion with his researches on South-east Asia, and during the session 1953–54 he was a visiting lecturer in geography at Yale University, and was appointed Visiting Fellow of Trumbull College, Yale. Mr. Fisher has contributed chapters to several books and has published many articles on a wide range of geographical subjects, particularly on South-east Asia and the Far East.

Nuclear Technology at the Imperial College of Science and Technology, London

Courses of instruction and postgraduate research in the various branches of nuclear science and engineering given at the Imperial College of Science and Technology, London, include those on the theoretical and practical aspects of nuclear and high-energy physics (Physics and Mathematics Departments); a postgraduate course in nuclear power (Department of Mechanical Engineering); and a new course in nuclear technology (chemical) (Chemical Engineering Department). This one-year course, which commences in the session 1959–60, is under the supervision of Mr. G. R. Hall, reader in nuclear technology, assisted by Dr. H. D. Evans, Mr. S. Hartland and Dr. A. J. Swallow. In addition to topics relating to nuclear power production, such as fuel-element technology and the processing of irradiated fuels, a substantial part of the course will be devoted to the applications of radioisotopes as tracers and for non-destructive testing, and the possible uses of sources of radiation for inducing industrial-scale chemical reactions. Applications for admission should be made before June 1, on a form obtainable from the Registrar, Imperial College of Science and Technology, London, S.W.7.

Nuclear Training in the Biological Sciences in the United States

The United States Atomic Energy Commission has approved thirty-two new grants totalling 316,717 dollars to thirty-one American colleges and universities. These grants are part of a programme to assist colleges and universities to expand their facilities for training in radiation biology and in the use of radioisotopes in the fields of agriculture, veterinary medicine, medicine and pharmacy, public health and biology. The new grants bring to 1,810,707 dollars the total amount awarded in making 152 grants to 110 institutions since the Commission's programme was initiated in October 1957.

The Australian National University : Field Station for Astronomy

About a year ago the Department of Astronomy (Mount Stromlo Observatory of the Australian National University) initiated a survey to locate a suitable site for a field station. Excessive night cloudiness in Canberra and vicinity renders it impracticable to carry out at Mount Stromlo sustained long-range observational programmes. The intention is not to transfer major equipment from Mount Stromlo to the field station, but the University may want to place some future new equipment there rather than at Mount Stromlo. There is no question of transferring any of the research, teaching or administrative activities to the site of the field station. During the past year, tests for night cloudiness have been carried out at four localities, all of which are hill tops rising 700–1,000 ft. above the level of the surrounding plain, three in New South Wales and one in Victoria. According to the records gathered to date, Natimuk (Victoria) has the largest percentage of clear nights (65 per cent over 122 nights), Griffith has 54 per cent over 266 nights, Condobolin 47 per cent over 263 nights. Mount Stromlo had only 28 per cent clear over the same interval. Alectown and Lake Cargellico both show 40 per cent clear. All observations refer to the first half of the night.

Astronomical tests are to be initiated at various sites, notably near Natimuk, Griffith and Condobolin. Provided arrangements can be made for temporary occupation of the site, access roads, electricity supply and telephone service, a control station will be set up near Griffith and one of the smaller telescopes from Mount Stromlo Observatory will be moved there, with the intention of operating it for a period of eighteen months. Mobile telescopic equipment will be set up at the other sites under consideration, and each site will probably be occupied several times for periods of about two weeks at any one time.

Russian *Journal of Inorganic Chemistry*

STARTING with the January 1959 issue, the Chemical Society is to publish, with the support of the Department of Scientific and Industrial Research, a cover-to-cover translation of the monthly journal, *Zhurnal neorganicheskoi Khimii*, a publication of the Academy of Sciences of the U.S.S.R. The translation will be undertaken for the Society by Infosearch, Ltd., and the Society has appointed Prof. P. L. Robinson as executive editor. He will be assisted by an advisory panel of distinguished inorganic chemists. The sale and distribution of the journal will be undertaken by Cleaver-Hume Press, Ltd., 31 Wright's Lane, London, W.8, from whom a detailed prospectus giving the scope of this journal may be obtained. Translations will be issued in monthly parts as soon as possible after the Russian original is available. The subscription rate will be £30 (United States, 90 dollars) per annum, but universities and technical colleges may subscribe at a discount of 25 per cent. Single issues can be purchased at £4 (12 dollars) per copy. The Society also hopes to start the publication within the next year of translations of the Russian *Journal of Physical Chemistry* (*Zhurnal fizicheskoi Khimii*) and *Progress in Chemistry* (*Uspekhi Khimii*).

School Mathematics

USEFUL comments on the teaching of mathematics in schools are to be found in the Spring 1959 issue of *Forum* (**1**, No. 2). The headmaster of a junior school, the head of the mathematics department at a comprehensive school and a university professor of mathematics all agree that the aversion to mathematics which is found in so many intelligent adults was implanted in the primary school. According to one observer, mathematics in the primary school consists entirely of computation. "Available text-books present dreary, intelligible masses of sums instead of challenging children to think, to reflect on how, when and where, with numbers and space relationships." Instead of imparting an appreciation of number relationships in the way advocated by Piaget, most mathematics teaching in primary schools consists of a series of tricks which have little connexion with the life of the child. Suggestions for making the teaching more related to the child's experience are described in two of the articles, while Prof. R. L. Goodstein, of the University of Leicester, also advocates research to find a more enlivening syllabus and more successful methods of presentation.

Control of Exhaust Fumes

IN reply to a question in the House of Commons on March 24 regarding research into the control of the emission of diesel oil and petrol exhaust fumes from vehicles, Mr. H. Nicholls said that the results of work on combustion in diesel and petrol engines, carried out by the Motor Industry Research Association and the British Internal Combustion Engine Research Association and elsewhere, showed that the greater part of the smoke from such engines could be prevented by proper adjustment, running and maintenance. The Warren Spring Laboratory of the Department of Scientific and Industrial Research had tested a catalytic device which effectively reduced the pollution from petrol engine fumes. Mr. Nicholls agreed that unpleasant fumes were often due to absence of proper maintenance.

National Research Development Corporation of India

THE fourth annual report of the National Research Development Corporation of India, which includes the statement of accounts for the period ending March 31, 1958 (pp. 20. New Delhi: National Research Development Corporation of India, 1958), records 59 inventions reported for development by eighteen research institutions and individuals, making a total of 447. Five new patent applications were filed and seventeen new licence agreements were negotiated. New projects for refining cotton seed oil, for white cement from feldspar, and for a fluidized-bed technique for textile processing were instituted, and a project for pine oil from Indian turpentine was completed. Progress is reported in those for production of phthalic anhydride by fluidized-bed oxidation of coal tar oils, for copper chlorophyll, for bamboo mechanical pulp, the de-ionization of sugar cane juice and for a thermoelectric generator.

The Civic Trust

FOUNDED just over a year ago to ensure that community developments are made with good taste and dignity and to give delight to all inhabitants, the Civic Trust has already acquired a momentum which should lead to a future of promise and fulfilment. In collaboration with the B.B.C. Television Service, four useful films have been produced showing how the Trust is waging war on ugliness. The threatened demolition of part of the Close of Dunblane Cathedral has been averted by prompt intervention by the Trust. As the first of a series of 'live' experiments, Magdalen Street, Norwich, is being redecorated in accordance with an over-all scheme prepared by the Trust. The Trust is also to develop a system of amenity awards, the objects of which are to encourage good local architecture and building of all kinds which can be said to make a desirable contribution to the civic and rural scene as a whole, and to stimulate interest in all other types of physical development. Details of the awards can be obtained from the Civic Trust, 79 Buckingham Palace Road, London, S.W.1.

South Australian Museum

THE most recent issue of the *Records of the South Australian Museum* (13, No. 2; 1958) forms another sumptuous part of the current volume, with 156 pages of text and twenty-four excellent plates. Most of the papers are by members of the staff of the South Australian Museum and include contributions on the aboriginal cave paintings at Sleisbeck, a revision of the ghost moths, new cretaceous fossils from New Guinea, Australian beetle-mimicking bugs of the family Lygaeidae, and on the Potoroinea (a group of central Australian mammals). Such a publication gives evidence of a progressive museum with a staff undertaking research of a high order.

Aviation Psychology

THE military Air Forces and civilian air lines of every country are aware of the many psychological factors involved in safe flying, and of the difficulties in selecting and training suitable air-crew. But only in the United States and, to a lesser extent, in Britain are there sufficient psychologists employed in the field of aviation to develop a systematic attack on these problems. Thus in an attempt to co-ordinate and further their activities, the aviation psychologists of Western European countries have formed an association; and a recent monograph (Aviation

Psychology in Western-Europe and a Report on Studies of Pilot Proficiency Measurement. Publication No. 1 of the Western-European Association for Aviation Psychology. Pp. 64. Amsterdam: Swets and Zeutlinger, 1958. 15*s*.) contains a series of reports on the present position of their work from representatives of most of the countries concerned; the absence of British civilian air-line representatives is conspicuous. It is interesting to learn that most Air Forces or companies are achieving better selection of pilots by scientific testing (despite considerable variations in the relative emphasis placed on paper-and-pencil tests, apparatus tests and clinical assessments). But it is disappointing to find so little attention, outside the British Institute of Aviation Medicine, to 'human engineering' and training problems such as the effects of stress and fatigue on air-crew, and the design of aircraft equipment and simulators (synthetic training devices). Much the most stimulating paper is one contributed by the American psychologist, Dr. C. W. Bray, on the detailed recording of pilot performance.

Statistical Review of England and Wales for 1956

The Registrar General has recently issued the Commentary Volume on the Statistical Review of England and Wales for 1956 (pp. xvi+294. London: H.M. Stationery Office, 1958. 16*s*. 6*d*. net). As has become established practice, this volume includes some special analyses, as well as commentary on the vital events of the year to which it relates. There is included a nuptiality table for 1951–55, which has been computed in connexion with the fertility analysis of the 1951 census. Such a table is similar to a life-table, but shows the survivors at various ages up to fifty by marital status. The very high rates of marriage prevailing in 1951–55 are indicated by the fact that of 100,000 females, 90,656 survive to age fifty, of whom only 4,837 have never been married. Of the group of males surviving at age fifteen, only half are still single at twenty-five; in the case of females the corresponding age is twenty-two. Another special feature included is a comparison of causes of death as ascertained after autopsy with those given on death certificates. The comparison applies to deaths occurring in a number of selected hospitals, and deaths certified by general practitioners are not included. It is shown that in 19 per cent of all cases, new facts were ascertained by the pathologist which had not been reported by the clinician. It was also apparent that deaths from cancer of the lung were under-recorded, in spite of the greater diagnostic facilities that were available.

Insect Toxicologists' Information Service

At a meeting held during the tenth International Congress of Entomology at Montreal, insect toxicologists agreed to co-operate with Dr. D. Dresden of the University of Utrecht in establishing an Insect Toxicologists' Information Service. The first Bulletin of the information service was issued recently (Insect Toxicologists' Information Service, Bulletin No. 1. Pp. 106. Vondellaan 6, Utrecht, 1958) by Dr. Dresden. The object of the Service is to enable insect toxicologists all over the world to keep in touch with one another and to be kept up to date with each other's research activities. The Bulletin, which is to be issued annually, is designed for this purpose. The names of the workers on insect toxicology are given, with the laboratory in which they work and some indication of their interests. Some account is also given of the biological material that they work with, since interchange of material may facilitate research. The main body of the Bulletin consists of short notes from the workers themselves on the work they are doing, and it is necessary to submit these notes in order to receive a copy of the Bulletin. Providing the insect toxicologists fulfil their promise to co-operate with Dr. Dresden by submitting their notes regularly, this service should greatly benefit research in this field.

The Nessim Habif Prize

The University of Geneva will award in 1959 the Nessim Habif Prize of 10,000 Swiss francs to an author of a work or to an inventor who has made an important contribution to the knowledge or uses of plant cellulose or its synthetic derivatives. Manuscripts must be submitted by May 1 to the Doyen de la Faculté des Sciences de l'Université de Genève, Université, rue de Candolle, Genève, from whom further information can be obtained.

Harkness Fellowships of the Commonwealth Fund

The British Committee of Award of the Commonwealth Fund has announced the following elections, among others, to Harkness Fellowships for 1959, tenable for one or two years in the United States: R. H. Cassen (London School of Economics), economics; C. B. Cox (King's College, London), palæontology; R. N. Curnow (Aberdeen), biostatistics; V. J. Emery (Clare College, Cambridge), nuclear physics; C. W. J. Granger (Nottingham), economics; J. F. Hodgess Roper (Magdalen College, Oxford), international economics; S. C. Hunter (Armament Research and Development Establishment), theoretical mechanics; J. L. Jinks (Birmingham), genetics; A. D. McLachlan (Trinity College, Cambridge), theoretical chemistry; G. P. McNicol (Glasgow), medicine; W. T. Norris (Pembroke College, Cambridge), engineering; M. L. V. Pitteway (Queens' College, Cambridge), radio physics; D. C. Smith (Queen's College, Oxford), botany; J. B. Taylor (Atomic Weapons Research Establishment), theoretical physics.

International Oceanographic Congress

The American Association for the Advancement of Science is to hold an International Oceanographic Congress at the United Nations Building in New York, during August 31–September 12. The Congress is being planned in co-operation with the International Advisory Committee on Marine Sciences of Unesco and the Special Committee on Oceanic Research of the International Council of Scientific Unions. The Congress has the endorsement of the International Association of Physical Oceanography of the International Union of Geodesy and Geophysics. The programme has been designed to afford discussion among scientists interested in diverse fields of specialization within oceanography. Governments as well as universities and scientific organizations abroad are sending delegates to the Congress. It is also suggested that research vessels be sent to New York for the duration of the Congress, to make it possible to exhibit instruments used at sea and to display the most recent data and collections of biological and geological samples and chemical techniques. Further information can be obtained from the American Association for the Advancement of Science, 1515 Massachusetts Avenue, N.W., Washington 5, D.C.

Announcements

Prof. A. R. J. P. Ubbelohde, professor of thermodynamics at the Imperial College of Science and Technology, London, has been appointed director of the Salters' Institute of Industrial Chemistry on the retirement of Sir Alfred Egerton on June 30.

Allan Ray Putnam has been appointed managing director of the American Society for Metals, a new position established by the Board of Trustees following the death last May of William H. Eisenman, who was national secretary and executive head of the Society for forty years.

Mrs. Elwyn Davies, of Llandaff, Cardiff, who is a member of the Archæology and Art Committees of the National Museum of Wales and of the Board of Celtic Studies of the University of Wales, and Mr. John C. P. de Winton, of Brecon, have been appointed members of the National Parks Commission. Mrs. Davies will fill the vacancy left by the late Lady Hopkin Morris, and Mr. de Winton, who is a member of the Breconshire Education Authority, has been appointed as another representative of Welsh interests.

The following were recently elected as officers and members of Committee of the Society for the Bibliography of Natural History: *President*, Dr. J. Ramsbottom; *Hon. Secretary and Treasurer*, A. C. Townsend; *Committee*, G. F. Elliott, Dr. F. C. Fraser, F. J. Griffin, W. T. Stearn, C. K. Swann, Dr. D. W. Tucker.

The annual general meeting of the Antiquarian Horological Society will be held at the Science Museum, South Kensington, on May 1. The new honorary secretary of the Society is Mr. J. C. Stevens, 53 Woodfield Crescent, Ealing, W.5, from whom further information can be obtained.

A meeting will be held to consider a proposal that an International Congress on Corrosion be held in London in 1961 under the sponsorship of the Society of Chemical Industry. The meeting will be held at 14 Belgrave Square, London, S.W.1, at 3 p.m. on April 20, and all persons interested in the proposal are invited to attend.

The fifteenth Annual National Electronics Conference will be held at the Hotel Sherman, Chicago, during October 12–14. Abstracts, no longer than two hundred words, must be received by Mr. E. Van Valkenburg, Electrical Engineering Department, University of Illinois, Urbana, by May 1.

The second international conference on Medical Electronics will be held in the Unesco Building, Paris, during June 24–27. Further information can be obtained from Dr. C. N. Smyth, University College Hospital, Gower Street, London, W.C.1.

The twelfth Brookhaven Symposium in Biology, on Structure and Function of Genetic Elements, will be held during June 1–3. Sessions will be held on: structural aspects of nucleic acids; biochemical activities of nucleic acids; the gene; structure and duplication of chromosomes; nuclear–cytoplasmic relationships. Further information can be obtained from Dr. M. Levine, Brookhaven National Laboratory, Upton, New York.

The second symposium on X-ray Microscopy and X-ray Microanalysis will be held in Stockholm during June 15–17. The symposium will deal with new developments in X-ray microscopy and X-ray microanalysis as well as applications of these techniques. Further information can be obtained from Dr. G. Höglund, Institutionen för Medicinsk Fysik, Karolinska Institutet, Stockholm 60, Sweden.

The Italian National Committee for Nuclear Research is organizing a Congress on Nuclear Energy to be held in Rome during June 16–20, during the Sixth International Exhibition on Electronics and Atomic Energy. Further information can be obtained from the secretary of the Congress, Mr. Roberto Levi, Comitato Nazionale per le Ricerche Nucleari, Via Belisario 15, Rome.

The Advisory Group for Aeronautical Research and Development of Nato is holding a meeting on "Chemistry of Propellants" in the Nato Headquarters Building, Palais de Chaillot, Paris, during June 8–12. During the first four days the following themes will be developed: (1) properties and preparation of propellants; (2) theoretical and experimental performance evaluation; (3) fundamental studies; (4) sources, availability, and estimated costs of propellants. The fifth day will be devoted to a round-table discussion on "Basic Problems in Propulsion".

The European Conference for Industrial Management on "Industrial Prospects in Nuclear Energy", organized by the European Nuclear Energy Agency, will be held at the Palais des Congrès, Stresa, during May 11–14. There will be eight sessions, devoted respectively to a survey of European nuclear energy programmes; the economics of nuclear power; financing such programmes; legal problems involved; management problems; the market for materials; the market for equipment; and the market for instruments. Further information can be obtained from the Information Officer, European Nuclear Energy Agency, Organization for European Economic Co-operation, 38 Boulevard Suchet, Paris 16^{e}.

The Development Commissioners, in association with the Ministry of Agriculture, Fisheries and Food and the Scottish Home Department, are prepared to award postgraduate training grants in fishery research tenable from October 1, 1959. These grants are intended to enable selected candidates to undergo a specified course of training to fit them for the investigation of problems in marine or freshwater science. Candidates must be nominated by a senior member of a university department. Provisional applications will be accepted from candidates who have not yet sat their final examination or who have not yet been informed of the result. Further details and forms of application, returnable by May 20, can be obtained from the Secretary, Development Commission, 3 Dean's Yard, Westminster, London, S.W.1.

Cornell University annual summer Laboratory Course in Techniques and Applications of the Electron Microscope is to be held during June 15–July 3. The course is planned to meet the needs of senior research workers in the field of electron microscopy. Registrations will be limited in number, to provide ample facilities for the members to pursue extensive laboratory work in their special fields, at introductory or advanced levels depending on their previous experience. The course of lectures is designed to give members an intensive survey of basic theory, as well as interpretation of results and application to research problems. Further information and forms of application can be obtained from Prof. B. M. Siegel, Rockefeller Hall, Cornell University, Ithaca, New York.

HYPERSONIC FLOW

ON December 15, some two hundred representatives of the research establishments, the aircraft industry and the universities attended an all-day discussion on hypersonic flow sponsored by the Royal Aeronautical Society and held, under the chairmanship of Dr. G. W. H. Gardner (Royal Aircraft Establishment, Farnborough), in the rooms of the Institution of Mechanical Engineers.

An introductory paper surveying the problems of hypersonic aerodynamics was read by Mr. R. J. Monaghan (Royal Aircraft Establishment, Farnborough). The term 'hypersonic' can generally be applied to flight at Mach numbers greater than about 5, for it is at speeds of this order that the linearized equations of supersonic flow become inadequate, boundary layers of increased thicknesses begin to interact appreciably with flow fields around slender bodies and aerodynamic heating assumes major importance. A further boundary occurs at Mach numbers of the order of 8–9, when there is sufficient kinetic energy to provide some dissociation of the oxygen molecules in air, and the amount of dissociation increases with increasing Mach number above this value.

In designing for the alleviation of aerodynamic heating there are two distinct cases. The first relates to the uncontrolled re-entry of a freely falling body, for which a high-pressure drag shape is required; the second refers to sustained flight, for which a shape with low-pressure drag is probably better, radiation giving appreciable control of surface temperature. Low-pressure drag accords with design for aerodynamic efficiency and there is scope for research on three-dimensional lifting shapes.

The strong curved bow wave moving ahead of the body which is a characteristic of hypersonic speed implies that no real distinction can be drawn between blunt and sharp noses; moreover, the necessity for avoiding excessive rates of heat transfer means that the nose must be blunted. Some distinction can be made, however, between bodies in which the curvature varies slowly along the surface, and flat-faced bodies in which a distinct shoulder occurs.

In his paper on general characteristics of hypersonic flow fields, Dr. R. N. Cox (Armaments Research and Development Establishment, Fort Halstead) gave a historical survey of early work on hypersonic flow and discussed the problems of predicting pressure distributions over blunt-nosed slender bodies.

Expressions have been obtained by many authors for predicting these pressure distributions, but unfortunately the estimates do not agree with experimental measurements. It has now become generally accepted that the magnitude of viscous interaction is a function of Reynolds number based on the thickness of the leading edge; above a certain value of this Reynolds number (that is to say, if the leading edge is blunt) the pressures induced near the leading edge of a body are almost entirely due to inviscid flow effects. Afterwards, there had been much theoretical work on the details of inviscid flow fields, and some promising approximate methods have appeared—for example, the use of Newtonian flow followed by a Prandtl–Meyer expansion for flow over round noses, and the application of the intense blast-wave analogy for predicting induced pressures over the rear portion of the body.

Problems of truly blunt bodies were considered by Dr. K. W. Mangler (Royal Aircraft Establishment, Farnborough) in his paper on special aspects of hypersonic flow fields. Following the bow wave ahead of a blunt body is a region of subsonic flow, and very reasonable estimates of the flow variables in this region can be obtained from inviscid theory, provided that allowance is made for the variation of entropy across the shock, and that the equation of state is adjusted to make allowance for the different degrees of freedom excited in the molecules of the gas. Accordingly, consideration was given to a theoretical model of an inviscid flow at very large Mach number and with a ratio of enthalpy to internal energy approaching unity. Attempts to extend this work to cover the more general case of arbitrary large Mach numbers and more realistic values of the enthalpy – internal energy ratio have shown the necessity for adopting numerical techniques.

Many of these techniques deal with the inverse problem of finding the body to fit a given shock shape, which simplifies the procedure considerably, and on these lines a marching technique can be devised. The non-viscous concept gives satisfactory results for the forward-facing surface, but, behind the shoulder of the body, viscosity has to be taken into account, and it is necessary to match the values of the flow properties at the outer edge of the boundary layer with those of the flow entering from the inviscid region.

A paper on hypersonic boundary layers with special reference to aerodynamic heating by Dr. L. F. Crabtree (Royal Aircraft Establishment, Farnborough) emphasized the importance of the leading edge in problems of heat transfer. The rate of heat transfer to a bluff body, including dissociation effects, can be investigated analytically.

The dense layer of air near a highly cooled surface is relatively unaffected by pressure gradients along the surface, a concept which proved very useful in calculations of turbulent boundary layers for blunt bodies; if true local conditions are used, the intermediate enthalpy method is very useful, for undissociated flow, for both laminar and turbulent boundary layers at Mach numbers up to 10.

Dr. K. W. Mangler had mentioned the problems of lifting bodies with their associated problems of vortex and bubble type separations. From the point of view of low drag the former would appear preferable, but a planned use of the latter also has possibilities; for example, a spike protruding from the nose of a blunt body can reduce the drag. However, difficulties arise in this case, since experiments have shown high heating-rates when the flow becomes re-attached; indeed, the overall heat transfer might be higher than on the basic bluff body without a spike. Other methods have been suggested for the reduction of aerodynamic heating-rates, including ablating surfaces and transpiration cooling; for the latter method, experiment has shown that quite modest amounts of coolant blown through a wall can produce a considerable reduction in the heating-rates.

Methods of studying experimentally some of the problems of hypersonic flows were surveyed by Dr. D. W. Holder (National Physical Laboratory, Teddington). Some of the new problems can be studied with techniques which do not differ in principle from those used in research at supersonic speeds. However, to simulate fully the very high temperatures of hypersonic flight it is usually necessary to employ heaters or tunnels of unconventional design, frequently having a very short running time, or to make tests with a model launched or propelled at a very high velocity. In such tunnels the working gas is usually heated by compression, in a shock tube or by a system of shock waves, or by the discharge of electrical energy.

In addition to the usual wind-tunnel measurements of aerodynamic loading and heat transfer, the pressure, temperature and density of the working gas are required ; the degrees of dissociation and ionization and their variation with temperature and time are other properties which have to be measured within the brief period of steady flow provided by the test facility.

Types of facility at present in use include helium tunnels, arc-heated and plasma jets, hypersonic gun-tunnels, shock tubes, shock tunnels, 'hot-shot' arc-driven tunnels, free-flight wind-tunnels and free-flight rocket-propelled models ; none of these is able to simulate fully all the required conditions, but each is able to assist in investigation of the problems of some part of the hypersonic regime.

Prof. M. J. Lighthill (University of Manchester) began his paper by a detailed study of the dynamics of dissociating oxygen. Two mechanisms of dissociation exist, one by collision with another particle, the other by absorption of a photon of light. The wave-lengths of light required are in the ultra-violet range (especially 1300–1750 A.), and although at high altitudes the wave-lengths are present in sunlight, they are almost entirely absorbed by the dissociation mechanism. There is practically no light of this wave-length present at altitudes less than 60 km., and at lower altitudes all dissociation is due to collisions.

Conversely, recombination can be effected in two ways : three-body recombination and two-body combination with emission of light. The latter predominates at very low densities, say, less than 10^{-8} gm./cm.^{3}. Where aerodynamic forces are important, three-body recombination is more likely to occur.

The energy required to dissociate an oxygen molecule can be described as the kinetic energy that it would have if its speed were 5·5 km./sec. Thus, some dissociation will occur around any body travelling through oxygen at this speed. Not all molecules will be dissociated, for some of the energy will go to increase the translational, vibrational and rotational energy of the molecules.

On passing through the shock wave ahead of the body, the kinetic energy of the molecule is converted almost entirely to translational and rotational energy, and a transitional region exists before dissociational equilibrium is reached ; however, equilibrium is reached so rapidly that no direct measurements of satisfactory accuracy have been made in this region.

During dissociation the pressure increases, and this has the effect of compressing the air cap between the shock wave and the body. At very low densities the thickness of the boundary layer is comparable with that of the compressed air cap, and it has been concluded that if the surface were cooled to a temperature not much greater than that of the free stream, then the cooled boundary layer would have an effective negative displacement thickness.

A paper by Dr. J. A. Shercliff (University of Cambridge) on possible aeronautical applications of magnetogasdynamics began by stating that, in the equilibrium state, the ionization process is amenable to the same thermodynamic and statistical-mechanical treatment as the dissociation process. However, it is possible in hypersonic flow that ionization, like dissociation, can fail to reach equilibrium, and the ionization relaxation process behind a bow shock wave can occupy a region comparable in extent with the dimensions of the vehicle.

Magnetogasdynamics is generally understood to exclude the type of electron behaviour which belongs to plasma physics, and the thermodynamics of the gas is considered to be unaffected by the magnetic field.

The interaction of velocity fields with magnetic fields produces the novel features of magnetogasdynamics, and many parallels with fluid dynamics exist—for example, the so-called magnetic Reynolds number measuring the relative power of the convective and diffusive processes. If this is large, a magnetic boundary layer occurs (the skin effect, well known to electrical engineers), but in aeronautics, magnetic disturbances diffuse much more rapidly than viscous disturbances, and the viscous boundary layer can be ignored when studying the field distortion.

In aeronautics the most obvious application of magnetogasdynamics lies in its use to modify forces on, or heat transfer to, a vehicle. Drag can be produced in midstream away from the surface of a body, heat transfer to stagnation points and skin friction can be reduced by suitably orientated magnetic fields, and transition or separation of the boundary layer can be controlled. An interesting application is that in which an electrical field supplies energy through electrodes to air, accelerating it for propulsive purposes, or the converse case in which air in motion is used to generate electrical energy, which is then supplied to the vehicle to drive auxiliary systems.

The weight penalty will probably confine the use of electromagnetic rockets to interplanetary space vehicles assembled in satellite orbits. Land-based experimental facilities are not affected by the weight penalty and the possibility of high-enthalpy test plant seems attractive. Another possible use lies in the reduction of heat transfer to hypersonic nozzles.

The final paper, on aerodynamic problems of manned space vehicles, was given by Mr. T. R. F. Nonweiler (The Queen's University of Belfast). Any analysis of a project designed to carry a man into orbit and return him safely to Earth must consider the need to limit the accelerations and retardations of his passage and the temperature of his environment. There is no need to fear excessive accelerations in a powered ascent ; even with existing fuels a two-stage rocket would not necessarily involve accelerations of more than 10 g.

Descent from an orbit could be effected by the use of a glider vehicle employing aerodynamic lift ; an alternative is the so-called 'parachute re-entry' using aerodynamic drag, although whether or not a 'parachute' is employed is immaterial, for if the shape and drag of the vehicle remain constant the deceleration always has the same characteristic variation in time, reaching a maximum value of about 8*g*. Deceleration and aerodynamic heating, except in the region of the leading edge, are much reduced by employing lift in the descent, although the provision of lifting surfaces entails an increase in weight of the vehicle and the unusual stability and control characteristics pose interesting problems.

The most critical conditions will probably be encountered not in the return from a successfully accomplished orbit, but in emergency re-entry from an abortive ascent. In meeting this contingency there appears to be some advantage in the glider type of vehicle rather than the zero-lift type, but the evidence is by no means conclusive at present.

The question of a successful landing involves many possibilities. An airfield would be a remarkably elusive target in an unpowered glide which, as a result of emergency or mistake, might be initiated over the Pacific Ocean. Probably the glider would have to be regarded as expendable, the occupant being ejected by capsule at a low altitude.

B. E. BEADLE

INTERFACIAL PHENOMENA

THE biennial conference of the Physical Society, on solid state physics, was held during December 18–20 at the Cavendish Laboratory, Cambridge, under the general title of "Interfacial Phenomena". The conference was attended by about two hundred delegates and twenty-eight papers were presented, which fell into three major groups describing, respectively, various effects associated with films deposited in vacuum, the nature of solid – liquid interfaces and the formation of electrodeposited films, and the structure and properties of internal surfaces. The conference brought together physicists, physical chemists and metallurgists, each with a different approach to the study of interfacial phenomena.

In introducing the papers on films deposited in vacuum, D. W. Pashley (Tube Investments Laboratory, Hinxton Hall) gave first a brief historical survey of the experimental work on the growth of oriented deposits on substrates. He defined the terms 'epitaxy' and 'misfit' and showed that under some conditions epitaxy only occurred with a misfit of less than 15 per cent, but that in many cases misfits of much larger than 15 per cent could be tolerated. The limitations of the various techniques used for the investigation of epitaxy were then outlined, the great power of the electron microscope being emphasized.

The potentialities of the electron microscope in this field of study were fully exploited by G. A. Bassett (Tube Investments, Hinxton Hall). His experiments on nucleation, orientation and growth of vacuum-deposited metal films on ionic and metallic substrates showed that an oriented layer of gold of about 10 A. mean thickness, deposited on a single-crystal silver substrate, formed nuclei of 20–200 A. diameter which grew in size rather than number until a continuous film was formed at a mean deposit thickness of about 50 A. When gold was deposited on rock salt a similar effect was observed, but there the gold nuclei formed preferentially at slip and cleavage steps on the rock salt surface.

Reflexion electron diffraction techniques were used by R. C. Newman (Associated Electrical Industries, Aldermaston), A. Glossop and D. W. Pashley (Tube Investments, Hinxton Hall), to study the deposition of copper on silver maintained at different temperatures. They found diffraction patterns characteristic of copper with its normal lattice constant when the mean film thickness was 0·8 A. and the substrate temperature 20° C., but by increasing this temperature to 300° C. copper patterns were obtained at a mean film thickness of 0·2 A. These results showed that at above a critical mean thickness of much less than one atomic layer, aggregation of the copper occurred on the substrate surface rather than the formation of a uniform film.

Somewhat different results on the influence of imperfections in the substrate upon the mode of epitaxial growth were presented by W. J. Dunning and P. G. Fox (University of Bristol). They examined, with the optical microscope, the growth of ammonium iodide upon mica and observed a uniform epitaxial film spreading outwards until cleavage steps on the mica were reached and then a pyramidal form of growth of the iodide crystals was initiated. The importance of the substrate orientation upon kinetics of film growth was demonstrated clearly by the experiments of J. D. Lawless (University of Virginia), who had oxidized spherical single-crystals of copper in air and in copper sulphate solutions. Differences in the thickness of oxide film were shown by changes in the interference colours from different regions of the spherical surface. Examination by electron diffraction and electron microscopy showed differences in the preferred orientation of the polycrystalline oxide film on various zones of the single crystal.

The epitaxial growth of ice crystals on various substrates and its possible effect upon the formation of rain were discussed by B. J. Mason (Imperial College of Science and Technology, London). He described observations on the nucleation of ice on covellite which showed that after nucleation ice crystals may spread laterally on the surface without thickening. The experimental technique involved observing, with the optical microscope, the interference colours produced by the thin crystals on the cleaved covellite surface, and Dr. Mason illustrated his results with colour micrographs of kaleidoscopic variety.

Two further papers on electron diffraction studies of epitaxial growth were presented by M. Blackman (Imperial College of Science and Technology, London), who discussed the epitaxial polymorphism of thallium and cæsium halides, and H. Wilman (Imperial College), who gave some new examples of epitaxy. He showed many diffraction photographs illustrating the different forms of epitaxial growth on ionic, organic and metallic substrates of deposits condensed *in vacuo* or formed by chemical action.

A group of papers on the properties of surface films were presented next. J. A. Bennet (British Scientific Instrument Research Association) described an apparatus which enabled him to measure the electrical resistivity of a gold film as it was being deposited on either alumina or on a substrate of bismuth oxide on alumina. He found the resistivity decreased as the thickness of the film increased, an effect which he attributed to changes in continuity of the film. This conclusion was in agreement with the results given by previous speakers, who showed that in the earliest stages of deposition an epitaxial film was not continuous.

The adhesion of evaporated metal films to glass was discussed by C. Weaver and P. Benjamin (Royal Technical College, Glasgow). The load required to leave a clear scratch through a metal coating deposited in vacuum on a glass substrate was measured and found to depend upon the time which had elapsed after deposition in the case of iron and aluminium, but not for gold. The adhesion of the gold could be attributed to Van der Waals forces, but the rapid increase in the adhesion and its greater value in the case of iron and aluminium could only be accounted for if some chemical bonding occurred between the glass and evaporated layer. Further experiments which tended to confirm that oxygen was necessary to produce this bonding were then described. An entirely different approach to the problems associated with deformation of evaporated layers on substrates was adopted by T. Evans (Tube Investments, Hinxton Hall). An oriented film of gold about 300 A. thick was evaporated on to a single crystal of silver, and on top of the gold film a polycrystalline film of carbon, platinum, iron or chromium was deposited. The composite specimen was then deformed. By dissolving away the silver a specimen thin enough to be examined directly by transmission in the electron microscope remained. This revealed that the presence of the polycrystalline layer modified the slip distribution in the substrate. Dr. Evans concluded that some of the effects could be attributed to adhesion between the polycrystalline and the gold layers.

The first section of the conference was completed by two papers on the surface tension of metallic interfaces. H. Mykura (University of Glasgow) showed that the shape of the grooves produced at grain boundaries when a metal surface is etched thermally depended upon the difference of orientation between the grains, while J. M. Blakely and H. Mykura (University of Glasgow) calculated how an exposed metal surface having a sinusoidal form would change its shape on heating by a process of self-diffusion leading to mass transport against curvature gradients.

Five papers were presented describing phenomena associated with solid – liquid interfaces. Prof. F. C. Frank (University of Bristol) discussed the kinematics of deposition and dissolution profiles of crystals and showed how the theory of kinematic waves was applicable to this study, while a review of phenomena at metal – electrolyte interfaces was given by R Parsons (University of Bristol), who summarized current ideas about the structure of the electrical double layer between a metal and an electrolyte.

The work of the J. Lucas research group on electrodeposition was introduced by M. J. Pick (University of Birmingham). After reviewing earlier work on electrodeposition he described their new investigations on the deposition of copper on single crystals and polycrystalline cube-texture copper. As in the case of vacuum deposition, the electro-deposited metal initially formed nuclei which eventually grew into each other, forming well-defined crystals. The shape of the nuclei was found to vary with the orientation of the substrate. Further aspects of the work of this research group were then presented by G. C. Storey, T. B. Vaughan and V. R. Howes (University of Birmingham). Changes in surface topography with changes in cathode orientation were determined by detailed light and electron optical examination, and the results obtained were explained in terms of bunching of the growth layers in the manner described in the earlier paper by Prof. Frank. A ciné film of deposits growing in a cell on the stage of an optical microscope were shown ; in one sequence growth by a spiral mechanism was clearly recorded.

Further experiments on the growth of electrodeposits of face-centred and body-centred cubic metals on single crystals of face-centred cubic substrates were described by H. Wilman and A. R. N. Reddy (Imperial College of Science and Technology, London). Examination of the deposits by electron diffraction showed that initially epitaxial growth occurred, but that in some cases this was accompanied by rotational disorientation.

The smoothing of electrode surfaces by anodic dissolution or cathodic deposition was discussed by J. Edwards (British Non-Ferrous Metals Research Association), who showed how the potential distribution, hence the rate of solution or deposition, was influenced by the topography of the electrode surface.

The papers on internal surfaces were introduced by J. Nutting (University of Cambridge). He outlined first the forms of internal surfaces thought to exist in pure metals, single-phase and two-phase alloys, and then discussed in more detail the structure of interphase interfaces. New results, obtained by transmission electron microscopy of thin metal foils, on the coherent interfaces found in aluminium alloys after suitable aging treatments were described, and the transition from coherent to partially coherent interfaces was shown to occur by the introduction of suitable structural dislocations.

The properties of grain boundaries are frequently discussed, but not often measured. An attempt to obtain quantitative information was described by G. M. Leak (British Iron and Steel Research Association, Sheffield), who showed how the dependence of temperature of the internal friction of iron could be related to its grain size. The relaxation time of the grain boundary damping was also found to be dependent upon alloy content, different results being obtained with interstitial and substitutional elements. P. B. Hirsch and M. J. Whelan (University of Cambridge) and R. Bullough (Associated Electrical Industries, Aldermaston) were more concerned with low-energy interfaces associated with deformation twins. Drs. Hirsch and Whelan described a mechanism for the formation of deformation twins and then discussed this in relation to the contrast effects obtained when examining thin metal foils of stainless steel in the electron microscope, while Dr. Bullough presented a theoretical treatment of the properties of structural dislocations and their movement during the extension of a twin interface.

A series of papers on the influence of interphase interfaces upon the mechanical properties of alloys were then presented. Experiments on the plastic deformation of aged aluminium–copper and aluminium–silver alloys were described by A. Kelly (University of Cambridge), who showed that after aging an aluminium–copper alloy to produce *G.P.* [1] zones the critical resolved shear stress at a given elongation was very sensitive to temperature, whereas after aging to produce *G.P.* [2] zones, or the spherical zones in aluminium–silver alloys, there was no thermally activated component. He deduced from these results that, with the aid of thermal fluctuations, dislocations could be made to pass through the narrow

G.P. [1] zones, but with the larger and thicker *G.P.* [2] zones thermal activation could never provide sufficient energy for the disruption of the zones. The mechanism of hardening in aluminium–copper alloys was discussed further by D. Dew-Hughes and W. D. Robertson (Yale University). They carried out tensile tests on single crystals of alloys which contained between 1 and 5 per cent copper and which had been aged at different temperatures and then used the results obtained to test the predictions of Orowan, Fisher Hart and Pry on the relationships between the shear stress and the particle spacing. The conclusion was reached that a modification of the Fisher Hart and Pry relationship gave agreement between the observed and calculated results. To account fully for the effects of aging upon the critical resolved shear stress, Dew-Hughes and Robertson derived the stresses required to force dislocations through the solid solution, then to pull them through the coherent strain fields surrounding the zones and finally to disrupt the zones. The sum of these three component stresses agreed closely with the observed shear stresses.

The conclusions of Kelly and of Dew-Hughes and Robertson on the modes of dislocation precipitate interactions were supported by the results presented by G. Thomas and R. B. Nicholson (University of Cambridge). They examined in the electron microscope thin foils of suitably aged aluminium alloys and observed how the dislocations interacted with coherent, partially coherent and incoherent precipitates. Clear evidence for the passage of dislocations through coherent and partially coherent precipitates was presented. But there was little evidence for the dislocation loops forming around precipitate particles as predicted by Fisher Hart and Pry. Further results on precipitate – dislocation interaction were given by E. Smith (Associated Electrical Industries, Aldermaston), who described the effects of hydride precipitates upon the plastic deformation of titanium and showed how the reversible twinning found in pure titanium was hindered by the hydride precipitates. Under conditions of rapid loading cracks developed from the interface between the hydride and the hindered twin.

The generation of dislocations at incoherent interfaces was discussed by J. W. Mitchell and A. S. Parasnis (University of Bristol). They showed how, in a dispersion of glass spheres in silver chloride, the stresses developed at interfaces due to differences in thermal contraction of the two phases could lead to the formation of dislocations by a process of prismatic punching. Optical micrographs were shown of the dislocation loops and their spatial distribution within the silver chloride matrix. Another function of interfaces, as a source of vacancies, was demonstrated by R. S. Barnes (Atomic Energy Research Establishment, Harwell) and Prof. A. H. Cottrell (University of Cambridge), who had investigated the effects associated with the annealing of radiation damage in copper produced by bombardment with α-particles. They found small bubbles were produced on annealing and reasoned that these were formed by the diffusion and aggregation of vacancies from either the nearest free surface or internal surfaces such as large-angle grain boundaries; convincing proof that twin interfaces did not act as sources for vacancies was produced. The influence of curvature on the energy of incoherent interfaces was illustrated by a film presented by G. Thomas and M. J. Whelan (University of Cambridge). Thin foils of an aluminium – 4 per cent copper alloy were aged at temperatures between 350° and 450° C. on a heating stage in the electron microscope while the structural changes as observed on the fluorescent screen of the microscope were recorded with a ciné camera. The nucleation and growth of the θ phase was clearly revealed together with the subsequent growth of the larger particles at the expense of the smaller ones.

From the conference it appeared that at the present stage of development the physicists and metallurgists had more to offer than the physical chemists towards our understanding of interfacial phenomena. The advances made since the introduction of electron diffraction techniques for the study of surfaces have been very great, but with the advent of the electron microscope into this field of study a much more detailed investigation of surface morphology has become possible. The explanation of why diffraction patterns could be obtained from deposits of less than one atom mean thickness has now been found, but it is still difficult to account for the preferential formation of epitaxial nuclei at lattice defects. Perhaps it is here that the physical chemists can be of help.

J. Nutting

THE COLOMBO PLAN

ANNUAL REPORT

THE seventh annual report of the Consultative Committee for the Colombo Plan for Co-operative Economic Development in South and South-East Asia, which by agreement at the Singapore meeting of the Committee in October 1955 has been extended from July 1957 to June 30, 1961, is the last to appear before the future of the Plan is again considered at its 1959 meeting in Indonesia. The present report*, which covers the year 1957–58, records continuing increase in industrial production in the area as a whole, but in India the rate of expansion dropped from 8 per cent in 1956–57 to 1·5 per cent, which, however, accounted for most of the 13 per cent increase in output of electric power. Since 1950 training has been given to more than 15,500 trainees from countries in the area, and the services of nearly 8,000 experts provided by members of the Colombo Plan and by agencies of the United Nations. During 1957 expenditure on technical assistance under the Colombo Plan Technical Co-operation Scheme increased to about £3 million, reaching a total of £9·78 million since 1950, and during the first six months of 1958 it reached 3·9 million dollars.

Almost half of this expenditure has been for the provision of study and training courses, about a quarter for the supply of experts and the remainder on technical equipment. By the end of June 1958 expenditure on technical equipment reached a total of £2·35 million, and the number of scholarships and training awards granted by member countries totalled 6,952, an increase of 1,330 on the previous year.

---

* The Colombo Plan for Co-operative Economic Development in South and South-East Asia—Seventh Annual Report of the Consultative Committee, Seattle, Washington, November 1958. Pp. 192. (Cmnd. 610.) (London: H.M. Stationery Office, 1958.) 8*s*. net.

There were then 2,091 trainees taking courses in member countries. During the year there were 221 technical experts in the field compared with 207 in the previous year, making a total of 1,002 since the Plan began. The number of experts supplied in medical and health fields dropped sharply, but the number of engineering experts increased, and the number of those in food, agriculture and forestry and in transport and communications continued to increase.

Outside the Technical Co-operation Scheme, the United States, which has already provided, since the inception of the Plan, almost 4,000 million dollars in economic and technical assistance to Colombo Plan countries, continued to provide large-scale technical assistance. About 1,500 trainees were received in the United States and 543 trainees undertook instructional courses with United States assistance in the Colombo Plan area, while on July 1, 1958, about 2,000 United States technicians were on duty in Colombo Plan countries. Under the Mutual Security Programme and the President's Fund for Asian Economic Development, 408 million dollars were made available to Colombo Plan countries during the year, and finance was provided for a Radioisotope Centre in Burma, including arrangements to train Burmese in nuclear techniques in the United States. Laboratory equipment was provided for a course in nuclear physics at the University of the Philippines, and scientists from the Philippines and Thailand are being trained in the United States.

During the year, fewer new Colombo Plan scholarships and training awards were granted, partly because of the pressure on existing training institutions but partly also because of the marked increase in the number of long-term awards. The establishment and development of training facilities within the area accelerated and 20 per cent of the training awards under the Technical Co-operation Scheme are now provided within the area. Looking to the future, the report again stresses the need to ensure that technical and managerial skills are developed at a rate sufficient to permit the effective use of capital and other available resources. The technical ability of the population must keep pace with the expansion of development and it is now urged that the less-developed countries give greater attention to the development of human skills required for the effective and appropriate utilization of resources. Finally, stress is laid both on the value of co-operation and of the more rapid development of technical training facilities within the area.

BEAR ISLAND COD

DURING the summer, shoals of cod, consisting mainly of immature individuals, move into feeding grounds off Bear Island near Spitsbergen. These concentrations form an important fishery resource, and for the past ten years, part of the work of the Fisheries Laboratory, Lowestoft, has been to trace the migrations that lead to this shoaling behaviour.

In doing this work*, Mr. G. C. Trout has been greatly helped by discovering that these cod have two main kinds of otoliths, which he calls split-zone and opaque-zone types. Both kinds are found in roughly equal proportions on the more southerly grounds, but with increasing distance from Bear Island the two tend to become segregated. This and other evidence suggested that the shoals advancing on Bear Island separate into two groups, one moving north-eastwards in the direction of Hope Island and the other northwards to Spitsbergen. Tagging experiments carried out during 1951 and 1952 were in keeping with this hypothesis and showed that in late autumn the fish returned to winter quarters in the Bear Island area.

Trout suggests that these facts and others are consistent with the general idea that the annual migratory cycle of the Barents Sea cod populations is closely linked with the movements of the water masses. During their summer migrations the feeding cod are partly pelagic in habit (due to daily vertical migrations in response to light conditions) and may thus drift northwards in the West Spitsbergen current or in a branch of the North Atlantic drift. The return migration in winter is against the current and takes place along the bottom in the absence of light (and the lack of daily vertical movement in the fish). The distribution of the cod is thus seen to be ". . . the resultant of interaction of changing behaviour with the cycle of movement of the water masses in which the cod are found".

This would seem to be a useful working hypothesis. Perhaps it will prove to be partly right, but the fact that it can be posed at all is a measure of the work being undertaken by the Fisheries Laboratory at Lowestoft.

PROGRESS IN BRITISH FORESTRY

THE thirty-eighth annual report of the Forestry Commissioners for the year ending September 30, 1957*, reviews both the record of work accomplished in Britain and the national situation in relation to policy and programmes adopted by the Government. The record as a whole must be accepted as quite satisfactory, with encouraging features indicating that some at least of long-standing difficulties are being overcome, even if others, such as that of acquiring land for afforestation, have definitely held up progress in planting work. Criticism has been made in the past that not enough was being done to get the productivity of the privately owned woodlands—still the greater proportion over the country as a whole and still far from having recovered from the onslaught of two world wars—restored and brought up to the levels possible with skilled management. The rate of planting by private owners has nearly doubled in the past five years and has increased by as much as 4,500 acres in 1956–57, compensating for a drop of the same order in the State's own total. This increase is significant as revealing a changed situation which has been widely discussed, both in

Parliament and among foresters, and one to which the Zuckerman Report also directed attention.

The national policy since the end of the First World War has been to build up a stock of standing timber estimated to be adequate to make Great Britain independent of imports of wood over an emergency lasting about five years, and the question is naturally being asked whether, with the changed conditions now prevailing, we should still continue to retain the same target of 5 million acres of productive forest. Although it can be demonstrated that there is still enough suitable land, there are practical difficulties in acquiring it, and, of course, afforestation implies a large capital investment at a time when there are innumerable demands for capital. Forestry is unquestionably becoming more attractive to the private investor despite the current drop in prices, while the Government is also tending to place the emphasis on the economic and social benefits of forestry rather than on the earlier strategic reasons.

An important factor is certainly that more and more of the new forests in Britain are coming into production, often large-scale production, and it is obvious that the annual output is going to rise steadily for as many years to come as we have maintained a large planting programme. Not only is this giving more and more local employment, but also one centre after another is seeing new industrial units open up, or existing ones expanding: in the year under report, this has happened in Flintshire, Lancashire, Dumfriesshire and Monmouthshire, and this is clearly only a beginning. It is noteworthy, too, that 400 miles of new roads have been completed, with 313 more under construction, reducing the inaccessibility to modern amenities that has hitherto contributed so much to rural depopulation. The only other feature of this report which can be referred to here is the attention given to developing the social aspects of forestry, particularly in connexion with the national forestry parks, which all record very significant increases in the numbers of visitors and for which an excellent series of small guides has been issued. The special importance of awakening an interest in forestry among the rising generation is receiving recognition in the form of the provision of facilities in the forests for schools and for colleges for the training of teachers.

H. G. CHAMPION

FORMATION OF ABERRANT CELL WALLS AND OF SPORES BY THE GROWING YEAST PROTOPLAST

By A. A. EDDY* and D. H. WILLIAMSON
Brewing Industry Research Foundation, Nutfield, Surrey

THE so-called protoplasts which have been isolated by exposing various micro-organisms to conditions favouring dissolution of the cell wall may be placed in two main categories depending on their ability or inability to reform a normal cell wall on cultivation and thereby to revert directly to cells of the parent type[1]. Work in these laboratories with protoplast-like bodies released from yeast by the action of gut-juice from *Helix pomatia*[2] has now brought to light the interesting situation that, whereas they have never been observed directly to revert to whole cells, they nevertheless are capable of giving rise to a superficial membrane which, to some extent, resembles the normal wall of the yeast cell. However,

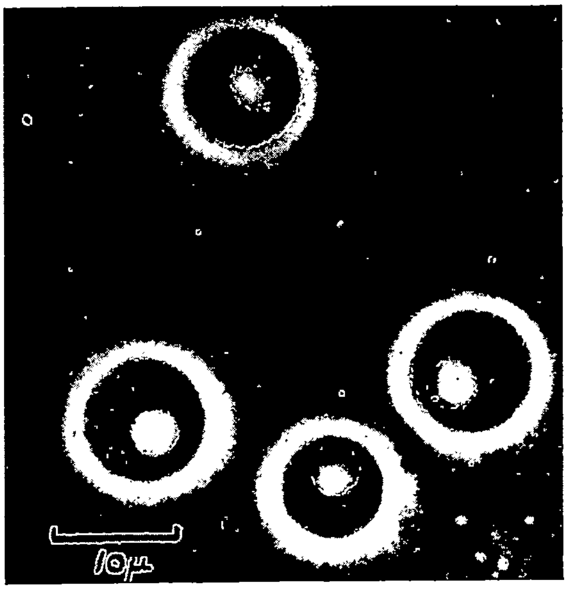

Fig. 1. Freshly isolated protoplasts

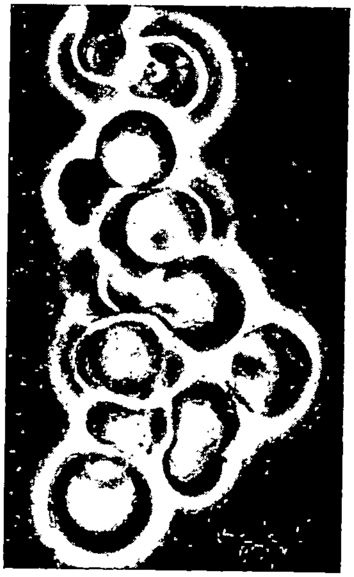

Fig. 2. Protoplasts suspended for 2 hr. at 25° C. in malt extract medium (ref. 3) containing 10 per cent (w/v) glucose

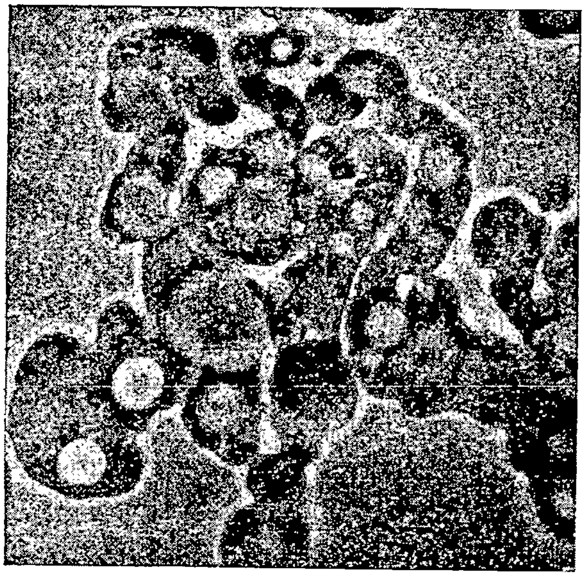

Fig. 3. Protoplasts after incubation for 40 hr. at 25° C. on solid malt extract medium (ref. 3) containing 10 per cent (w/v) mannitol

conditions have been found which induce the protoplasts to form spores from which whole cells may arise on germination, the process thus providing an indirect means of effecting reversion to the normal state.

The method of isolating protoplasts was modified from that previously described[2]: (1) by using mannitol as an osmotic stabilizer instead of rhamnose; (2) by effecting solution of the wall at 30° C. rather than at 25° C.; (3) by using 5 mgm./ml. instead of 1 mgm./ml. of snail enzyme. Under these conditions, more than 90 per cent of the cells of *Saccharomyces carlsbergensis* (National Collection of Yeast Cultures, strain 74) were converted into protoplasts in 2–3 hr., the product containing not more than 0·1 per cent viable whole cells as determined by plating it on a solid medium lacking mannitol.

Samples of protoplasts (10^7–10^8/ml., final concentration) were transferred to a series of nutrient media which were either based on malt extract[3] or were of the synthetic type[4]. The media were supplemented with either mannitol, glucose, maltose or sucrose at selected concentrations equivalent to osmotic pressures of 10–20 atm. When malt-extract was used, aureomycin (20 μgm./ml.) was included to suppress growth of bacteria. Examination of samples withdrawn at intervals from cultures variously held at 18–30° C. for periods of up to 2 weeks revealed that the protoplasts underwent a sequence of striking changes in appearance. For example, 1–2 hr. after transfer to a complete growth medium, the surfaces of the protoplasts displayed irregular local swellings (Figs. 1 and 2) which, during a subsequent 30 hr., tended to develop into massive irregularly shaped outgrowths (Fig. 3), the protoplasts themselves increasing 5–50 fold in volume. That a form of growth was involved in these changes was readily demonstrated by showing that the respective contents of protein, ribonucleic acid and insoluble anthrone-positive carbohydrate, determined by conventional methods, increased several-fold during the first few hours.

The way in which swelling of the growing protoplasts occurred suggested the presence of a fairly rigid membrane defining the outline of the cell at each stage of growth. In fact, such membranes

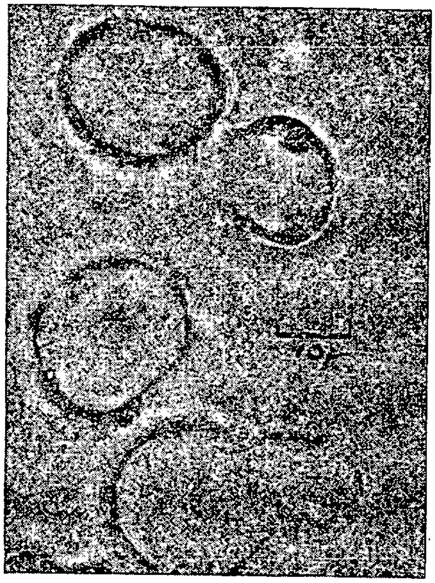

Fig. 4a. Aberrant cell walls (phase contrast)

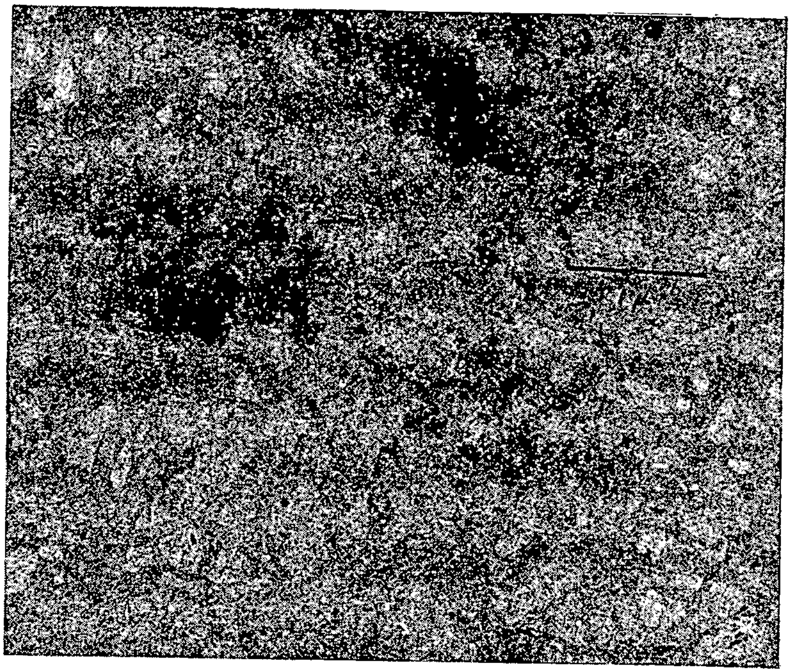

Fig. 4b. Aberrant cell walls (unshadowed electron micrograph)

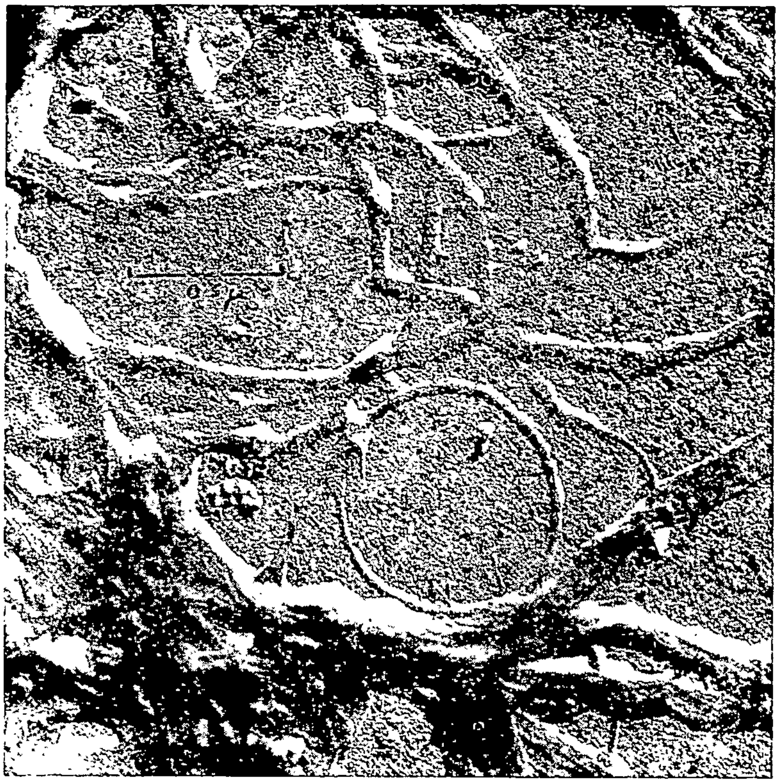

Fig. 4c. Aberrant cell walls (shadowed electron micrograph)

were present and could readily be detected on adding an excess of water (10 vol.), which caused the contents of the protoplasts to disperse while the outer envelopes were preserved. No trace of the membranes was found, however, when freshly isolated protoplasts were lysed in this way.

In order to examine them further, the membranes released by lysis were centrifuged at 1,000*g* for 5 min. and washed with water. They were then shaken for 10 min. with fine glass beads in a Mickle disintegrator in order to remove adhering debris, and recovered once more by centrifugation. The form and fine structure of the membranes are illustrated in Fig. 4*a*, *b* and *c* (electron micrographs obtained by courtesy of Metropolitan Vickers, Ltd.), respectively, while their composition is contrasted in Table 1 with that of normal walls derived from the same strain of yeast.

A striking feature of the composition of the material comprising the aberrant walls is its relative deficiency in amino-acid residues, most of the nitrogen content, in fact, being accounted for as N-acetylglucosamine. This circumstance may be attributed to the absence from the surface of the protoplast of a specific protein template which, in the case of the intact cell, plays a direct part in the synthesis of new cell wall material. In these terms, the aberrant walls can perhaps be regarded as representing part of the basic structure of the normal wall.

The results obtained on culturing the protoplasts in synthetic medium deficient in available nitrogen were quite different from those described above in that little or no irregular

Table 1. COMPARISON OF CELL WALLS PRODUCED BY THE PROTOPLAST WITH THOSE FROM THE PARENT YEAST

	Nitrogen (per cent dry wt.)	Phosphorus (per cent dry wt.)	N-acetyl glucosamine* (per cent dry wt.)	Invertase† (μmole sucrose/mgm. wall/hr.)
Normal cell wall	1·0	0·19	0·9	6
Protoplast wall**	2·2–2·7	0·03	27–33	≮ 0·03
	Amino-acids	**Mannose‡**	**Glucose‡**	**Anthrone-positive§ carbohydrate (per cent dry wt.)**
Normal cell wall	+++	+	++	55
Protoplast wall**	±	+	++	35–45

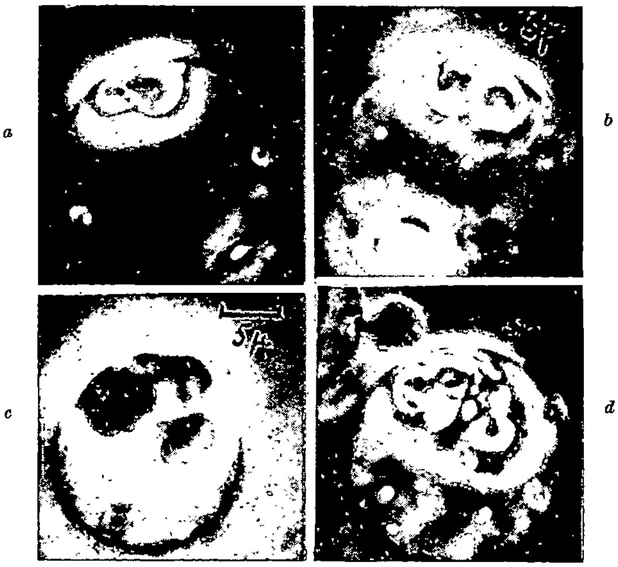
* Determined after hydrolysis for 72 hr. with two successive portions of snail enzyme (ref. 7).

† Measured at 25° C. in presence of 0·01 *M* acetate buffer, *p*H 5·3. Activity of normal walls was shown to be twenty times greater than could be accounted for by the proportion of whole cells present.

‡ Found after hydrolysis with sulphuric acid (70 per cent v/v) for 2 hr. (ref. 7).

§ Calculated as glucose equivalent.

** Values refer to three independent preparations.



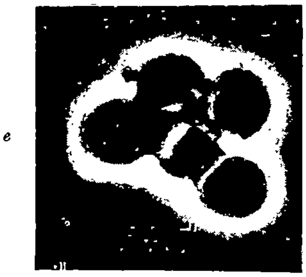


Fig. 5*a–d*. Spores forming within protoplasts held for 40 hr. at 25° C. in a synthetic medium (ref. 4) from which ammonium sulphate was omitted, supplemented with 0·1 per cent (w/v) glucose and 10 per cent (w/v) mannitol at *p*H 6·5. *e*, a cluster of spores released by diluting such a culture

swelling of the protoplasts occurred. They tended instead to develop a large main vacuole at the perimeter of which, and still within the protoplast itself, a cluster of 2–5 highly refractile spherical bodies each of about 3μ diameter could be discerned (Fig. 5). The appearance of these refractile bodies, their ability to develop into mixtures of haploid and diploid cells on being transferred to nutrient media of low osmotic pressure, as well as their reaction to the spore stain of Bouthilet[5], strongly suggested that they were, in fact, spores in various stages of development. In this connexion, it may be significant that culture of the parent yeast itself in a similar nitrogen-deficient medium also resulted in a good yield of ascospores being obtained.

It is stressed that throughout this work no evidence was obtained that the yeast protoplasts were able to produce intact cells other than through spores as an intermediate stage. This conclusion is apparently at variance with the work of Nečas[6], who claimed to have observed direct development of yeast cells from protoplast-like bodies originally obtained from a spontaneously lysing yeast. While this author seems to have encountered material such as that illustrated in Fig. 3, he apparently failed to detect development of aberrant cell walls. It is interesting to speculate that, under the conditions employed by Nečas, spores may have been formed and have germinated so rapidly that their presence was not detected. In this connexion it may be significant that Nečas found regenerated yeast cells to differ both among themselves and from the parent strain, an observation which would be compatible with their having *originated* from different spore segregants.

CÆSIUM-137 IN SWEDISH MILK AND SOIL

By K. LÖW and K. EDVARSON
Research Institute of National Defence, 2nd Division, Stockholm 80

THE cæsium-137 content of dried milk from mid-Sweden and in soils from different locations has been determined by γ-spectrometric methods. One dried milk sample was from 1947, the others from 1955–58 (kindly provided by Svenska Mjölkprodukter AB, Stockholm). The soils were sampled in the summer of 1957. Three samples, consisting of the layers 0–2·5, 2·5–5 and 5–10 cm. were taken at each place.

Cæsium-137 was determined directly by γ-spectrometry without chemical separation. The detector was a 4 in. × 4 in. sodium iodide (thallium) crystal, made by Harshaw Chemical Co., with copper housing and 'Pyrex' window. To get a high geometrical efficiency the sample container made of thin copper sheet was so shaped that the sample formed a layer of uniform thickness around the crystal (cf. Fig. 1). The volume of the container was 0·7 l., corresponding to about 500 gm. dried milk and 600–1,000 gm. soil. The detector unit was surrounded by a 10-cm. lead shield. The pulse analyser was of the Hutchinson-Scarrot type with 70 channels and was used with a channel-width of 25 keV.

					Mean	6·0	8·5

* W, whole milk; S, skimmed milk. The estimated errors are: col. 3, ± 1; col. 5, ± 0·1.

The only detectable γ-activity in the milk was due to cæsium-137 and potassium-40. A typical γ-spectrum of dried milk is shown in Fig. 2. The absolute efficiencies and the shape of the spectra of these activities were determined by measuring milk samples with known amounts of cæsium-137 and potassium added. The lower curve in Fig. 2 was obtained by subtracting the potassium contribution, determined from the 1·45-MeV. photopeak. The shape of this curve fits well with the cæsium-137 spectrum determined in the calibration. A counting time of 2 hr. gives a statistical error of 5–10 per cent in the determination of cæsium at the present levels of milk activity (~ 20 pc./gm. potassium).

In the soils, the cæsium-137 activity could not be determined directly because of the radium and thorium content. In particular, the 0·61-MeV. line due to radium C, which is of high intensity and is close to the 0·66-MeV. line due to cæsium-137, interferes.

There is reason for believing that the cæsium-137 content in the 5–10 cm. layer is much lower than that in the upper layers, whereas the composition of the natural activity (thorium, radium, potassium) might be about the same for the three layers. Thus it would be possible to determine cæsium-137 from the difference in γ-spectra between a top layer and the bottom layer. In Fig. 3 the γ-spectra from the 0–2·5-cm. and 5–10 cm. layers of one soil are given. Above 0·8 MeV. the shapes of the spectra are the same within the statistical errors, indicating that the relative amounts of the components of the natural activity are the same. By normalizing the spectrum of the bottom layer to give the same intensity above 0·8 MeV. as the upper layer and subtracting it from the latter, a residue was obtained mainly consisting of a well-resolved cæsium-137 peak. Clearly, the amount of cæsium-137 in the bottom layer must be very small compared with the upper layer if this method is to give the true content of cæsium-137. The known behaviour of cæsium tracer in soils[1] indicates that this assumption is justified. The same calibration as for dried milk was used, because the difference in density and composition between soil and dried milk is estimated to be of small importance with the present geometry. With a counting time of 1 hr. the error in the cæsium-137 determination is estimated to be ± 40 pc./kgm. soil at the present low levels of activity.

Table 2. SOIL TYPES AND PRECIPITATION-RATES

No.	Location	Type of soil	Yearly precipitation-rate (mm.) Mean 1955–57
1	Skarhult 55·9° N., 13·3° E.	Moraine loam	570
2	Fröslida 56·8° N., 13·0° E.	Fine sand	1,180
3	Ultuna 59·8° N., 17·7° E.	Heavy clay	530
4	Offer 63·0° N., 18·0° E.	Silty clay loam	500

Measurements on soils sampled during the summer of 1958 were started in August 1958. In this case the main γ-activity in the top layer is due to zirconium + niobium-95 (0·75 MeV.) in fall-out during the first half of 1958. It is estimated that a determination of cæsium-137 for these soils will be possible in 1959, when the zirconium + niobium-95 has decayed sufficiently.

(*a*) *Milk.* The results are given in Table 1. For comparison the content of strontium-90, determined radiochemically by S. Häggroth[2], is also given. As is to be expected, the sample from 1947 contains no detectable cæsium-137 or strontium-90 activity. It is not possible with the present material to find any trend as regards the variation with time in the other values. The correlation between cæsium-137 and strontium-90 is, however, quite good. Assuming a linear dependence, the coefficients of correlation are 0·84 and 0·91 for columns 2–5 and 4–6 respectively.

(*b*) *Soil.* Some characteristics of the soils are given in Table 2 and the results are summarized in Table 3. The amounts of activity seem to be in reasonable agreement with measurements of activity

in precipitation[3]. A detailed comparison is not possible until more extensive material is available. The ratio cæsium/strontium is in fair agreement with measurements made by N. G. Stewart *et al.*[4].

The results indicate that there is a good correlation between the cæsium-137 and strontium-90 values not only in soils, where it is to be expected, but also in milk. It is of course quite probable that regions with different climatic and agricultural conditions will give milk with different ratios of cæsium-137 to strontium-90, but within each region it seems possible to use the cæsium-137 values for an estimation of the strontium-90 content, provided that the contamination is due to atomic bomb debris. As the determination of cæsium-137 is far more rapid than the radiochemical determination of strontium-90, this would have practical advantages.

As regards the soils, the direct determination of cæsium is of special value, as the present radiochemical methods for the determination of strontium-90 mostly involve an extraction of the soil, the efficiency of which it is extremely difficult to determine.

HAIR RECEPTORS IN LOCUSTS

Hair Plates on the First Cervical Sclerites of the Orthoptera

MITTELSTAEDT[1] has described four pairs of hair plates in the neck of the dragonfly, *Anax imperator*, which register movement of the head relative to the body. A pair of hair plates found in the neck of the locusts *Schistocerca gregaria* and *Locusta migratoria migratorioides* (Fig. 1) has been shown to fulfil a similar function. The tip of the first cervical sclerite on each side of the neck bears an oval swelling covered with fine hairs (Fig. 2) at the point where it forms a ball-and-socket joint with the post-occipital condyle of the head. Several types of head movement, in particular rotation of the head relative to the long axis of the body, deflect these hairs and also some, at least, of the hairs on the anterior edge of the prothorax. The hair plate is innervated by a branch of the second pair of nerves from the first thoracic ganglion; a second branch of this nerve runs up to the anterior edge of the prothorax.

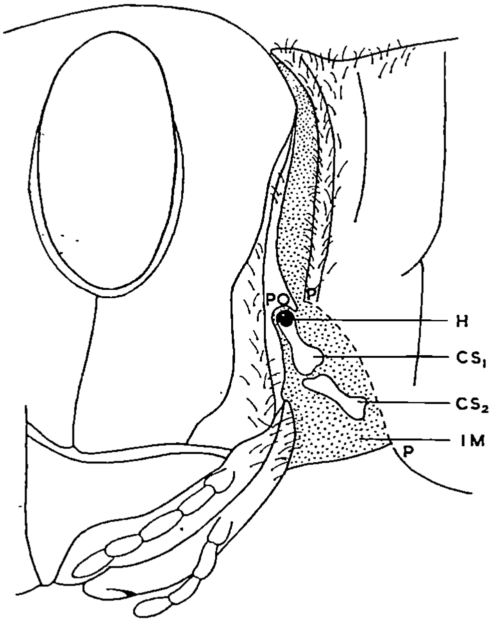

Fig. 1. Diagram of part of the head and prothorax of *Schistocerca gregaria* with the head pulled slightly to one side to reveal the intersegmental membrane, cervical sclerites and hair plate. Some of the hairs present on the prothorax and head are also shown. *P–P*, pronotum cut away to reveal the cervical sclerites; CS_1, CS_2, first and second cervical sclerites; the second sclerite articulates with the region of the pronotum that has been removed; *H*, hair plate; *PO*, post-occipital region of the head; *IM*, intersegmental membrane

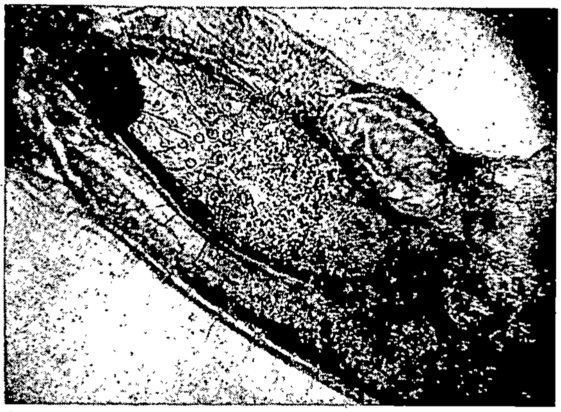

Fig. 2. A photograph of the tip of the first cervical sclerite, showing the oval swelling of the hair plate bearing many fine hairs

Laboratory studies with flying locusts have demonstrated that *Schistocerca* and *Locusta* show a dorsal light reaction, similar to that shown by *Anax*, turning about the longitudinal axis until the greatest light-intensity falls on the dorsal ommatidia, then continuing to fly in this position. The head is turned until the dorsal ommatidia are perpendicular to the light source and the body is then rotated to be aligned with the head. The ability of the locust to remain thus orientated is reduced if all the hairs on the anterior edge of the prothorax are destroyed, and it is extremely difficult for it to do so if the hair plates are destroyed. If both the hair plates and the prothoracic hairs are destroyed the locust still rotates until the dorsal ommatidia are perpendicular to the light source but is completely unable to remain orientated in this position because the body cannot be maintained in the correct angular position relative to the head. The hair plates, and to a lesser extent some of the prothoracic hairs, function as proprioceptors registering relative head and body movement.

Hair plates have been found on the first cervical sclerites of representatives of all the main families of Saltatoria. They are present in flightless subterranean species such as *Gryllotalpa gryllotalpa* and *Cylindracheta* sp., in brachypterous species like

Pholidoptera griseoaptera, and in wingless forms such as *Lentula callani*, as well as in alate species such as *Chorthippus brunneus*. They are well developed in nymphs as well as adults and it seems likely that they have a similar proprioceptive function throughout the order.

This work was carried out during the tenure of a Senior Research Award from the Anti-Locust Research Centre, London.

Function of certain Prothoracic Hair Receptors in the Desert Locust

The behavioural experiments of Goodman (previous communication) suggest that registration of displacement of the head relative to the body—particularly rotational movement—in *Schistocerca gregaria* is carried out at least in part by external proprioceptors, consisting of hair sensillæ on the cervical hair plates and on the anterior edge of the pronotum. This view would be corroborated if the responses of the hairs were found to be those typical of other insect hair proprioceptors, such as those described by Pumphrey[1] and Pringle[2].

Attempts were therefore made to record the electrical discharges in the nerves supplying these hair receptors while the latter were stimulated with a mechanically controlled glass needle. The hairs are innervated by branches of the second nerve of the first thoracic ganglion; using fine platinum wire electrodes and a high-impedance input d.c. amplifier, it proved impossible to record discharges in the nerves supplying the cervical hair plates, which were so fine that the necessary dissection either broke them or caused them to dry out rapidly. It was possible, however, to record discharges in the nerve supplying the hair sensillæ distributed along the anterior edge of the pronotum. A constant maintained deflexion of a single hair with a fine glass needle then produced a relatively high initial discharge frequency (200–300 impulses/sec.) which became adapted rather rapidly to a steady level of 40–50 impulses/sec., which was maintained for a long period (Fig. 1). The response was obtained to deflexion of the hairs in any direction and the initial frequency of discharge appeared to depend both on the speed and magnitude of the original deflexion; the adapted frequency, however, bore no relation to the magnitude of the deflexion, as Pumphrey[1] found in certain cockroach proprioceptors, and indeed this level was very similar in all preparations (Fig. 1). The hairs could be stimulated by gross air movements and also by pure tones in the range 100–500 c./s., if these were of sufficient intensity; in the latter case the response was synchronous with the stimulus frequency.

The responses described above are very similar to those found by Pumphrey[1] and Pringle[2] in certain insect hair sensillæ now agreed to be proprioceptors, and certainly fit the receptors for the role suggested for them by Goodman. The pronotal receptors on one side, up to the dorsal median line, are innervated by the nerve of that side; thus, with the two cervical hair plates, there are in all four hair beds, disposed in such a way that information about the equilibrium position and direction of rotation of the head relative to the body can be registered. It seems likely that the cervical plates register the equilibrium position, while the prothoracic hairs register movement; this speculation is supported by Goodman's evidence that removal of the cervical plates makes the maintenance of an equilibrium position almost impossible, while removal of the prothoracic organs only partially reduced this ability.

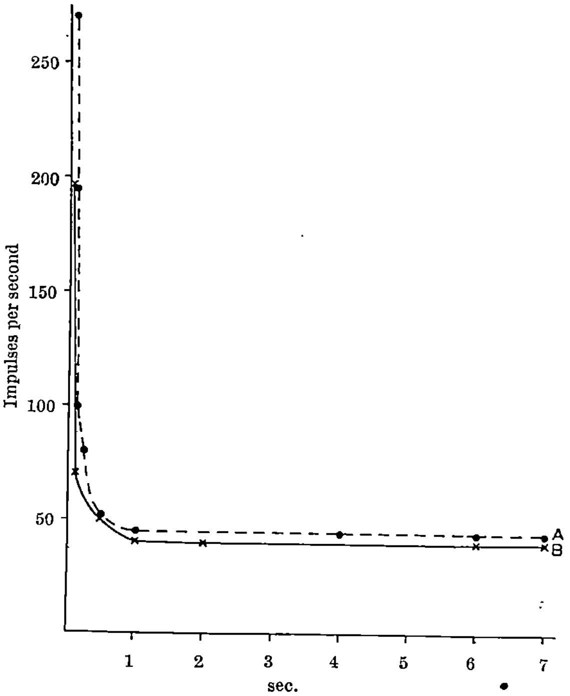

Fig. 1. Impulse frequency elicited by constant deflexion of single prothoracic hair receptor plotted against time after onset of stimulus; curve *A* resulted from a greater initial deflexion than for *B*

If the pronotal hair fringe is examined closely, it is found that it consists of a collar of upstanding, anteriorly sloped hairs which are only displaced by head movements in the dorso-ventral plane or by extreme angular rotations, and also a number of hairs on the underside of the edge of the pronotum which would appear to be displaced by any movement of the head relative to the body. Since the hairs in the collar-like fringe are deflected by wind when the locust is in flight, it would seem that proprioceptor functions in the air are carried out by the hairs under the edge of the pronotum. Histological preparations of the hairs (for which I am indebted to Miss K. M. Becker) show no apparent differentiation between the organs on the upper and under sides of the edge of the pronotum nor indeed from certain other, presumably tactile, hairs found elsewhere in the locust; the nerve fibre ending is apparently inserted at the centre of the hair, which accords with the fact that bending in any direction produces a response. This should be contrasted with the eccentric nerve insertion in campaniform sensillæ and in hairs responsive to bending only in one direction, noted by Pringle[3].

CHEMISTRY

Enhancement of Radiation-induced Cross-linking of Polyvinyl Chloride

The beneficial effects of ionizing radiation on certain polymers are well known. In the case of thermoplastics, such as polyethylene and polyvinyl chloride (P.V.C.), radiation-induced cross-linking confers insolubility and infusibility. Moreover, the tensile strength, elastic modulus and resistance to swelling increase progressively with the density of cross-linking. Many published studies have shown that the latter is approximately proportional to the radiation dose and largely independent of other factors such as radiation intensity[1]. In practice, fairly substantial doses in the range 10^7–10^8 rads are necessary to produce high densities of cross-linking. Radiation doses in the upper range are undesirable however, not only because of the current high cost of sources of radiation, but also because cross-linking is commonly accompanied by dislinking and other side-reactions, giving rise to impurities which may accumulate with the dose. This feature is particularly troublesome with polyvinyl chloride, in which cross-linking is accompanied by dehydrochlorination and discoloration[2].

These difficulties were early realized and have led to a search for additives which would enhance the cross-linking reaction. A true sensitizer is one that would increase the primary yield of cross-links, that is to say, enhance the interaction of radiation with the polymer. Neither theory nor practice encourages confidence that such a sensitizer may emerge. It is known, however, that high densities of cross-linking result from low doses when there is a possibility of a chain-reaction, as in unsaturated polyesters[3]. There is no increase in yield of primary radicals, but several network junction points may be created for each initiating radical during the propagation reaction, and the density of cross-linking is no longer solely proportional to the radiation dose.

A chain reaction could also be exploited with normally saturated polymers, like polyvinyl chloride, if these could be induced to suffer chain-transfer with a suitable propagating monomer *in situ*, for each chain-transfer step could lead to an additional junction point on the polyvinyl chloride. Recent studies on the polymerization of allyl esters have shown that these have a short propagation chain-length due to degradative chain-transfer, but that this process is accompanied by effective chain-transfer[4]. Diallyl and triallyl esters, moreover, are readily available and are compatible with polyvinyl chloride.

The rate of polymerization of pure allyl esters under irradiation by electrons or by γ-rays was found to be very low, compared with vinyl esters (Pinner, S. H., and Wycherley, V., unpublished work). The presence of polyethylene had little influence on the rate of conversion, but in the presence of polyvinyl chloride an extraordinary increase in conversion rates was observed over certain regions of composition.

This encouraged an examination of the products resulting from the irradiation of solid solutions of polyvinyl chloride in diallyl and triallyl esters, when they were found to exhibit the properties associated with a very high density of cross-linking. In Fig. 1, the swelling index (ratio of specimen weight after 24 hr. swelling in tetrahydrofuran at 20° C. to initial weight) is shown for solid solutions of polyvinyl chloride in a diallyl ester (open circles) and in a triallyl ester (solid circles) as a function of radiation dose, in comparison with the swelling index of unplasticized polyvinyl chloride 'Cobex' (square). The enhanced cross-linking of the polyvinyl chloride is further evident from the curves in Fig. 2, showing the tensile strength at 100° C. as a function of radiation dose for solid solutions of polyvinyl chloride in a saturated ester (crosses), in a diallyl ester (half-solid circles), and a triallyl ester (open circles) in comparison with the behaviour of 'Cobex' (solid circles).

A preliminary kinetic analysis of the rates of conversion of the allyl esters as a function of their concentration has indicated the inadequacy of a simple energy-transfer mechanism to explain the results. Coupled with the enhanced density of cross-linking of the polyvinyl chloride, the analysis suggests interaction of the polymer chains, not only with the propagating allyl radicals ($R.\mathrm{CH_2}$—$\dot{\mathrm{C}}\mathrm{H}$—$\mathrm{CH_2O}$—) but also with the resonance-stabilized allylic radicals ($\mathrm{CH_2}$=CH—$\dot{\mathrm{C}}\mathrm{H}$—O—). Reactivation of allylic radicals has been previously proposed to account for increased allyl polymerization rates at very high pressures[5].

The difference in behaviour between polyvinyl chloride and polyethylene may be attributed to the greater ease of abstraction of atoms from the chlorinated polymers, though questions of compatibility of the ester may also be involved. The efficacy of allyl esters probably arises from the short propagation chain-length and the accumulation of stabilized radicals, which renders the action of these monomers quite distinct from that of vinyl monomers, which

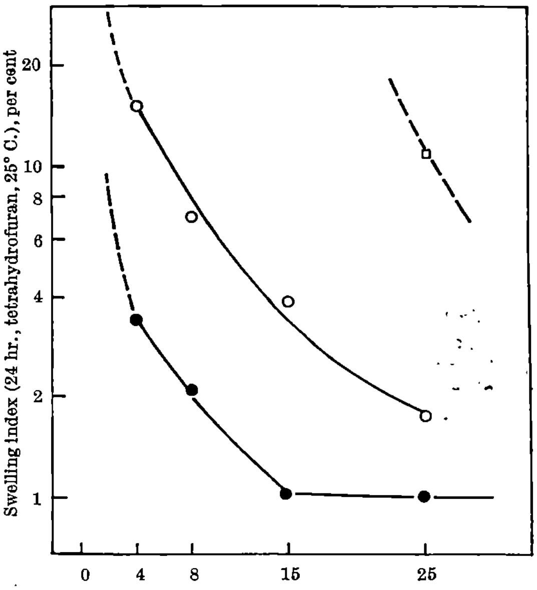

Fig. 1. Swelling of irradiated polyvinyl chloride

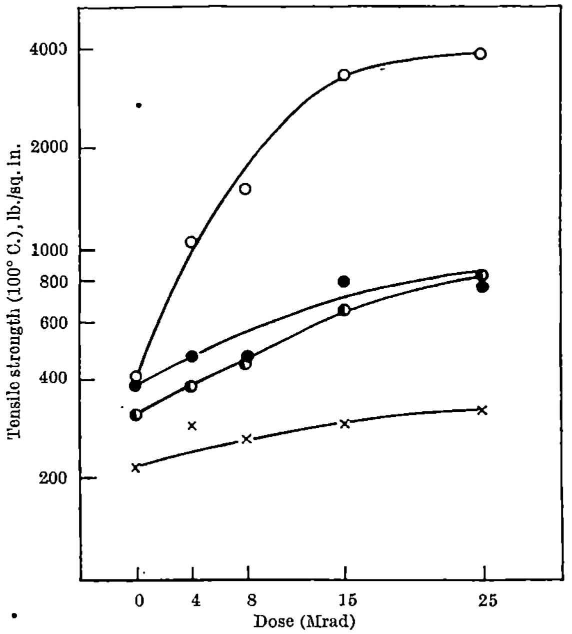

Fig. 2. Tensile strength of irradiated polyvinyl chloride

are also known to be polymerized *in situ* but without comparable involvement with the parent polymer.

Since highly cross-linked vinyl chloride copolymers are thus made readily available through the agency of allyl esters, it seems possible to regard these as 'promotors' for radiation-induced cross-linking, operating by a process of 'secondary initiation' (to distinguish it from primary initiation by the incident radiation) and giving a density of cross-linking much higher than that obtainable by radiation alone.

The kinetic data and theoretical implications of this work will be presented in greater detail in forthcoming publications.

I wish to thank Prof. A. Charlesby for his early interest and encouragement and colleagues at Hinxton Hall for discussions and experimental assistance. Part of this work was carried out in collaboration with B.X. Plastics, Ltd., and I thank the Chairman of B.X. Plastics, Ltd., and the Chairman of Tube Investments, Ltd., for permission to publish this account.

Adhesion and Ion-Exchange between Mica Surfaces

If the adhesive forces between mica surfaces[1] are due to ionic interactions as has been suggested[2], interchange of ions between two mica surfaces brought into contact might be expected. If matching of ions and sites in the aluminosilicate lattice were complete, we should find a redistribution of the surface ions between the two faces, and if the ion-site forces were the same for any given ion with respect to both sheets, this new configuration should find half the ions from each sheet transferred to the other. Such an exchange has now been found to occur by observing the transfer of radioactive potassium-42 from a mica sheet on to which it had been exchanged from aqueous solution[3] to another sheet initially inactive. When such an experiment was performed by simply pressing the two sheets of mica together on a flat surface, the amount of activity transferred was only 10 per cent of that initially present. This would suggest that the sheets were in contact over only 20 per cent of their area. This result is in line with the initial transfer values for stearic acid monolayers between mica surfaces pressed together, as found by Rideal and Tadayon[4]. When the area of intimate contact was observed by multiple-beam interference techniques, however, the amount of transfer was found to be nearly half the total exchangeable potassium in that area.

Sheets of silvered mica were prepared and used for contact area measurement by the methods described by Bailey and Courtney-Pratt[5]. After cleaving the silvered sheets, and before the pieces were put into contact, the unsilvered side of one piece was rinsed with a 10^{-3} *N* potassium chloride solution containing potassium-42, rinsed with acetone, and dried. The two pieces of mica were then inserted in the clamps and brought into contact under the microscope. The area of uniform tint was measured with a micrometer eyepiece, the strips were then separated (total contact times were 2–8 min.) and the central portion of each, which included the contact area, was cut out and its activity measured under an end-window Geiger–Müller counter. (The area of contact was always a negligible fraction of the total area of the counting sample.) The results are collected in Table 1. Since the mica sheets were not especially selected for thickness, the sensitivity of the contact area measurement was not high nor necessarily reproducible. Especially in the case of the smaller contacts, where the activity transferred was also small, the observed values may be in considerable error. It is apparent, however, that the amount of potassium-42 transferred was very nearly half that initially present on the exchanged sheet. That initial activity, furthermore, was in satisfactory agreement with the activity calculated for complete surface potassium exchange with the solution used (1,300 counts/min./cm.^{2}).

Derjaguin *et al.*[6] have proposed a charge separation mechanism to account for their (rather higher) observed cleavage energies of mica. There seems to be no reason why surface potassium ions distributed in patches might not be invoked to provide their charge mosaic. As they suggest, the forces between such patches would still be large at appreciable separation of the sheets and would lead to gas dis-

Table 1. Observed Potassium-42 Activity on Contacted Mica Sheets

charge. At the higher rates of cleavage which they used, moreover, such behaviour may be more likely than if the cleavage occurs as a nearly equilibrium process. (This point has been brought out by Miss Bailey[7].) The present experiments, of course, cannot distinguish between a uniform distribution of potassium ions and an array of small patches, and therefore I am not able to evaluate the importance of this contribution.

I am greatly indebted to Miss C. P. Rutkowski for experimental assistance and to Dr. David Tabor for interesting discussions.

Material Transfer in Monomolecular Layers of a Boundary Lubricant

Bailey and Courtney-Pratt[1] have studied the shearing of monomolecular layers of calcium stearate between flat mica sheets. They concluded that this shearing in the boundary lubricant film, which may afford almost perfect protection against wear, still contributes significantly to sliding friction. The processes which occur in the contact of such atomically flat surfaces protected by boundary films are therefore of some interest. It has been shown that mica surfaces brought into contact interchange the exchangeable potassium ions on their surfaces (preceding communication). This observation seems to support the postulate that the adhesive force between mica surfaces is ionic in nature[2]. Rideal and Tadayon[3] observed transfer of stearic acid from monolayers deposited on mica to other mica surfaces, but the major portion of their work seems to have been concerned with surface diffusion processes rather than true contact transfer.

In this communication the results of some preliminary measurements of area of true contact and transfer of stearic acid from monolayers, as well as migration of surface potassium ions through such monolayers are reported. The methods of Bailey and Courtney-Pratt[1] were used to measure contact areas and the potassium ion transfer was detected with potassium-42, as in the previous communication. Potassium ion migration was observed from an ion-exchanged mica surface[4] to a sheet of mica coated with a monolayer of commercially pure stearic acid (Armour 'Neo-Fat 18'). Stearic acid transfer was observed by measuring the activity transferred from a mica surface coated with a monolayer of stearic acid labelled with carbon-14 at the carboxyl group to an untreated surface. In both types of experiments, monolayer deposition was accomplished by the Blodgett technique[5], using a distilled water substrate and a surface pressure of about 30 dynes/cm. (oleic acid piston oil). The stearic acid was spread from hexane solution. The results of the transfer measurements are recorded in Table 1.

Table 1. TRANSFER OF POTASSIUM-42 AND STEARIC ACID-^{14}COOH BETWEEN MICA SURFACES

A. Potassium ion transfer in the presence of a stearic acid film

	Potassium-42 exchanged sheet, observed (c./min./cm.^{2})*	Contact area (cm.^{2})	Contacted sheet (c./min.) obs.*	Transferred activity (c./min./cm.^{2})
1	290 (10)	0·052	11·2 (2·8)	214
2	1,100 (15)	0·092	20·6 (1·8)	224
3	900 (10)	0·002	1·7 (1·6)	850

(Samples 2 and 3 from a different lot of potassium-42 than sample 1.)

B. Stearic acid–^{14}COOH transfer.

	Monolayer-coated sheet, observed (c./min./cm.^{2})*†	Contact area (cm.^{2})	Contacted sheet (c./min.) obs.*	Transferred activity (c./min./cm.^{2})
1	313 (3·0)	0·093	6·2 (0·5)	67
2	—	0·0051	1·5 (1·1)	294
3	—	0·016	1·1 (1·0)	68
4	—	0·018	2·0 (1·1)	111

* Counting standard deviations in parentheses. All counting-rates corrected for background, counter resolving-time and decay, where appropriate.

† Samples 1–3 were all coated from the same spread monolayer. Sample 4 was a separate monolayer spread from the same solution.

It is apparent from Table 1 that these results obtained are very crude and must be considered as preliminary. It is, however, clear that some transfer of both stearic acid and potassium ion does occur. Whether transfer of potassium ions occurs here through formation of a soap and migration of the entire soap molecule cannot be decided on the basis of the present results—radioactivity measurements of higher precision (which would require reagents of higher specific activity than were at hand in this work) would be needed to decide this point. The interesting differences in diffusion transfer of monolayers observed by Rideal and Tadayon make this point of some interest in connexion with the processes occurring in boundary lubricant layers. The ability of molecules to move from monolayers on one member of a sliding couple to the other member will be important in the protection of the surfaces, and the possibility of transferring metallic ions either through the monolayer or in conjunction with overturning lubricant molecules must be recognized.

I am indebted to Miss C. P. Rutkowski for assistance with these experiments.

A New Method of Integration Recording

The method now commonly used for recording continuously and in real time the integral of an instrument output signal requires the counting of pips in the final record. It is therefore essentially digital in nature. We have devised in our laboratory an analogue method (patents applied for) that eliminates counting and produces a new form of record, an 'integram', that appears to be particularly interesting and useful for gas chromatography.

The general scheme of the method is shown in Fig. 1. A conventional pen servo responsive to the signal drives the pen across the chart in the usual

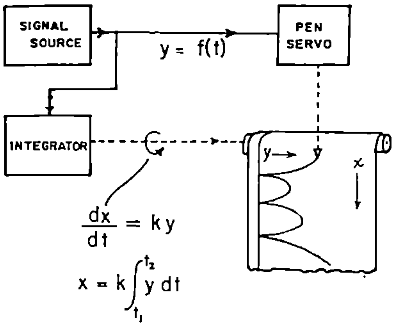

Fig. 1

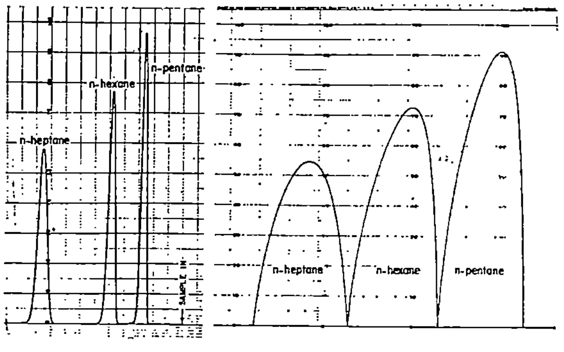
way. The distinctiveness of the technique lies in the manner of driving the chart, namely, at a rate proportional to the recorded signal. By definition, the required chart drive mechanism is a form of integrator.

The familiar ball-and-disk integrator, with its input shaft driven by the pen transport mechanism and its output coupled to the chart drive, would appear to answer the practical requirements quite well and could be the basis of a relatively low-cost system. In the apparatus we actually employed to make the recordings shown, however, it was expedient to use a velocity servo type of integrator[1]. We inserted a conventional attenuator between the signal source (the gas chromatograph detector) and the pen servo, and a second attenuator (for signal reduction in ratios of 1 : 5 : 20) between the output of the first attenuator and the integrator. The velocity servo comprised a high-gain amplifier driving a motor and a direct-current tachometer. The tachometer output, fed back inversely to the servo-amplifier input, caused the servo output shaft, and thus the chart, to be driven at a rate proportional to the servo input signal.

The separate attenuator at the input of the velocity servo is necessary because the duration of gas chromatography peaks may vary over a considerable range: 20 to 1 or more. Thus, when peaks occur that are long lasting and also of large amplitude, the chart speed per unit of pen deflexion may be reduced to avoid excessive run-off of paper. As an auxiliary paper-saving feature, a switch may be mounted on the recorder whereby the pen drive at the upper limit of travel short-circuits the input to the servo-amplifier. The chart is thereby arrested during intervals when the pen is off the scale. Integration information is, of course, lost during such intervals, but in this respect the system does not differ from other recorder-coupled integrating devices.



(*a*) (*b*)

Fig. 2. (*a*) Chromatogram and (*b*) integram. Sample: 0·02 ml. *n*-pentane, *n*-hexane and *n*-heptane (1 : 1 : 1); chromatogram chart speed, 0·5 in./min.; integram chart speed, 8 in./min./100 per cent signal; column, 6 ft., silicone 550, 40–60 *C*-22 firebrick; temperature, 91° C.

For change-over at any time to conventional chromatographic recording, it is necessary only to operate a switch that substitutes a constant voltage at the input of the servo-amplifier in lieu of the gas chromatographic signal, so that the chart is driven at constant speed.

Fig. 2*b* shows a typical integram. The corresponding conventional chromatogram is shown in Fig. 2*a*. The records shown were run simultaneously on a sample of equal parts of *n*-pentane, *n*-hexane and *n*-heptane. (The discrepancy between corresponding peak heights in the two recordings is due to an inexact divider used at the input of the integram recorder.)

Of primary interest is the property that the base width of each peak in the integram is proportional to the area of the corresponding chromatogram peak.

Thus, the integram shows at once that the components are approximately equal in quantity, a fact not easily discerned in the conventional recording. We note, too, that the integram contours terminate sharply in the base line at well-defined points and with steep slopes, whereas 'skirts' tapering gradually to zero slope appear in the corresponding chromatogram. This has been found to be true even when extensive tailing occurs. The integram therefore clearly defines the integration limits. As a note of interest, the property of sharp termination applies equally to a variety of functions (of signal vs. time) that might be encountered in instrumental measurements, for example, Gaussian distributions, exponential decay and displaced sinusoidal functions such as $y = 1 + \sin \omega t$.

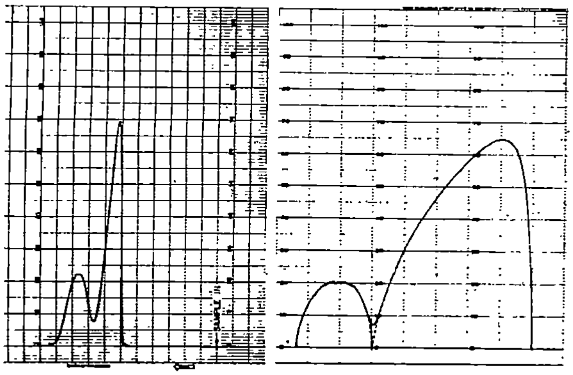


Fig. 3. Incompletely resolved peaks. Sample, 0·03 ml., methyl ethyl ketone and *cyclo*hexane (2 : 1). Conditions as in Fig. 2

Fig. 3 shows an example of the curves obtained on incompletely resolved components. Without prior knowledge of the peak shapes, it would be pure guesswork to extrapolate the overlapping curves in the chromatogram at the left in order to determine individual integration limits. In the corresponding integram, however, extrapolation is much more reliable. Given the degree of resolution shown, we can predict with some confidence (especially for the larger peak) where the extrapolated curves would meet the axis. Experience indicates that the shape of the integram for a given component remains quite characteristic and exhibits no surprising changes of direction as it approaches the axis. Thus a French curve laid against the integram contour can give a useful extrapolation. A point of special interest is that, having extrapolated one of the adjoining, unresolved peaks, we resolve also the uncertainty for the other, because in the integram both extrapolations join the axis at a common point. This follows from the fact that total integram base-width for adjoining peaks is proportional to the sum of the separate integrals and independent of degree of resolution (on the reasonable assumption that detector response is linearly additive for superposed components).

Characteristically, the integram does not indicate elapsed time. Thus the integram of Fig. 2 does not tell how long the signal remained at zero between peaks, or the times at which the maxima occurred. A simple adaptation of the recorder, however, furnishing a supplementary time trace, permits this information to be embodied in the record. The integram may, for example, be confined to half the chart width (without serious loss of accuracy since the quantitative information of interest resides mainly in the width of the integram peaks, not their heights). A second pen is then provided which is driven laterally across the other half of the chart at a suitable constant speed. The supplemental trace thus obtained completely correlates the events of the integram with elapsed time, exhibiting plateaux in the lateral chart direction during the time intervals between peaks, and inflected steps between the plateaux marking the chromatogram peaks.

This work was announced at the Pittsburgh Conference on Analytical Chemistry and Applied Spectroscopy on March 6, 1958.

PHYSICAL SCIENCES

Conductivity induced by Radiation in Polycrystalline Cadmium Sulphide and Polyethylene

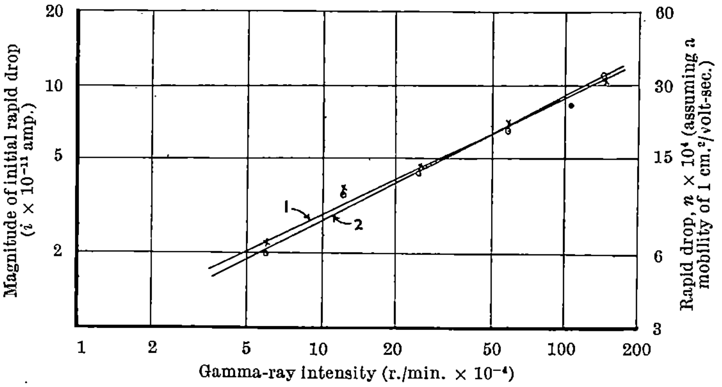

Fig. 1. Two crystals, (1) and (2), of polycrystalline cadmium sulphide at −55° C.

When ionizing radiation falls on insulating or semiconducting solids, there is an increase in electrical conductivity resulting from the production of electron-hole pairs. If the source of ionizing radiation is removed, the conductivity decreases at a rate dependent upon the release of electrons from traps into the conduction band.

For any system with a continuous distribution of traps, it has been shown[1] that the curve of conductivity decay following excitation by radiation is approximately hyperbolic, and is given by the equation:

$$\frac{1}{n} = \frac{1}{n_0} + \frac{(m)}{(M_E)} \frac{bt}{kT} \qquad (1)$$

where n is the number of electrons per unit volume in the conduction band at any time t after removal of the exciting radiation and n_0 is the value of n at $t = 0$; b is the recombination coefficient of electrons with the original centres; m is the number of trapped electrons per unit volume and M_E is the number of traps per unit volume per unit energy-range. The departure from hyperbolic decay in cadmium sulphide has been used by Broser and Broser-Warminsky[2] to calculate the detailed distribution of traps in depth.

This theory leads one to believe that if thermal equilibrium between electrons in the conduction band and those in traps is not valid, as would occur if the rate of release from traps were smaller than the rate of recombination, a rapid drop in current would be observed until the rates became comparable. Thereafter equation 1 would be followed. The time constant for this rapid decay is of the order of $1/bm$. The time constant of the main decay following the rapid fall is of the order of $1/bn_0$; that is, larger than the rapid decay by the ratio m/n, approximately.

We have obtained support for this aspect of the theory from observations of an initial rapid decay in cadmium sulphide and in polyethylene under irradiation by gamma- and X-rays, respectively. Although these substances have conductivities which differ by orders of magnitude, the mechanism of induced conductivity is expected to be the same. Both substances normally show a similar dependence of induced conductivity on dose-rate, namely:

$$\sigma \propto R^{0.85} \qquad (2)$$

where R is the dose-rate.

There are two conditions for which an excess of conduction electrons would be present to cause this initial rapid drop. One is at extremely high intensities of radiation, where the concentration of free carriers, n, would be larger than the concentration of trapped electrons, m; that is, larger than 10^{14}–10^{17} per cm.^{3}. This condition would occur at radiation intensities of the order of megarads per minute. The second condition is found at temperatures sufficiently low to delay significantly the thermal release of electrons from traps, that is, at temperatures below −10° C. in cadmium sulphide, and at room temperature (20° C.) in polyethylene.

Under the conditions described, where an initial rapid drop is observed, the traps are not effective, so that the dependence of steady-state induced conductivity on radiation intensity should follow instead a simple square root relationship:

$$\frac{dn}{dt} = 0 = Q - bn^2$$

$$\text{or,} \qquad n \propto Q^{1/2} \qquad (3)$$

where Q is the ionization-rate per cm.^{3}.

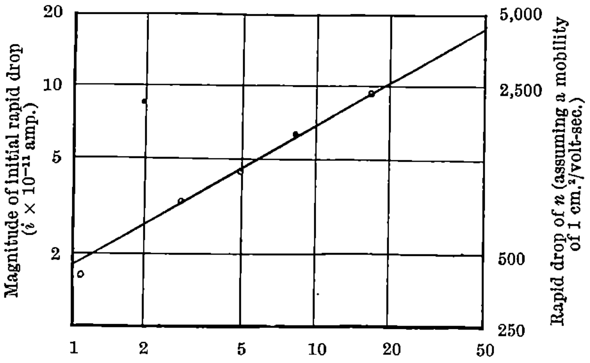

Fig. 2. Polyethylene at + 20° C.

We find experimentally that this is so to a reasonable degree of accuracy.

Fig. 1 shows curves relating to cadmium sulphide in which the logarithm of the magnitude of the initial drop has been plotted against the logarithm of the radiation intensity, yielding an exponent of 0·48 in equation 3. Fig. 2 shows similar curves for polyethylene, where the exponent is 0·56.

For substances with an exponential distribution of traps, Rose[3] gives the variation of induced conductivity with dose-rate and temperature as :

$$\sigma \propto R^{T_1/(T+T_1)} \qquad (4)$$

where T_1 is a constant of the substance which has the dimension of temperature, and which has been suggested as being the 'trap melting point'. Both these substances have values of T_1 about 1,500° K., and it has been shown[2] that for substances having such high values of T_1 an initial drop is more likely than for substances having a lower value of T_1, approaching room temperature.

Support is therefore afforded for the conception of photo-conductive trapping and decay as applied to ionizing radiation falling on insulating or quasi-insulating substances.

We are indebted to Dr. S. T. Henderson, Thorn Electrical Industries, Ltd., for supplying the polycrystalline cadmium sulphide layer cells.

Refractive Index of Uranium Oxide produced by Anodic Oxidation

During a study of the anodic oxidation of uranium it was found that brilliant interference colours could be obtained using an aqueous solution of ammonia as electrolyte. The film was found to be non-absorbing up to the maximum voltage which could be applied without pitting of the metal, that is, 270 V. Flint *et al.*[1] have studied the anodic oxidation of uranium in various electrolytes and consider that ammoniated ethylene glycol only can be used for producing interference films without pitting.

It was considered that, providing the refractive index could be determined, the kinetics of film growth could be studied with advantage by an optical reflectivity method. Separation of the anodic oxide from the metal was not possible, and the bulk oxide could not be used for this determination since the chemical and physical nature of oxide films produced by anodic oxidation usually differs from oxides prepared thermally or chemically.

An investigation of the solubility of the anodic oxide revealed that it dissolved readily in dilute sulphuric acid, which, however, did not attack the underlying metal. It was thus possible to remove the anodic oxide film completely from part of the specimen, forming a sharp oxide step which could be measured, after silvering, by multiple beam interferometry using reflected light[2]. It is of interest to observe that this method is not applicable to the refractory anodic oxides produced on tantalum, zirconium, niobium and titanium.

The refractive index calculated using this method gave $\mu = 1·93$.

The above technique has, however, been extended to provide a method which is applicable even if the metal is slightly soluble in the acid since, by suitably controlling the dissolution of the oxide in the acid, a wedge of oxide could be produced on the metal surface. An examination of this oxide wedge revealed dark fringes, in the direction of the wedge length, which corresponded to successive orders of interference minima in the oxide. The specimen was suitably mounted in conjunction with a silvered reference flat so that a further fringe system was produced at right angles to the fringe system in the oxide wedge. A composite fringe system was thus obtained in which the multiple-beam fringes became laterally displaced in crossing the wedge. By means of an eyepiece micrometer the intersection of these fringes with the order fringes could be located.

The fringe system is shown diagrammatically in Fig. 1, where *aa* represents order fringes in the oxide wedge and *bb* multiple-beam fringes formed between the flat and specimen. The physical thickness of the oxide between successive interference minima is $\lambda/2\mu$, where μ is the refractive index of the oxide and λ is the wave-length of the light source.

The displacement d of fringe *bb* in passing between adjacent minima *aa* corresponds to an increase in optical path of λ/μ, and the distance D between

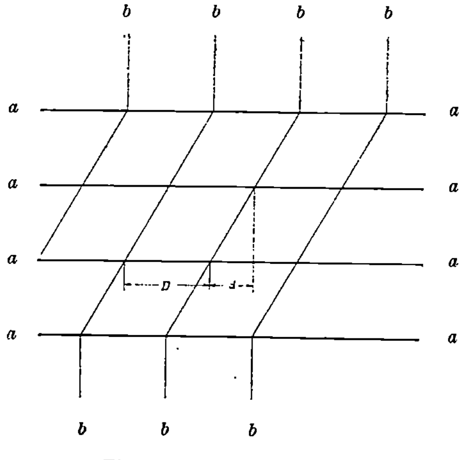

Fig. 1. Composite fringe system

successive *bb* fringes corresponds to change in optical path of λ. Hence,

$$\mu = \frac{D}{d}$$

An average value of several determinations embracing four orders of interference gave $\mu = 1{\cdot}95$ for uranium oxide produced by anodic oxidation.

This value is in good agreement with the value for the refractive index determined by the previous method. The accuracy of the determination was limited by irregularities in the metal surface and by the broad fringes obtained, and it was not possible to determine whether μ varied within the thickness of the oxide wedge.

A determination of the refractive index of thermally prepared uranium oxide by Brewster angle measurements on the polished face of a sintered block gave a much higher value, namely, $\mu = 2{\cdot}26$ for uranium oxide produced thermally.

Using the value $\mu = 1{\cdot}95$, the growth-rate of the oxide during anodizing in ammonia solution was found to be 28 A./V.

Frequency of Meteorite Falls throughout the Ages

As recently as in 1956 the late Prof. F. A. Paneth, an authority on meteorite investigations, published a paper under the above heading[1], in which he wrote: "iron and stone meteorites did not fall before the late Quaternary".

Thanks to studies carried out here in Sweden on the 'cosmic spherules' discovered by J. Murray in 1876 [2], which are present in the long cores of sediment raised from great ocean depths by the Swedish Deep Sea Expedition in 1947–48 by means of the Kullenberg piston-core sampler[3], we are now able to refute this hypothesis. We have been able to extract from the sediments cosmic spherules identical with those described by Murray but in much greater numbers, from tens to a couple of thousands per kilogram of red clay[4,5]. Also in the deepest sections of cores from the Pacific Ocean, dating back to the Tertiary Age, such spherules were found. It is to be hoped that by more extensive investigations of this kind a new chronology for deep-sea deposits may be evolved, going back much further in time than is possible by means of radioactive measurements.

This communication (detailed papers are being prepared) is chiefly meant to be a plea for studying the cosmic spherules present in long cores of sediment which will be obtained by future deep-sea expeditions. In case the plans for drilling a hole through the deep-ocean sediments down to the underlying bedrock, repeatedly referred to in *Nature*[6], are realized, a study of the cosmic spherules present in the different layers penetrated will afford a unique record of the variations in meteor frequency since the oceans came into existence. This result alone will make it eminently worth while to realize the grandiose project, the total costs of which will amount only to a fraction of the costs of sending a manned rocket to the Moon.

Chemical Composition of Tektites

In a recent communication, Brian Mason[1] asks that I supply a list of chemical compositions of sedimentary rocks which parallel those of the tektites. I offer the following references for his samples of tektites labelled A_1–G_1. The pages in the following list refer to Pettijohn's book on sedimentary rocks[2]: A_1, 298; B_1, 364; C_1, 319; D_1, 319; E_1, F_1 and G_1, 306. Except for water content, fair agreements between analyses can be secured by selecting analyses from these tables. The low water content of tektites is a real puzzle. There are some small differences in analyses between those listed by Pettijohn and the tektites. It is very probable that some granites of the composition listed by Mason are fused sediments. What would be more interesting than an argument about average sedimentary rocks would be a comparison of the composition of particular groups of tektites and sedimentary or igneous rocks in the general area in which the tektites are found. If cometary collisions melted the local rock and scattered the fragments over great distances[3], it should be possible to find the original material at an appropriate place. But this requires study by an expert in these matters and probably additional observational data, and these cannot be supplied by me.

BIOCHEMISTRY

Are Nucleoside Triphosphates Precursors of Mammalian Ribonucleic Acid *in vivo*?

When albino rats are kept for 6–7 weeks on a protein-free diet they lose about half their body-weight[1]. At the same time, almost 50 per cent of the liver proteins and ribonucleic acid disappear: this can only be explained by a decrease in their biosynthesis.

We have studied the liver supernatant, because in this particular fraction loss of nucleoside di- and tri-phosphates during differential centrifugation can be prevented by the addition of ethylenediamine tetraacetate to the separation medium, whereas nucleoside polyphosphates are hydrolysed to monophosphates in the mitochondria and microsomes.

Protein deprivation results in the disappearance of 56 per cent of the proteins and 36 per cent of the ribonucleic acid in the supernatant, while there is an accumulation of adenosine triphosphate (4·7 times the control), guanosine and uridine triphosphates.

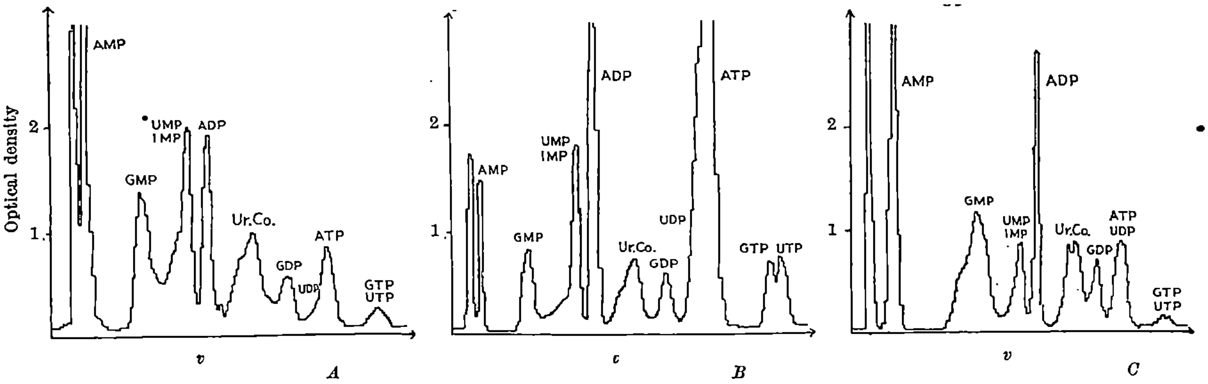

Fig. 1. Free nucleotides of rat liver supernatant, separated on a column of 'Dowex' 1×8, 200–400 mesh, 0·8 cm. × 30 cm. Gradient elution through formic acid and formic acid – ammonium formate: *A*, controls; *B*, deprived animals; *C*, protein deprivation followed by normal feeding

Note the increased ATP, GTP and UTP (adenosine, guanosine and uridine triphosphates) peaks after protein deprivation, and the return to normal when rats are fed normally for three days after six weeks protein deprivation.
Optical density measured at 2600 A. in a 1-cm. cuvette; *v*, eluant volume; *Ur.Co*, uridine coenzymes

No cytosine triphosphate could be detected in our experimental conditions either in controls or in deprived animals. This increase of nucleoside triphosphates, parallel with the reduction in the synthesis of ribonucleic acid, suggests that these nucleotides are the precursors of ribonucleic acid. The decrease of ribonucleic acid in the supernatant cannot be due to absence from the diet of the amino-acids glycine, glutamic acid and aspartic acid, precursors of the purine and pyrimidine rings, since these amino-acids are not indispensable.

The results show, for the first time in the case of mammals *in vivo*, that the synthesis of ribonucleic acid is dependent on the synthesis of protein: after protein deprivation, we find a drop in proteins and in ribonucleic acid but an accumulation of nucleoside triphosphates in the supernatant; when rats, deprived of proteins for six weeks, are afterwards fed normally for three days, a rapid increase in proteins occurs, which is paralleled by that of ribonucleic acid, while the nucleoside triphosphates revert to normal levels.

We also incubated whole liver slices of controls and deprived animals for 20 min. at 37° C. with or without a complete mixture of amino-acids. These amino-acids are without effect on the incorporation of phosphorus-32 into ribonucleic acid in the controls. In the case of deprived animals, in which the pool of free amino-acids is certainly small, incorporation of phosphorus-32 is considerably enhanced by the addition of the amino-acid mixture. This suggests that the syntheses of protein and of ribonucleic acid are concurrent processes (which we are now trying to prove by the use of amino-acids labelled with carbon-14). No net increase in the quantity of ribonucleic acid can be detected in such a brief time of incubation, but the greater incorporation of phosphorus-32 seems to afford sufficient evidence. The fact that the ribonucleic acid fraction remaining after protein deprivation shows a greater incorporation (*in vivo* as well as *in vitro*) is discussed elsewhere[2].

Table 1. INCORPORATION OF PHOSPHORUS-32 INTO RAT LIVER RIBONUCLEIC ACID *in vitro*

Whole liver slices were incubated for 20 min. at 37° C. with or without a complete mixture of amino-acids. Values are in c.p.m. per 100 μgm. of ribonucleic acid phosphorus

Experiment No.		Without amino-acids	With amino-acids
1	Controls Deprived animals	490 2,610	570 4,550
2	Controls Deprived animals	400 2,060	520 3,560

In other words, while it appears to be well established that ribonucleic acid is indispensable in protein synthesis, it also seems that little or no ribonucleic acid is synthesized when protein synthesis is stopped or at least slowed down by deprivation of nitrogen. This agrees with facts observed in micro-organisms[3]. In any event, it seems highly improbable in the light of present knowledge that the cell should synthesize proteins on one hand and ribonucleic acid on the other, both of which would afterwards combine to form specific nucleoproteins. The synthesis not of proteins and ribonucleic acid separately but of nucleoproteins from amino-acids and nucleotides would explain the known facts, namely, the role of ribonucleic acid in protein synthesis and vice versa. This synthesis of ribonucleoproteins may occur by condensation of nucleotide – amino-acids complexes. Hitherto, only adenosine monophosphate–acyl complexes have been described. Our hypothesis postulates the existence of guanosine, uridine and cytosine monophosphate complexes. The fact that these complexes have not so far been discovered does not constitute proof that they do not exist.

This hypothesis might be extended to other classes of heteroproteins. Hendler[4] recently reported that lipids play a part in the synthesis of proteins. It is possible that synthesis of certain lipoproteins occurs through condensation of amino-acid – lipid complexes, and that of some glycoproteins by condensation of amino-acid – saccharide complexes.

Stizolobic Acid : a New Amino-Acid in *Stizolobium hassjoo*

Two new amino-acids have been found in the sap exuded from the cut surface of the epicotyl tips of etiolated seedlings of *Stizolobium hassjoo*, all parts of which turn black on dying owing to the oxidation of 3,4-dihydroxyphenylalanine. The exudate contains 3,4-dihydroxyphenylalanine and two new amino-acids, as shown by paper chromatography. The R_F values of the latter amino-acids coincided with no amino-acids already known, and it is proposed that these compounds be named stizolobic acid and stizolobinic acid, respectively. Stizolobic acid gives rise to an orange spot with ninhydrin ($R_F = 0 \cdot 16$ in phenol/water (8 : 2 w/w), 0·11 in *n*-butanol/acetic acid/water (4 : 1 : 2 v/v)), while stizolobinic acid gives a brown spot ($R_F = 0 \cdot 24$ in phenol/water, 0·14 in *n*-butanol/acetic acid/water).

Stizolobic acid was isolated from the combined exudates by ion-exchange column chromatography (*IR*–4*B*—0·05 *N* hydrochloric acid displacement) and obtained as colourless needles, which melted at 231–233° C. after recrystallization. Since the content of stizolobic acid in the plant is very small, the yield from about 10 kgm. seeds was only 10 mgm.

The empirical formula of stizolobic acid was found to be $C_9H_9O_6N$ (found: C, 47·91; H, 3·96; N, 6·45 per cent; calc.: C, 47·62; H, 4·00; N, 6·17 per cent). All nitrogen belongs to amino group as measured by van Slyke's method (found amino-nitrogen, 6·05 per cent). It was shown to contain an α-amino group by its complexing with copper[1], and to be an acidic amino-acid by paper electrophoresis. The results of alkaline titration of the carboxyl group in 90 per cent ethanol showed that it was possibly a dibasic acid. Addition of bromine was not successful, and attempted reaction with carbonyl reagents was also unsuccessful. However, stizolobic acid was attacked by ozonolysis and absorbed about 2·5 mol. hydrogen on catalytic hydrogenation in the presence of a palladium–carbon catalyst, yielding two products, both of which were acidic amino-acids and gave purple spots with ninhydrin. One of them, which was a major product when hydrogenation was interrupted soon after 2 mol. per cent had been absorbed, reacted with 2,4-dinitrophenylhydrazine to form yellow crystals. These properties made it probable that stizolobic acid itself might have a special type of carbonyl group or groups and two —C=C— bonds, and led us to suppose the presence of a γ-pyrone nucleus.

Many γ-pyrone compounds absorb 2–3 mol. hydrogen on catalytic hydrogenation, producing tetrahydro-γ-pyrone compounds and tetrahydro-γ-pyranol compounds, the former reacting with carbonyl reagents[2]. If a γ-pyrone is assumed to be present as an integral part of stizolobic acid, it would readily explain the fact that the carbonyl group does not show ordinary addition reactions, and suggest that the two products are probably a tetrahydro-γ-pyrone compound and tetrahydro-γ-pyranol compound.

The analysis of infra-red spectra of stizolobic acid and its deuterated product gave further support for the γ-pyrone structure of stizolobic acid (Fig. 1). From the data, considering chemical properties, the presence of the following groups could be deduced: NH_3^+, COO^-, non-ionized COOH group (another carboxyl group), two or more H atoms in $=\overset{\mathrm{H}}{\overset{|}{\mathrm{C}}}-$ groups and one or more —C=C— groups probably conjugated with a —C=O group. The spectra are also not inconsistent with the presence of a =C—O—C= group.

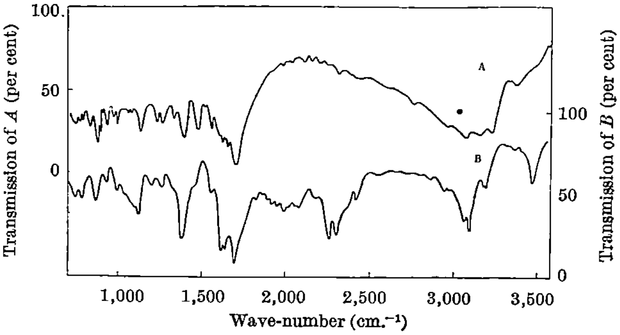

Fig. 1. *A*, Infra-red spectrum of stizolobic acid. Solvent: hexachlorobutadiene (1,300–1,500 cm.$^{-1}$); *B*, infra-red spectrum of its deuterated product. Potassium bromide disk (750–1,800 cm.$^{-1}$). Solvent: hexachlorobutadiene (1,800–3,500 cm.$^{-1}$)

Ozonolysis of stizolobic acid gave aspartic acid, oxalic acid and formic acid. Aspartic acid was also produced on oxidation with potassium permanganate. From these results it seemed likely that stizolobic acid might contain $=CCH_2CH(NH_2)COOH$, $=CCOOH$ and $=CH$ groups. Considering the possible presence of the γ-pyrone nucleus, the structure of stizolobic acid might be assumed to be β-(carboxy-γ-pyronyl)-alanine.

Degradation with boiling 3*N* sodium hydroxide for 3 hr. gave glutamic acid as a major ninhydrin-reacting product and malonic acid, oxalic acid and another unidentified acid as non-volatile organic acids, and formic acid. No acetone was detected. From the examples of alkaline degradation of chelidonic acid[3], comanic acid[4], 2,6-dimethyl-γ-pyrone-3,5-dicarboxylic acid[5] and other γ-pyrone compounds[2,6], formation of glutamic acid by the alkaline degradation of stizolobic acid indicates that the side-chain $—CH_2CH(NH_2)COOH$ might be not on the C_2- or C_6-position, but on the C_3- or C_5-position. Formation of formic acid suggests that there might be no substituent on the C_2- and/or C_6-position, and since malonic acid is produced, the position of the carboxyl side-chain could not be deduced to be attached to other than the C_3- or C_5-position.

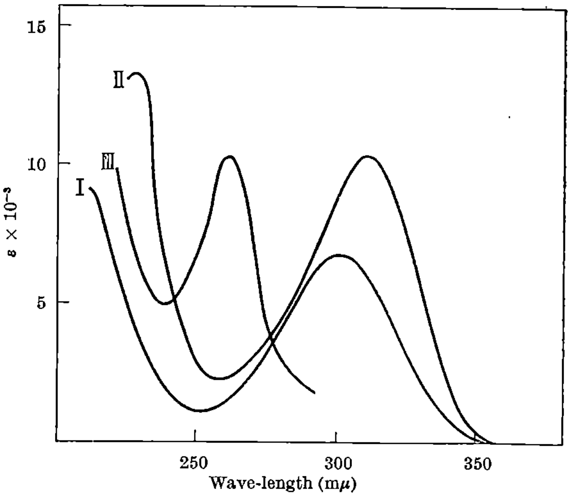

Fig. 2. Ultra-violet spectra of I, stizolobic acid; II, dihydro-acetic acid; III, comanic acid

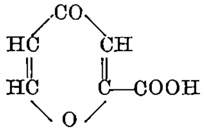
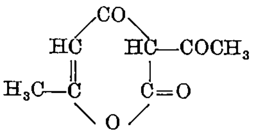
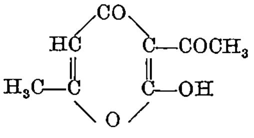
Some evidence of the position of the carboxyl side-chain is provided by the ultra-violet spectrum. Assuming that stizolobic acid has a carboxyl group as side-chain on the C_2- or C_6-position of the γ-pyrone nucleus, its ultra-violet spectrum might be similar to that of comanic acid (I). However, the spectrum of the former ($\lambda_{max.} = 300$ mμ) differs from that of the latter ($\lambda_{max.} = 260$ mμ), but is similar to that of dehydroacetic acid (II, $\lambda_{max.} = 310$ mμ), which exists as a virtually completely enolized species in solution[7] (Fig. 2). As this form (II*a*) is similar from the point of view of ultra-violet absorption to the postulated structure of stizolobic acid (III), excepting that there is a —OH group on the C_2-position in (II*a*), which would be expected to shift the maximum of the spectrum by 10–20 mμ to longer wave-length, the postulated structure of stizolobic acid is not inconsistent with ultra-violet absorption data.



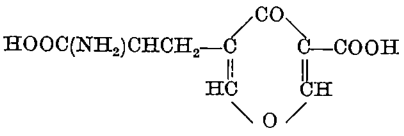
(I)



(II)



(II*a*)



(III)

The results of electrophoresis indicated that stizolobic acid is a considerably stronger acid than other monoamino-dicarboxylic acids such as aspartic acid. This finding confirms the assumption that the side-chain of a carboxyl group might be on either the C_3- or C_5-position in the γ-pyrone nucleus, both of which would be expected to enhance the acidity, while a carboxyl group on the C_2- or C_6-position would be expected to show a weak acidity, because of a proton-attractive —O— group.

From all the evidence described above, it appears that stizolobic acid has the structure β-(3-carboxy-γ-pyron-5-yl)-alanine. In recent years a number of new, unusual amino-acids have been isolated from plant materials; but an amino-acid with a γ-pyrone nucleus such as stizolobic acid has not been found hitherto. It has been shown to be present in the various organs of *Stizolobium deeringianum, S. hassjoo, S. pruriens, S. utilis* and *Mucuna irukanda,* but it could not be detected in seeds of *Arachis hypogaea, Azukia angularis, Canavania gladiata* var. *alba, Glycine max, Phaseolus vulgaris, Pisum sativum, Vicia faba, Vigna sinensis* or *Wistaria floribunda,* or in the hydrolysate of the protein prepared from seeds of *Stizolobium hassjoo.*

A fuller account of the investigation will be published elsewhere.

Our thanks are due to Dr. E. C. Bate-Smith, of the Low Temperature Research Station, Cambridge, for revising the manuscript.

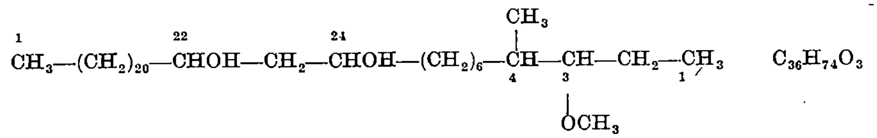
Structure of Phthiocerol

PHTHIOCEROL, a characteristic constituent of the waxes of human and bovine strains of tubercle bacilli[1–3], was found by Stodola and Anderson[1] in 1936 to be a methoxy-glycol with the formula $C_{34}H_{67}(OH)_2OCH_3$ or $C_{35}H_{69}(OH)_2OCH_3$. About ten years ago it was shown that phthiocerol has a long-chain structure with a methyl branch in position 4[4–6]. More recently the presence of a β-glycol grouping was demonstrated[7,8], and several structural formulæ have been suggested on the basis of degradation experiments (for a review see ref. 9). Definite evidence that the methoxyl group is attached to carbon atom 3 adjacent to the methyl group was first obtained by a mass spectrometric study of phthiocerol[10,11], and this was afterwards confirmed by chemical studies[12–14]. The mass-spectrometric results also indicated the presence of a hydroxyl group in position 22 from the straight-chain end of the molecule. The mass spectrum of a purified sample of phthiocerane, the hydrocarbon obtained by reduction of phthiocerol[15], showed this compound to consist mainly of 4-methyltetratriacontane[11]. Structure (I) for phthiocerol was suggested on the basis of the mass spectrometric study[11].

However, oxidative degradation of phthiocerol was found to give two acids, considered to be *n*-tetracosanoic acid[7,16] and a C_{11}-methoxy-acid respectively[16,17]. These results, together with the previously available evidence, led Drayson *et al.*[14] to put forward formula (II) for phthiocerol. Previously one of us (H. D-G.)[12] had suggested that phthiocerol was a mixture of (I) and (II).

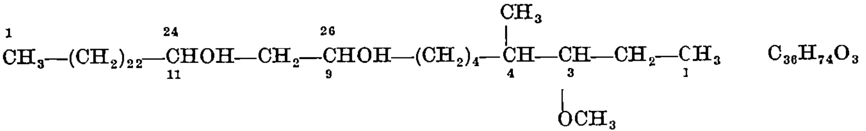
Formula (II) takes no account of the fact that the 'tetracosanoic acid' obtained by chromic acid oxidation of phthiocerol following the procedure of Polgar *et al.* has been shown[11] to be a mixture of the normal chain carboxylic acids with 24, 23, 22 and 21 carbon atoms. The molar relations between these acids were 51 : 9 : 38 : 2. As it seems unlikely that the C_{22} and C_{21} acids have been formed by secondary processes from the C_{24} acid initially formed, the results appear explainable only on the assumption that phthiocerol from natural sources is a mixture of two glycols. One of these glycols must have the first hydroxyl group in position 22 from the straight-chain end and the other the same group in position 24.

In order to clear up this matter, the products of the oxidative degradation of phthiocerol have been examined in some detail. The acidic products formed on oxidation using the procedure described by Drayson *et al.*[14] were converted into methyl esters by means of diazomethane and analysed by gas chromatography and mass spectrometry. The methyl ester of the 'tetracosanoic acid' fraction from a specimen of phthiocerol obtained from Dr. Polgar was found



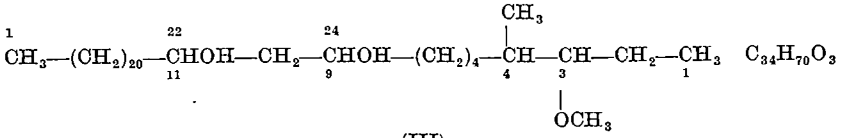
$$\overset{1}{\mathrm{CH_3}}\text{—}(\mathrm{CH_2})_{20}\text{—}\overset{22}{\mathrm{CHOH}}\text{—}\mathrm{CH_2}\text{—}\overset{24}{\mathrm{CHOH}}\text{—}(\mathrm{CH_2})_6\text{—}\underset{4}{\overset{\mathrm{CH_3}}{\mathrm{CH}}}\text{—}\underset{\mathrm{OCH_3}}{\underset{3}{\mathrm{CH}}}\text{—}\mathrm{CH_2}\text{—}\underset{1}{\mathrm{CH_3}}\qquad \mathrm{C_{36}H_{74}O_3}$$

(I)



$$\overset{1}{\mathrm{CH_3}}\text{—}(\mathrm{CH_2})_{22}\text{—}\underset{11}{\overset{24}{\mathrm{CHOH}}}\text{—}\mathrm{CH_2}\text{—}\underset{9}{\overset{26}{\mathrm{CHOH}}}\text{—}(\mathrm{CH_2})_4\text{—}\underset{4}{\overset{\mathrm{CH_3}}{\mathrm{CH}}}\text{—}\underset{\mathrm{OCH_3}}{\underset{3}{\mathrm{CH}}}\text{—}\mathrm{CH_2}\text{—}\underset{1}{\mathrm{CH_3}}\qquad \mathrm{C_{36}H_{74}O_3}$$

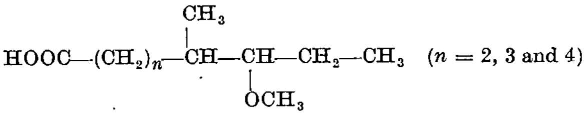
(II)



$$\overset{1}{\mathrm{CH_3}}\text{—}(\mathrm{CH_2})_{20}\text{—}\underset{11}{\overset{22}{\mathrm{CHOH}}}\text{—}\mathrm{CH_2}\text{—}\underset{9}{\overset{24}{\mathrm{CHOH}}}\text{—}(\mathrm{CH_2})_4\text{—}\underset{4}{\overset{\mathrm{CH_3}}{\mathrm{CH}}}\text{—}\underset{\mathrm{OCH_3}}{\underset{3}{\mathrm{CH}}}\text{—}\mathrm{CH_2}\text{—}\underset{1}{\mathrm{CH_3}}\qquad \mathrm{C_{34}H_{70}O_3}$$

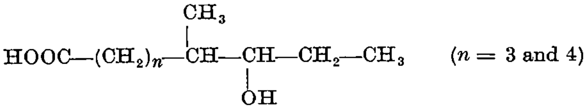
(III)

to consist of a mixture of the methyl esters of the C_{24} to C_{20} acids in the ratios 42 : 18 : 28 : 10 : 1, when subjected to gas chromatography at a temperature of 245° using silicone as stationary phase. Gas chromatography of the 'C_{11}-methoxy'-fraction on 'Apiezon *L*' at a temperature of 199° gave five fractions, which on mass spectrometric analysis were found to be methyl esters of three methoxy-acids:



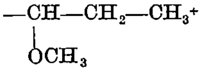
$$\mathrm{HOOC}\text{—}(\mathrm{CH_2})_n\text{—}\overset{\mathrm{CH_3}}{\mathrm{CH}}\text{—}\underset{\mathrm{OCH_3}}{\mathrm{CH}}\text{—}\mathrm{CH_2}\text{—}\mathrm{CH_3}\quad (n = 2,\ 3 \text{ and } 4)$$

and two hydroxy-acids:



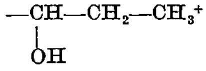
$$\mathrm{HOOC}\text{—}(\mathrm{CH_2})_n\text{—}\overset{\mathrm{CH_3}}{\mathrm{CH}}\text{—}\underset{\mathrm{OH}}{\mathrm{CH}}\text{—}\mathrm{CH_2}\text{—}\mathrm{CH_3}\quad (n = 3 \text{ and } 4)$$

The mass spectra provide highly specific information in this case. The methoxy-esters give an intense peak at $m/e = 73$, which is also found for phthiocerol[11]. This peak is due to the ionized fragment:



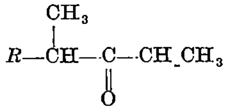
$$\text{—}\underset{\mathrm{OCH_3}}{\mathrm{CH}}\text{—}\mathrm{CH_2}\text{—}\mathrm{CH_3}^+$$

formed by cleavage of the chain between the carbon atoms carrying the methyl and the methoxyl group respectively. The hydroxy-esters just referred to, as well as the triol[7] obtained by demethylation of phthiocerol, give the analogous ion:



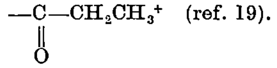
$$\text{—}\underset{\mathrm{OH}}{\mathrm{CH}}\text{—}\mathrm{CH_2}\text{—}\mathrm{CH_3}^+$$

of $m/e = 59$ (ref. 19), whereas oxo-compounds of the general structure:



$$R\text{—}\overset{\mathrm{CH_3}}{\mathrm{CH}}\text{—}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\text{—}\mathrm{CH_2CH_3}$$

give a corresponding large peak at $m/e = 57$ due to the ion:



$$\text{—}\underset{\mathrm{O}}{\underset{\|}{\mathrm{C}}}\text{—}\mathrm{CH_2CH_3}^+\quad \text{(ref. 19).}$$

Quantitatively, the largest components of the 'C_{11}-methoxy'-fraction were the methyl ester of the C_{11}-methoxy-acid (about two-thirds of the total) and the methyl ester of the C_{10}-methoxy-acid, confirming the conclusions of Drayson *et al.*[14] that phthiocerol has a hydroxyl group in position 9 from the branched chain end. The ratio between the C_{11} and the C_{10}-methoxy-acids was about the same (3 : 1) as between the $C_{24} : C_{23}$ and $C_{22} : C_{21}$ pairs of acids respectively derived from the other end of the molecule. This evidence is in agreement with the view that phthiocerol is a mixture of two glycols. The compound might be either a mixture of two homologous β-glycols or a mixture of a β- and a δ-glycol[9,12].

In order to distinguish between these two possibilities, we have examined a specimen of phthiocerane[15] which we had prepared without recourse to purification by repeated crystallization from solvents. Gas chromatography on silicone at a temperature of 265° afforded a clean separation of this material into two fractions, the retention times being 13·8 and 22·2 min. respectively. A specimen of synthetic 4-methyltetratriacontane was found to have a retention time of 22·3 min. under the same conditions, and mass spectrometric examination of the isolated fractions from phthiocerane showed them to consist of 4-methyldotriacontane ($C_{33}H_{68}$) and 4-methyltetratriacontane ($C_{35}H_{72}$) respectively.

The results now reported show that phthiocerol is a mixture of two homologous β-glycols (II) and (III) with 36 and 34 carbon atoms respectively.

The quantitative relation between the C_{35} and the C_{33} components of phthiocerane (from B.C.G.) were approximately the same (3 : 2) as the ratio between the C_{24} and the C_{22} acids obtained by oxidation of a specimen of phthiocerol derived from virulent strains. As the specimens of phthiocerol had all been purified by crystallization from solvents, it seems likely that the homologues (II) and (III) are present in about equal proportions in the bacterial lipids.

The possibility that phthiocerane was a mixture of 4-methyldotriacontane and 4-methyltetratriacontane was suggested previously[5], but considered unlikely at that time because of the reported failure to separate phthiocerane into components by molecular distillation[15].

We are indebted to Prof. R. J. Anderson, Yale University, for specimens of phthiocerol and phthiocerane, and to Dr. N. Polgar, Oxford, for specimens of phthiocerol and of C_{11}-methoxy-acids.

We also thank the Fondation Waksman pour le Développement des Recherches microbiologiques en France and the Swedish Medical Research Council for several grants, and Drs. J. Tréfouël and J. Bretey

(Institut Pasteur, Paris) for a large number of bacterial cultures.

Changes produced in Serum Lipoproteins of Dogs by Cellulose containing Methyl Groups

It has been observed by several authors that macromolecular polysaccharides, especially those containing sulphate groups, cause significant alterations in the lipoprotein patterns of sera[1,2]. In the course of previous studies on the effect of methylcellulose on blood-proteins[3] certain changes in serum lipids were also noted. So it seemed to be of interest to examine what influence methylcellulose of high molecular weight (82,000) exerts *in vitro* as well as *in vivo* on the lipoproteins of sera of experimental animals.

Paper electrophoretic patterns of the lipoproteins in dog and rat sera were obtained after adding solutions of methylcellulose (in concentrations varying progressively from 1·5 to 0·1 per cent). Fig. 1 shows that the presence of methylcellulose considerably alters the chylomicrons but no change can be seen in the α- and β-lipoprotein fractions. The extent of the chylomicron zone is about the half that on the control strip and it is characterized by a sharp peak towards the line of application. The intensity of this peak tends to increase with the concentration of methylcellulose in the serum. Just the same change appeared in the lipoprotein pattern of sera of dogs 30–60 min. after they had received an intravenous injection of a 1 per cent solution of methylcellulose, but disappeared again in a short time. If a solution of methylcellulose was layered over lipæmic sera in capillary tubes, a loose aggregate was formed which later moved slowly upward, while the opalescence of the serum below the interface cleared up. These results suggest that methylcellulose is capable of exerting considerable influence on the large lipid particles of sera.

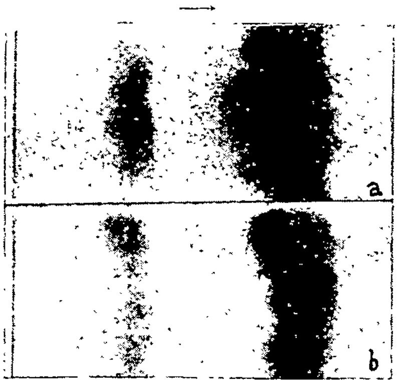

Fig. 1. (*a*) Lipoprotein electrophoretogram of normal dog serum; (*b*) the same serum after the addition of methylcellulose solution

The lipoprotein pattern of dogs treated with 20 ml. of a 1 per cent solution of methylcellulose administered intravenously twice weekly for 3–5 months is presented in Fig. 2. The remarkable increase of a component between the alpha and beta peaks—faintly visible in some of the normal cases—can be observed on the electrophoretogram of dogs treated with methylcellulose. Furthermore, a significant rise in the cholesterol-level was also found after long-term treatment, its mean value being 340 mgm. per cent in treated and 222 mgm. per cent in untreated animals, respectively. Thus long-term administration of methylcellulose alters not only the electrophoretic pattern of lipoproteins but the cholesterol content of blood as well.

Results obtained by paper-electrophoresis with rats injected intraperitoneally with methylcellulose, as well as those described above, do not show any similarity to the heparin-like effect of cellulose sulphate described by Constantinides[1]. It seems therefore that the substituent groups are an important factor in the mode of action of macromolecular polysaccharides on the lipoproteins. Not only the character of the changes caused but also the

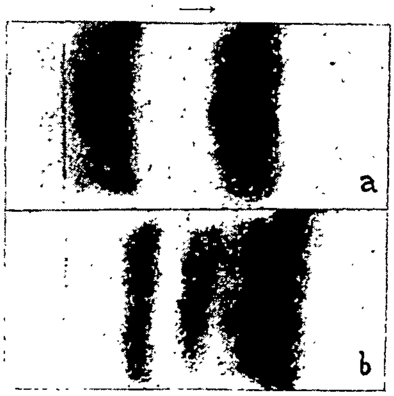

Fig. 2. Lipoprotein electrophoretogram of dog serum, (*a*) before, and (*b*) after, methylcellulose treatment

time needed for their establishment depends on the substituents.

Histological examination of six dogs after long-term treatment showed infiltrations mostly containing mononuclear cells in the wall of the small arteries, perivasculitis, a considerable intima proliferation and formation of granuloma in the interstitium of the lung tissue. This histological picture resembles that of thromboembolic arteriitis.

Further experiments are in progress in order to elucidate the mode of action of methylcellulose on the lipoproteins, as well as the relation between the lipoprotein disturbances and the histological picture.

Gas-Chromatographic Observation of the Reduction of Carbon Dioxide to Methane during Anaerobic Digestion

Gas chromatography has been applied to the analysis of gases formed during methane fermentations[1]. It appeared to us that this technique could be used successfully for observing the mechanism of methane formation. Knowledge of the biochemistry of methane-producing bacteria is still superficial in many respects. Early observations of Söhngen[2] showed the possibility of the fermentation of a mixture of carbon dioxide and hydrogen by enrichment cultures of some anaerobic bacteria. These micro-organisms could couple the oxidation of hydrogen with the reduction of carbon dioxide to methane. More recently, Barker[3] had discussed the mechanisms by which carbon dioxide could be the precursor of methane.

In this laboratory a method of analysis of fermentation gases was applied using gas chromatography to separate various components of the gas mixture by argon elution from an absorption column packed with activated carbon. The detection of these components was achieved by a beta-radiation ionization chamber (ref. 4 and personal communication from A. T. James). A method based on this principle allowed the determination during a single analytical procedure of hydrogen, nitrogen, methane and carbon dioxide.

The gas-chromatography apparatus consisted of the sample-injection system, manometer, chromatographic column in an electrically heated jacket, beta-radiation detector, soap-film flowmeter and carrier-argon supply cylinder. The source of β-rays for the ionization chamber detector was 10 mc. of strontium-90 in silver foil in the shape of an open cylinder, which was mechanically and electrically joined to the body of the chamber. The chamber itself was constructed of brass and a 'Champion' *C*–5 sparking plug, modified by the addition of a brass cap, was used as the central collecting electrode, with the radioactive cylinder surrounding it. The gas inside the cell of the detector was bombarded with β-particles and was ionized. When the walls of the chamber (and the radioactive electrode) were connected to a source of 300 V. from a voltage stabilizer, the ionization current collected by the central electrode was amplified and recorded by a Honeywell–

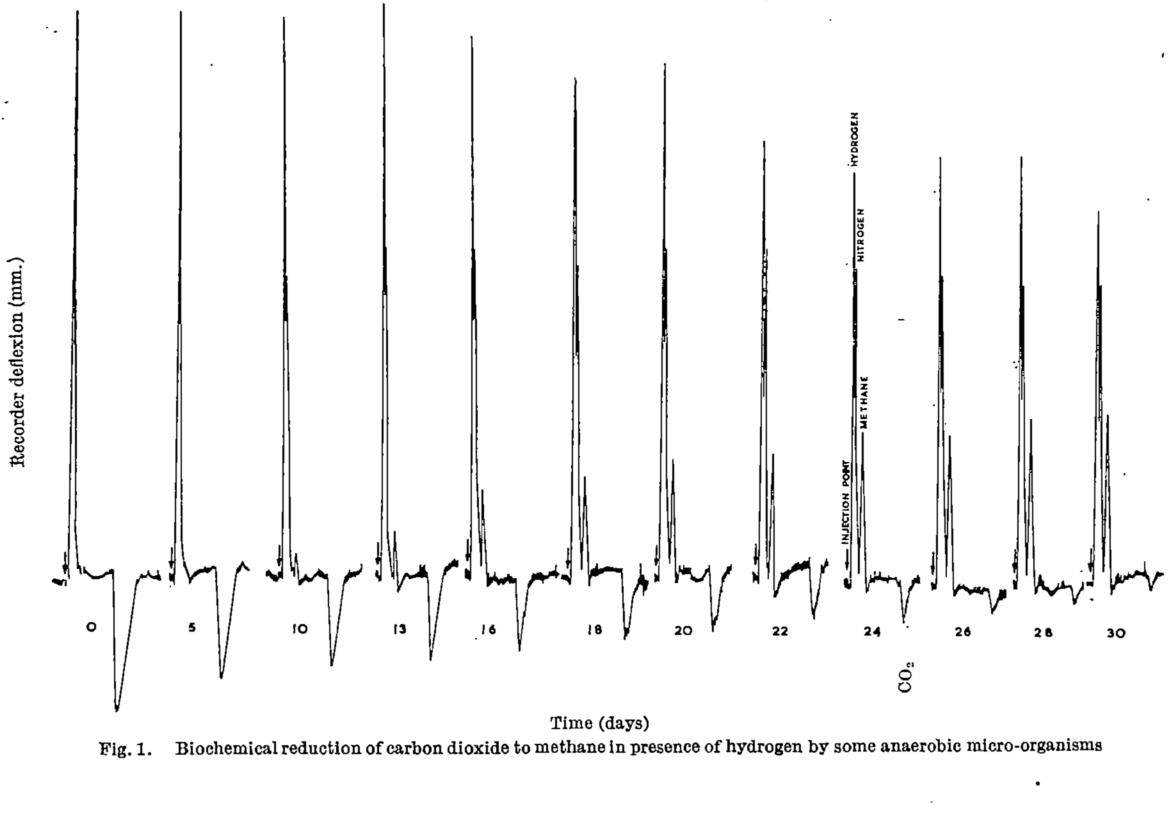

Fig. 1. Biochemical reduction of carbon dioxide to methane in presence of hydrogen by some anaerobic micro-organisms

Brown potentiometric recorder. The amplifier was adjusted so that the recorder indicated the chosen base-line for the constant flow of pure argon, and gave a deflexion for argon carrying other gases. The gaseous constituents separated by the chromatographic column were detected and recorded as more or less separate peaks on the time-deflexion graphs of the recorder. Relationships between peak height and volume of gas sample for hydrogen, nitrogen, methane and carbon dioxide were established and used as calibration curves for the determination of the gases resulting from the anaerobic processes. Higher sensitivity of the ionization detector for hydrogen and nitrogen than for carbon compounds was observed in this investigation. All the determinations were performed under standardized conditions as indicated in the next paragraph.

The chromatographic column used was a glass tube, of approximately 4 mm. diameter and 4 ft. long, packed with about 6·5 gm. of activated carbon (Sutcliffe, Speakman No. *B*–206) ground to 30–70 mesh. Both the chromatographic column and the ionization chamber were enclosed in a heating jacket with temperature-control equipment which maintained the temperature at 50 ± 0·5° C. to ensure the stability of the chromatographic sorption processes. The rate of flow of the carrier argon has been fixed at 46 ml./min., which required an input pressure of 230 mm. mercury. Samples of 5 or 10 ml. of gas under investigation were measured under atmospheric pressure by hypodermic syringe and were introduced to the flow of carrier argon through a rubber serum cap on the top of the column.

Some preliminary observations have been made of the biochemical reduction of carbon dioxide to methane during anaerobic fermentation. Volumes of 2·5 l. of fully digested sewage sludge were placed in 10-l. reacting bottles supported with their axes horizontal on rubber-covered rollers. These reactors were fitted with 'Perspex' stationary stirrers and continuously rotated at about 7 rev./min. A rubber cap, acting as a valve, allowed gas exchanges, pressure measurements and the withdrawal of gas samples using hypodermic needles. The reactors were installed in a room in which the temperature was maintained at 32–33° C. with the aid of a thermostatically controlled heater and fan. Digested sludge was gassed by a mixture containing approximately 50 per cent carbon dioxide (by volume) and about 35 per cent hydrogen. A 15 per cent concentration of nitrogen was also present as an indicator since it took no part in the reaction. At the start the total gas pressure was about 30 mm. mercury above atmospheric. Biochemical hydrogen uptake diminished this pressure at the rate of 50–70 mm. mercury per day, which was dependent on the stage of the fermentation process. When necessary, every two or three days, the pressure in the reactor was restored by introduction of a further volume of hydrogen to give an approximately constant concentration of this gas in the digester. At this stage a sample of the gas was taken for gas-chromatographic investigation.

Fig. 1, which represents a series of such observations, shows that during 30 days of operation carbon dioxide concentration in the gas mixture fell from 50 per cent to about 0·5 per cent. It will be noticed that at about the tenth day methane was present in the reacting gas and that the methane steadily replaced carbon dioxide, increasing to about 50 per cent in the gas mixture.

This dynamic observation suggested the desirability of carrying out gas-chromatographic trials on the kinetics of hydrogen uptake by methane bacteria. At the conclusion of the normal methane fermentation, digested sludge was in contact with fermentation gas composed of approximately 65 per cent methane, 35 per cent carbon dioxide and traces of nitrogen. The addition of about 15 per cent of hydrogen enabled the uptake of hydrogen from this change to be observed by gas chromatography for 90 hr., after which there were no further traces of this gas.

These preliminary observations demonstrate the usefulness of the gas-chromatographic technique for such investigations. It is clear that more detailed studies, including a materials balance, are required for a full elucidation of the kinetics of these reactions.

'Vapour Toxicity' of Solid Insecticides

When considering the performance of solid insecticides of the chlorinated hydrocarbon type, such as DDT, γ-BHC and dieldrin, a factor frequently considered is the toxic properties of the vapours from crystalline deposits. To assess this factor biologically, both in the laboratory and in the field, the commonest practice is to keep cages holding test insects a short distance from the treated surface. The toxic effect found after such an exposure is generally referred to as the 'vapour toxicity'.

However, calculation of the concentration of the saturated vapours of the insecticides mentioned above made it seem very unlikely, particularly in the cases of dieldrin and DDT, that such concentrations are high enough to cause a noticeable mortality, even of susceptible insects exposed for 24 hr. Using the equation:

$$C = (p/PV_0)M$$

in which p is the vapour pressure of the insecticide in mm. mercury, P is atmospheric pressure in mm. mercury, V_0 (the volume of ideal gas) = 22·4 l. atm. mole^{-1}, M is the molecular weight and C the concentration of the saturated vapour in grams per litre, one obtains concentration figures of 0·004, 0·53 and 0·004 μgm./l. for dieldrin, γ-BHC and *pp*-DDT respectively, the calculations being based on the results collected in Table 1. As the *LD*95 for *Drosophila melanogaster* Meig. and *Aedes aegypti* L. is of the order of 0·005 μgm./insect with dieldrin and γ-BHC,

Table 1. Vapour Pressures in mm. of Mercury

Insecticide	Vapour pressure	Temperature	Reference
Dieldrin	$1{\cdot}8 \times 10^{-7}$	25° C.	1
pp-DDT	$1{\cdot}5 \times 10^{-6}$	20° C.	2
γ-BHC	$3{\cdot}0 \times 10^{-5}$	20° C.	3

and 0·05 μgm./insect with DDT, it is not surprising that air virtually saturated with vapours of any of these three insecticides proved to be non-toxic to those insects.

The experiment was arranged as follows: Air was passed through two U-tubes filled with powdered insecticide at a rate of approximately 20 l. in 24 hr. On leaving the first tube, which was kept at a temperature of approximately 80° C., the air would be nearly saturated with insecticide at that temperature; in the second, held at about 18–20° C., the excess insecticide would recondense, leaving the air just saturated at that lower temperature. The vapour was then led through a container held at a temperature of 23–24° C., holding *Drosophila melanogaster* and *Aedes aegypti*. At this temperature the vapour is thus just not saturated. No deaths were observed among insects exposed in this way for 24 hr.

Further investigations have shown that the toxic effect often observed in experiments estimating vapour toxicity is mainly caused by insecticide acquired by the insects in an indirect way, namely, via a condensed film formed on the body of the holding cage. It is thought that appreciable condensation will take place only in a system containing saturated vapour and not in the system described above. The following experiments demonstrate the condensation phenomenon in systems with saturated vapours.

Some 10 mgm. of crystalline insecticide was evenly distributed over the bottom of a Petri dish from a solution in hexane. After evaporation of the solvent, this dish was covered by a sheet of filter paper which was larger than the rim of the dish, and covered by a second, untreated dish placed upside down on the filter paper. Care was taken that neither the filter paper nor the top dish was contaminated during this procedure. Remaining in this position overnight, the filter paper and the top dish were then separated from the dish holding the insecticide. *Drosophila melanogaster* were then exposed to the filter paper (both sides) and the top dish, the result being complete kills in all cases. Exposing metal, plastic and muslin fabric in a similar way also gave high kills of *Drosophila melanogaster* exposed to the condensed films.

The actual amounts condensed on the glass were estimated as follows: the top dishes of the combinations just mentioned (without filter paper this time) were exposed over-night to vapours from the insecticide in the bottom dish. The top dish was then removed and the condensed insecticide dissolved in hexane and dilutions of it applied on to the bottom of clean Petri dishes. Houseflies (*Musca domestica* L.) were exposed to the dry residue and the results compared with those obtained simultaneously with known amounts of insecticide. In this way the condensates of dieldrin were found to amount to a little more than 1 μgm./dm.^{2}; the condensates of DDT and γ-BHC were of the order of a few μgm./dm.^{2}. The condensates actually found on an area of 1 dm.^{2} contained, except in the case of DDT, sufficient insecticide to give a complete kill of 20 female houseflies exposed for 24 hr. With more susceptible insects such as *Drosophila melanogaster* and *Aedes aegypti*, complete mortality was also obtained with DDT.

It can be concluded from this that, in closed systems, the vapours of DDT, γ-BHC and dieldrin may condense on various materials in concentrations of a few μgm./dm.^{2}; this is sufficient to kill susceptible insects. The consequence is that where cases in the literature in general do refer to the 'vapour effect', in fact the effect is of such surface deposits of condensed vapour plus the effect of an eventual condensate directly on the insect.

It need not be stressed that this condensation can be influenced by a great number of variables, and thus that the results provided are of highly questionable value.

Moisture Content of Whole Bread and Bread Crumb

In order to secure that bread is properly baked, the statutory regulations and laws prescribe maximum permissible moisture content of the baked product. In some countries the law is based on the water content of the whole loaf; in others the maximum permissible moisture content of the crumb only is laid down.

In order to compare the value of these methods in judging proper bread baking, the following sets of experiments were made (in each case with both white and high-extraction flour).

(*A*) Three pieces from one dough were scaled at 580 gm. each, fermented, panned and baked to variable final weight; (*B*) three doughs of various consistencies, and water contents, were scaled at 580 gm. and baked to a weight of 500 gm. in each case.

In all loaves the moisture content of the whole loaf and of the crumb only was determined.

Table 1. Moisture Content of Bread and Bread Crumb

No.*		Weight of baked bread (gm.)	Moisture of crumb (per cent)	Moisture of whole bread (per cent)
A	1	520	45·6	40·8
	2	500	45·4	38·4
	3	481	44·8	36·2
	4	520	45·8	41·0
	5	500	45·8	39·1
	6	480	45·9	36·0
B	7	500	46·1	39·5
	8	500	45·1	37·9
	9	500	44·6	37·6
	10	500	46·2	39·8
	11	500	45·9	37·8
	12	500	44·8	37·3

* 1–3, 7–9, dark wheat bread; 4–6, 10–12, white bread.

The results (Table 1) seem to show that prolonged baking has little, if any, influence on moisture content of the crumb, and that the latter is rather a measure of water content of dough from which the bread was baked than a criterion of adequate baking and proper crust formation.

PHYSIOLOGY

Excretion of Catechol in Human Urine

During a study of the catechol compounds in human urine it was observed that acid hydrolysis (20 min., 1 *N* sulphuric acid, 100° C.) caused a large increase in the content of some catechol compounds, presumably by splitting of a conjugate[1]. Chromatographic separation of the different catechols obtained by adsorption on alumina of hydrolysed urine indicated that the large increase was connected with a catechol compound having a rate of flow similar to that of 3,4-dihydroxyphenyl acetic acid in a solvent system of *n*-butanol–hydrochloric acid–acetic acid[2].

Further analysis of the chromatographically separated fractions revealed that the catechol compound differed from 3,4-dihydroxyphenyl acetic acid in its migration pattern in different systems. From its position on paper when butanol–hydrochloric acid and *m*-cresol–acetic acid–water[3] were used as solvents, and by the colour observed on spraying with ferricyanide or ferric chloride, the compound was identified as catechol itself, Fig. 1. This conclusion was further corroborated by colour reactions in solution after addition of ferric chloride, by separation with ion-exchange resins and by fluorescence curves in the spectrophotofluorimeter.

The appearance in urine of a conjugate with sulphuric acid after ingestion of catechol in dogs was shown by Baumann[4] who also claimed that human urine may contain this compound. More recently, Fiker[5] has reported that hydrolysed normal urine contained 5 mgm. catechol per litre.

The amounts of catechol found in five samples of normal human urine after acid hydrolysis varied between 46 and 108 μgm./hr., and was on an average 82 μgm./hr.

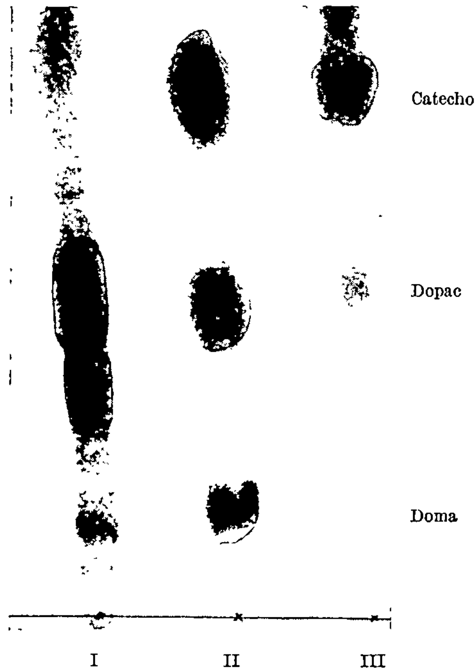

Fig. 1. Paper chromatogram, Whatman No. 1, *m*-cresol–acetic acid–water. (I) Fractions 8·8–13·2 ml. from column chromatogram of unhydrolysed normal human urine, adsorbed on alumina, solvent *n*-butanol–hydrochloric acid–acetic acid–water; (II) standards, catechol, dopac (3,4-dihydroxyphenylacetic acid); doma (3,4-dihydroxymandelic acid); (III) same as I but urine treated with 1 *N* sulphuric acid, 20 min., 100° C. before adsorption. In III about one-fifth of amount of urine in I

No evidence for the presence of catechol in unhydrolysed human urine was obtained. Catechol was also found in cow's urine after hydrolysis.

The origin and formation of the catechol are at present being studied.

Mechanism of Action of Insulin

Experiments have been carried out to determine to what extent insulin lowers the glucose concentration in the plasma by increasing glucose utilization by the tissues and to what extent by diminishing glucose production by the liver.

Trained dogs were used in the post-absorptive state and without anæsthesia. The size of the body glucose pool and the rates of glucose production and utilization in the resting state and during periods of changing blood glucose concentrations were determined by the use of an isotope dilution technique using ^{14}C-glucose[1-3]. The body glucose pool was labelled by a priming injection of a trace amount of uniformly labelled ^{14}C-glucose. The established specific activity was maintained for several hours by a constant infusion of a trace amount of glucose labelled with carbon-14 which balanced the endogenous ^{12}C-glucose output by the liver, provided this output remained constant[1]. After the radioactive glucose had been infused for 2 hr., trypsin-treated crystalline insulin (low in glucagon content; Lilly) was administered in one of the following ways, while the labelled glucose infusion continued uninterrupted: (*a*) single intravenous injection; (*b*) continuous intravenous infusion; (*c*) subcutaneous injection. Samples of blood were collected at intervals and the plasma glucose concentration and specific activity were determined. From these results the glucose production and utilization were calculated[1,3].

It was previously shown[3] by use of this technique that when insulin is administered as a single intravenous injection the resulting hypoglycæmia is due mainly to an increased uptake of glucose by the tissues. The initial transient diminution of glucose release from the liver which was often observed was a relatively minor factor in the development of the hypoglycæmia. The return of the glucose concentration in the plasma to the control value was found to be brought about by a sudden increase in the release of glucose from the liver in response to the hypoglycæmia.

In the present studies insulin was introduced into the jugular vein through a polyethylene tube by means of a constant infusion pump. The insulin dosage varied from 0·1 to 0·25 U./kgm., infused in 90 min. In each case a hypoglycæmia developed which persisted throughout the period of insulin infusion. As shown by the relatively unchanging level of specific activity of plasma glucose the hypoglycæmia was due almost entirely to increased utilization of glucose, the glucose production remaining at about the pre-insulin level. Cessation of glucose production was never observed.

In order to determine whether physiologically secreted endogenous insulin lowers the blood sugar by the same mechanism as exogenous insulin, the secretion of insulin by islet tissue was provoked by the administration of a glucose load. The experiments were designed to provide a more adequate test than similar experiments which were reported recently[4] in which smaller glucose loads were injected in anæsthetized dogs. The body glucose pool was labelled with ^{14}C-glucose and the specific activity was maintained by a constant infusion of labelled glucose as described above. At 2 hr. a glucose load sufficient to maintain a hyperglycæmia for 45–60 min. was administered. The glucose load had the same specific activity as the glucose already circulating in the plasma. Infusion of the trace amount (less than 2 mgm./hr.) of labelled glucose was continued uninterrupted throughout the experiment. As shown by the unchanging specific activity of plasma glucose, glucose production by the liver continued during hyperglycæmia at the same rate as before the glucose load was given. The rate of glucose utilization during the hyperglycæmia was always greatly increased.

Thus it appears that physiologically secreted insulin, like administered exogenous insulin, lowers the concentration of blood sugar almost entirely by increasing utilization of glucose.

An additional finding, possibly of considerable importance, was made with regard to the restoration of the level of blood sugar after insulin-induced hypoglycæmia. The restoration of the level of blood sugar to normal, following a single intravenous injection of insulin, begins at about the lowest point of the glucose concentration curve, at which time a marked increase in glucose production occurs rather suddenly[3]. In the case of the experiments involving prolonged (90 min.) insulin infusions, this extra glucose output in response to hypoglycæmia occurred only after termination of insulin infusion, whereupon again it occurred rather suddenly and restored the blood sugar to normal.

Thus although insulin brings about hypoglycæmia primarily by increasing uptake of glucose and not by decreasing hepatic glucose output, the presence of newly injected exogenous insulin affects the animal in such a way that it fails to increase its hepatic glucose output in response to hypoglycæmia.

Action of Pyrrolizidine Alkaloids on the Neuro-Muscular Junction

Median lethal doses of the plant pyrrolizidine alkaloids, heliotrine and lasiocarpine, have been determined by Bull *et al.*[1]. Deaths occurred from hepatotoxic effects except in some female rats given heliotrine.

The present study showed that injection of larger doses than the *LD*50 of the alkaloids, but not of their N-oxides, produced progressive muscular weakness, respiratory distress and death from respiratory failure within 30 min., suggesting the occurrence of a neuro-muscular block.

Rat phrenic nerve-diaphragm preparations were made by the method of Mogey *et al.*[2]. N-oxides of the alkaloids did not affect transmission of impulses or contraction in such preparations. However, small doses, 1–6 μM/ml., of heliotrine or of lasiocarpine first potentiated then blocked the diaphragmatic response to phrenic nerve stimulation. The lowest effective doses increased the amplitude of the contractions. With slightly higher concentrations, the initial increase in amplitude was followed by partial but progressive inhibition of contraction. Larger doses immediately inhibited contraction and rapidly led to complete inhibition. Lasiocarpine was effective in lower concentrations than heliotrine.

During complete block, the muscle responded normally to direct stimulation. Also the addition of these alkaloids to the nerve bath only, did not affect impulse transmission. The effect of the alkaloids is thus localized at the neuro-muscular junction. The block was reversed by washing the preparation free of alkaloid. However, despite the apparent complete reversal, subsequent doses of either alkaloid were potentiated. Neither prostigmin nor pentamethonium influenced inhibition due to the alkaloid or the rate of recovery from it.

The procedure outlined by Paton and Zaimis[3] was used for recording contractions of the anterior tibial muscle of cats upon stimulation of the sciatic nerve. Lasiocarpine (5–250 μM), injected into the femoral vein had no obvious immediate effect on contraction but the twitch amplitude slowly decreased. Injection of 5 and 10 μM into the isolateral anterior tibial artery increased at once the amplitude of contraction which then slowly decreased. Immediate and progressive inhibition resulted from 20 μM lasiocarpine injected intra-arterially.

The development of inhibition was not influenced by 3 mgm. potassium chloride or 0·5 mgm. pentamethonium. However, 0·25 mgm. prostigmin increased the degree of inhibition immediately. Intra-arterial injection of 25 μgm. *d*-tubocurarine produced an almost complete block of contraction which was promptly reversed by 1 mgm. prostigmin. However, the partial block produced by 15 μgm. curare did not prevent the inhibitory effect of 20 μM lasiocarpine nor was the resultant complete inhibition antagonized at all by 1 mgm. prostigmin. Tetany did not remove lasiocarpine inhibition, and contraction during tetany seemed well sustained compared with curarized muscle.

The alkaloids did not inhibit cholinesterase or the activation of acetate. The possibility of an effect on the succeeding step of acetylcholine synthesis will be investigated.

Present knowledge seems inadequate to separate agents which block impulse transmission at neuro-muscular junctions into discrete groups. With reference to the differences drawn between decamethonium-like (C_{10}-like) and *d*-tubocurarine-like compounds by Paton and Zaimis[3], the pyrrolizidine alkaloids have resemblances to, and differences from, both groups. They resemble C_{10} in the enhancement of muscle contraction in low concentrations, the failure of inhibited preparations to respond to potassium chloride, the increased inhibition resulting from prostigmin administration, the relatively well sustained contraction during tetany and failure to recover from inhibition after tetany; but they differ in the inability of the prior injection of curare to antagonize alkaloid inhibition and the failure of pentamethonium to reverse the inhibition.

Hæmoglobin of New-born Infants in Indonesia

Studies on the hæmoglobin of new-born infants, including electrophoretic examinations, have been carried out by several workers. Normally, the red blood cells of new-born infants contain two types of hæmoglobin, fœtal hæmoglobin (Hb *F*) and normal hæmoglobin (Hb *A*). The fœtal hæmoglobin, which is resistant to alkali and has a different electrophoretic behaviour from that of normal adults, is the major component. The amount of hæmoglobin *F* in cord blood ranges from 50 to 90 per cent of the total.

In 1957, Fessas and Papaspyrou in Greece found an unusually fast-moving hæmoglobin component in a new-born infant who had symptoms of thalassæmia and whose parents were thalassæmics[1]. Nanakorn, in Thailand, reported a fast-moving hæmoglobin component in the blood of a new-born baby which she thought was hæmoglobin *H*[2]. However, this component has never been compared with the fast-moving hæmoglobin of Fessas and Papaspyrou. Agar and Lehmann reported the finding of a fast-moving hæmoglobin in a new-born baby of Chinese–Negro–Spanish–English origin, which the authors called the 'Bart's' hæmoglobin and which at *p*H 8·6 was slightly faster than that of Fessas and Papaspyrou[3].

I have continued my previous studies on the hæmoglobin of new-born infants[4,5] by making a survey of the hæmoglobin of cord blood of new-born infants in three hospitals in Djakarta. The hæmoglobins prepared from the blood samples were all examined electrophoretically by the paper electrophoretic method of Smith and Conley[6]. In many the amount of hæmoglobin resistant to alkali was estimated by the method of Singer *et al.*[7].

A total of 1,138 samples of blood was examined. 633 samples were from Chinese and Indonesian Chinese, 480 from Indonesians, 22 from Indonesian–Dutch infants, and three of other nationalities. The great majority of the samples contained normal and fœtal hæmoglobin, the alkali-resistant hæmoglobin being the major component. However, in several of the samples, a third component was present. In this material there were two kinds of an unusual third component. The first was a slow-moving hæmoglobin, while the other was a fast-moving one.

The slow-moving component at *p*H 8·6 migrated slightly faster than hæmoglobin *E* on horizontal paper electrophoresis. It was present in small quantities. Among the 633 Chinese infants (Chinese and Indonesian–Chinese), one carried this hæmoglobin in the cord blood, while the blood of 2 out of 480 Indonesian new-born babies were found to contain this component. Of the 17 Indo–European babies, one had this hæmoglobin at birth. In two of the four infants who carried a slow-moving hæmoglobin (one Indonesian and one Indo–European baby), this component was thought to be hæmoglobin *E*, because both parents could be examined and in both one of the parents had hæmoglobin *E*. The slight difference in migration-rate may be due to the relatively small amount of this hæmoglobin present. Previously[5,8] I described the postnatal formation of hæmoglobin *E* in several infants but it was not found at birth. I also noted at that time, that, when the component started to appear in the blood in a very low concentration, it migrated, at *p*H 8·6, slightly faster than hæmoglobin *E*. After some time, when the child was older, the component was present at a higher concentration. It then had exactly the same mobility as the hæmoglobin *E* in the mother. It seems from the findings in this communication that in a small proportion of hæmoglobin *E* trait carriers the hæmoglobin *E* is already detectable at birth. In the other two infants who had a slow-moving component it cannot be said that this was probably *E*, because the parents could not be examined.

The other abnormal third hæmoglobin, which was present in several of the cord-blood samples, was a fast-moving one, at *p*H 8·6 was much faster than hæmoglobin *A*, had about the same mobility as hæmoglobin *J*, but was definitely slower than *H* (Fig. 1). At *p*H 6·5 it was definitely less anodic than hæmoglobin *H*, which migrated clearly to the positive pole (Fig. 2). This hæmoglobin resembled the one

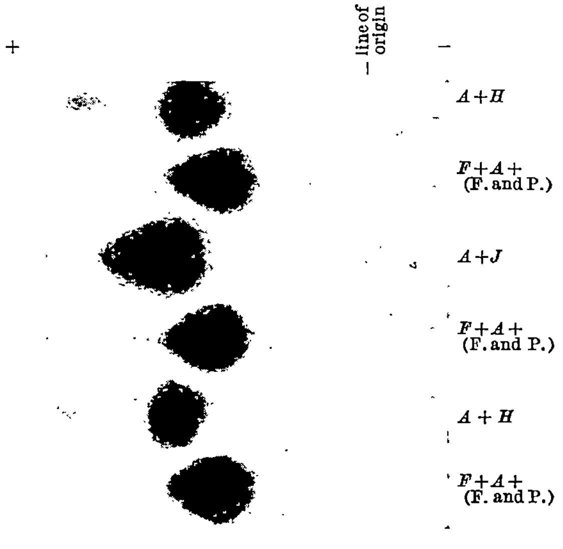

Fig. 1. Paper electrophoresis at *p*H 8·6 of the hæmoglobin of Fessas and Papaspyrou (F. and P.) in new-born babies compared with hæmoglobins *H* and *J*

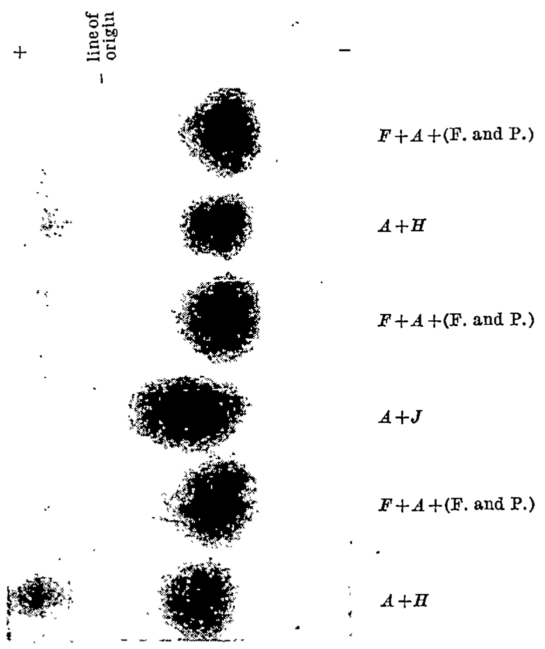

Fig. 2. Paper electrophoresis of the same hæmoglobins as in Fig. 1 at *p*H 6·5

described by Fessas and Papaspyrou in its mobility at acid as well as at alkaline *p*H. I therefore sent a sample to Dr. Fessas, who confirmed our findings and found that it was similar to that described by him and Dr. Papaspyrou. This hæmoglobin is not very stable. When kept in the refrigerator it disappeared after some time, but was more stable when frozen. It did not give rise to intracellular crystal formation in erythrocytes after several hours incubation in brilliant cresyl blue and therefore differed also in this respect from hæmoglobin *H*. A total of 23 samples was found to contain this fast-moving hæmoglobin: 21 in Chinese (among 633 samples) and 2 in Indonesian babies (among 480 samples). The parents of these babies do not have any abnormal hæmoglobin.

It seems that the hæmoglobin of Fessas and Papaspyrou is not very rare in Chinese and Indonesian new-born babies in Indonesia. Vella has found this hæmoglobin in Chinese new-born infants in Singapore[9]. It may be that this hæmoglobin is not rare in new-born infants in the whole of East Asia.

A clinical and hæmatological study was made of the babies carrying this fast-moving component and of their families. In addition, a follow-up study was made of several of the babies. The results of this study will be published separately.

Effect of Toxopyrimidine on Glutamic-decarboxylase and Glutamic-oxalacetic Transaminase of Rat Brain

In a previous communication Rindi and Ferrari[1] reported a statistically significant decrease of γ-aminobutyric acid in the brain of rats treated with a structural pyridoxamine antagonist having an epileptogenic action, namely, 2-methyl,4-amino,5-oxymethylpyrimidine (toxopyrimidine). In this communication we wish to report results obtained in an enzymatic study of the action of toxopyrimidine. We determined the glutamic decarboxylase and glutamic-oxalacetic transaminase (both pyridoxal-phosphate linked enzymes) in the brain of rats with epileptic seizures caused by injection of toxopyrimidine, and of rats restored to normal with pyridoxamine.

The experimental conditions were as previously described[1]. Toxopyrimidine and pyridoxamine were injected intraperitoneally: at doses of 125 μgm./gm. and 62 μgm./gm. respectively.

Glutamic-decarboxylase activity was evaluated[2] by determining by paper chromatography[1] the increase in the formation of γ-aminobutyric acid in brain homogenate after the addition of glutamic acid (Table 1). Glutamic-oxalacetic transaminase was determined by the colorimetric method by Tonhazy, White and Umbreit[3] with minor modifications[4].

Table 1. Glutamic-decarboxylase and Glutamic-Oxalacetic Transaminase Activities of Brain of Rats treated with Toxopyrimidine (Mean ± Standard Error)

4	Treated + vitamin B_6 6 hr. after pyridoxamine	247·5 ± 7·9			

* Reaction mixture, in phosphate buffer 0·05 *M*, *p*H 6·2: (*a*) 2 ml. homogenate containing 250 mgm. of tissue + 0·5 ml. *l*-glutamic acid. 0·62 *M*, *p*H 6·2; (*b*) 2 ml. homogenate + 0·5 ml. phosphate buffer. The increment is calculated by subtracting the γ-aminobutyric acid content in (*b*) from (*a*).

† Q_T^{10}, μl.CO_2/mgm. dry tissue per hour (see ref. 3).

The results summarized in Table 1 show a statistically significant ($t = 3{\cdot}412$; $0{\cdot}01 > P > 0{\cdot}001$) inhibition of glutamic decarboxylase activity in the epileptic brain in comparison with control (and normal) animals.

3½ hr. after the injection of pyridoxamine, which quickly abolished epileptic seizures, the inhibition was completely eliminated. Since the decrease of decarboxylase activity (20·4 per cent) was of the same order[1] as the decrease in cerebral γ-aminobutyric acid (23·3 per cent) after injection of toxopyrimidine, we can assume that the two results are closely related. On the other hand, no modification in cerebral glutamic oxalacetic transaminase activity after administration of toxopyrimidine was apparent. Killam and Bain[5] reported similar results using convulsant hydrazides. They suggested that pyridoxal-phosphate is more firmly bound to the apoenzyme in the transaminase than in the decarboxylase[6,7].

Our results support the views of Tower[8], who recently emphasized the importance of the glutamic acid–γ-aminobutyric acid system in neuronal function, and the close connexion between glutamic decarboxylase inhibition and the onset of epileptic seizures in dietary or antimetabolite pyridoxine deficiency.

Effect of Ouabain on Sodium Flux in Human Red Cells

It has been shown that the cardiac glycosides inhibit the transport of cations in human red cells[1-3], and it appears that this effect is exerted directly on the transport mechanism rather than on its energy supply[3-5]. Though some studies of the effect of these drugs on transport of sodium have been made, interest has been centred on the inhibition of transport of potassium. The present communication is concerned with the relationship between the sodium and potassium fluxes in human red cells treated with the cardiac glycoside, ouabain.

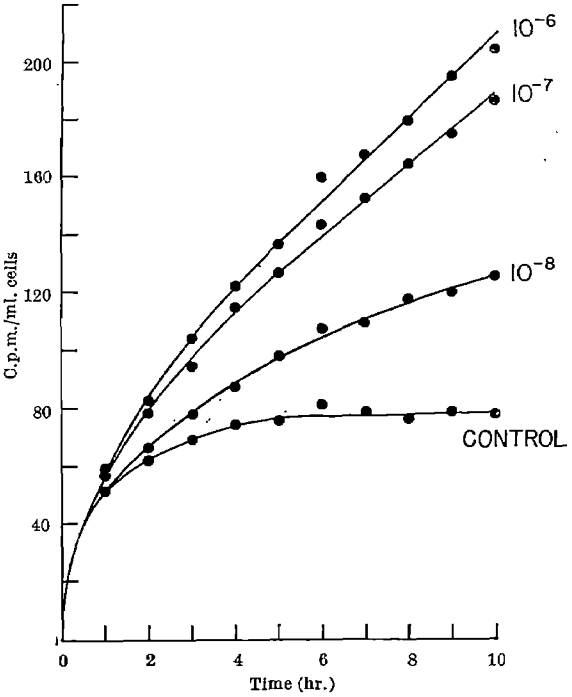

Fig. 1. Typical influx experiment showing the effect of ouabain on accumulation of sodium. Sodium chloride labelled with sodium-24 was added to fresh, heparinized human blood (relative cell volume, approximately 45 per cent)

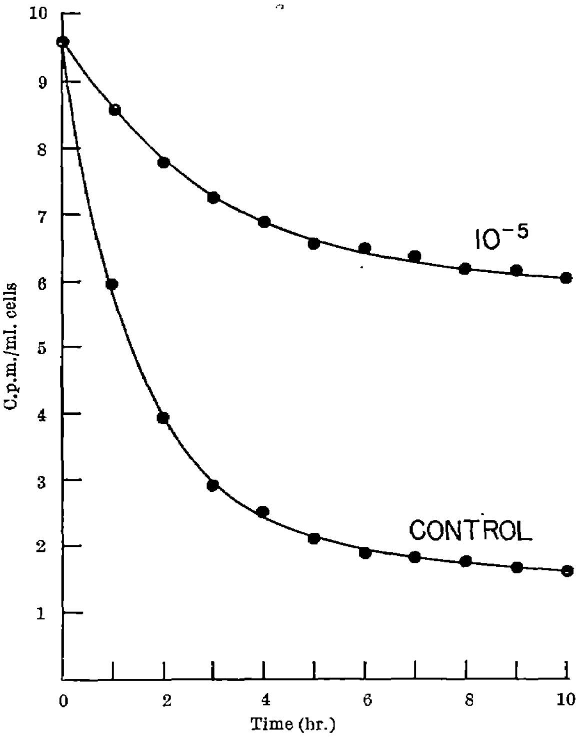

Fig. 2. Typical efflux experiment showing the effect of ouabain on sodium efflux. Fresh, heparinized human blood was incubated with labelled sodium chloride for 1 hr. The radioactive cells were separated and added to a non-radioactive, plasma-like, isosmotic medium to produce a mixture with a relative cell volume of approximately 45 per cent

Influx and efflux experiments have been carried out at 37° C. on fresh, heparinized, whole human blood using sodium chloride labelled with sodium-24 and the methods previously described[2,6]. Fig. 1 shows the results in a typical influx experiment. The concentration-range covered in eight such experiments was 10^{-4} to 10^{-11} mole ouabain/l. blood. These experiments indicate that inhibition is slight at concentrations between 10^{-11} and 10^{-9} mole/l. It increases sharply at 10^{-8} and appears to reach saturation at about 10^{-6} mole/l., though results are somewhat variable at higher concentrations.

This marked effect may represent either an increase in influx of sodium-24 or a decrease in efflux of sodium-24, since either process would result in accumulation of radioactivity in the cells. Efflux experiments (in which cells previously incubated with sodium-24 are placed in a non-radioactive medium) afford a method of discrimination between these alternatives. Four efflux experiments were carried out in the concentration-range of 10^{-5} to 10^{-7} mole ouabain/l. blood. Fig. 2, which is typical of these experiments, shows that the efflux of radioactivity does indeed decrease under the influence of the drug. From about 6 hr. onward, the efflux appears to be small and quite uniform. Thus it appears that a large portion of the gain in cell sodium-24 may be attributed to decreased efflux from the cells. A similar conclusion has been reached by Glynn[3] on the basis of a comparison of influx experiments on cold-stored human red cells with efflux experiments on normal ones.

The results for net gain of sodium may be compared with the net loss of potassium as previously measured under similar experimental conditions[2]. These

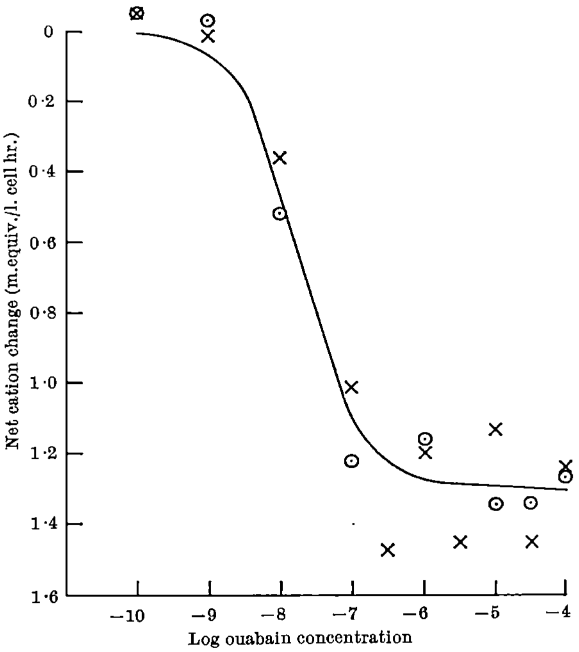

Fig. 3. Relationship between net cation shift (×, potassium loss and ⊙, sodium gain) and ouabain concentration. The results for potassium loss and the dose response curve are taken from a previous paper (ref. 2)

results are shown in Fig. 3, in which the dose response curve is that previously obtained for potassium. It can be seen that there is no demonstrable difference between gain of sodium and loss of potassium as ouabain concentration is varied over a million-fold range. 50 per cent inhibition of the affected potassium influx (which is about 80 per cent of the total potassium influx) was reached at an ouabain concentration of $3{\cdot}2 \times 10^{-8}$ mole/l. Since the curve describes the effect on sodium as well as that on potassium, the same half-inhibition value is reflected in the accumulation of sodium.

These experiments show a 1 : 1 correspondence between downhill net movements, that is, sodium influx and potassium efflux, when transport is maximally inhibited by ouabain. This makes it difficult to believe that the movement of these ions is not regulated by a common mechanism, since the electrochemical driving force is different for each cation. The correspondence is also apparent at the 50 per cent inhibition point, when processes of uphill and downhill transport both participate. Certainly, these observations could be used for supporting the proposal of Harris and Maizels[7] that red-cell sodium and potassium transport systems are linked. Glynn[8] has also reached the conclusion that there is a 1 : 1 linkage between 'active' sodium efflux and 'active' potassium influx. (Post and Jolly[9] have studied uptake of potassium by cells that have been stored at 2° C. for periods up to 25 days. They also find a linkage, 2 atoms of potassium being transported inwards for every 3 atoms of sodium transported outwards. These studies are not comparable with the present ones, since the cells had been stored for many days and their internal cation concentrations were very different from normal.) Glynn's conclusion depends upon studies of glucose-sensitive fluxes in cells suspended in a medium containing almost no potassium. These fluxes include only about half the total sodium flux; an appreciable fraction of the remainder, according to Glynn, moves by the process of exchange diffusion. The present results are compatible with those of Glynn, though ouabain may affect both Glynn's 'active' sodium efflux and the exchange diffusion process. Since ouabain apparently does not affect the supply of energy, but is presumed to act on the transport mechanism, the present results suggest that the linkage is effective at a step beyond supply of energy, probably at the cell surface, on the sites assumed important for the first step in entrance of potassium into the cell[2]. However, in both Glynn's and the present work, linkage has been demonstrated in cells that have been subject to a perturbation, such as deprivation of extracellular potassium, or the addition of ouabain. Thus, caution must be used in interpreting such observations as illustrative of the normal transport of ions across the red-cell membrane.

Lithium Retention in Ascites Tumour Mice

Mice inoculated with an Ehrlich Lettré ascites tumour have a life-span of 2–3 weeks. In the course of ionic balance studies on such mice we noticed that these animals, after being given lithium, tended to retain more than normal controls. Daily lithium injections (1 ml. of 150 m.equiv./l. lithium chloride subcutaneously) were started on either the fifth or tenth day after inoculation, and were continued for a further four days. Food and water were given *ad libitum*. On the fifth day the mice were lightly etherized, samples of the ascitic fluid were withdrawn and blood was obtained by cardiac puncture. Plasma, red blood cells, ascites supernatant fluid and tumour cells were analysed for sodium, potassium and lithium using a Beckman flame spectrophotometer. All mice were examined for the presence of macroscopic secondary deposits.

The control mice showed a relatively constant level of red-cell and plasma lithium with this treatment. The mean plasma-level was 0·23 m.equiv./l. ± a standard error of 0·013 (15 observations). The red-cell level was 0·434 m.equiv./l. ±0·022. Thus the mean ratio of Li+(out)/Li+(in) was 0·53.

The tumour mice had consistently higher levels of plasma and red cell lithium but the results showed considerable scatter. The mean plasma lithium-level was 0·96 m.equiv./l., and the mean red-cell level was 1·15 m.equiv./l., giving a ratio of Li^+(out)/Li^+(in) of 0·83. However, the range of plasma values was from 0·27 to 2·8 m.equiv./l. The lowest plasma-level in the ascitic mice was higher than the mean control level, but we feel that the tumour mice cannot be regarded as a homogeneous population. The overall plasma to cell ratio was higher in the tumour mice than in the controls, but it was noted that where the plasma lithium-level was low the tumour mice showed a ratio similar to the controls, and as this level rose the ratio rose.

The lithium-level of the supernatant fluid obtained by centrifuging the ascites contents was very similar to that of the plasma in the same mouse. The lithium-content of the tumour cells was the same as, or slightly less than, the supernatant level. The cells appear to contain large amounts of lipid material which may complicate the estimate of ionic distribution between cells and supernatant.

The amount of trapped fluid remaining in the cell mass after 60 min. centrifugation of the ascites contents at 1,150g was estimated using radio-iodinated serum albumin, and was found to be 20–24 per cent of the total mass. This figure is somewhat greater than that found by Maizels *et al.*[1].

The mean sodium-content of the tumour cells was 75·6 ± 2·3 m.equiv./kgm. (25 observations). The mean sodium-level of the supernatant was 149 ± 2·0 m.equiv./l. and from this figure and the estimate of the trapped fluid the intracellular sodium-level was calculated to be 54 m.equiv./l. The mean potassium-level of the cells was 73·0 ± 3·1 m.equiv./l. (25), and the potassium-level of the supernatant fluid, which was very variable, gave a mean value of 18·5 m.equiv./l. Thus the intracellular potassium-level was estimated as 88·5 m.equiv./kgm. These figures are noticeably different from those found for the red-blood cell.

It will be noted that the mean supernatant fluid sodium-level is 15 m.equiv./l. lower and the mean potassium-level is 13 m.equiv./l. higher than the corresponding plasma figures. These differences may be due to ionic movements along the respective concentration gradients between the time of removal of the ascites fluid from the animal and its separation by centrifugation. This was checked in one animal by removing ascites fluid, immediately filtering some of it through a Whatman No. 42 filter paper and centrifuging the rest in the usual manner. The filtered cell-free fluid had a potassium concentration of 5·4 m.equiv./l., the same as plasma, whereas the centrifuged supernatant fluid had a potassium concentration of 7·7 m.equiv./l. This particular ascites had a cell content of 10 per cent so that the potassium leakage from the cell was of the order of 20 m.equiv./l. of the initial cell potassium. As most of the ascites in the experimental series had cell contents of 30–50 per cent the discrepancy between the supernatant fluid and plasma potassium-levels is likely to be explicable on the basis of ionic diffusion across the cell wall after removal from the animal.

The crude mean red-cell sodium was 24·4 ± 1·7 m.equiv./l., and the plasma sodium was 164 ± 2·2 m.equiv./l. (18 observations). The trapped plasma volume was 3 per cent, giving a corrected intracellular level of 21 m.equiv./l. The mean plasma potassium-level was 5·3 m.equiv./l., and the mean corrected intracellular potassium for the red cells was 123 m.equiv./l.

In general, the plasma potassium-level of the tumour mice was similar to that of the controls except in mice in the terminal stages, where levels were as high as 9·0 m.equiv./l. This was probably an agonal phenomenon.

Further experiments were carried out in which lithium was added to the drinking water at a concentration of 30 m.equiv./l. for 4 days prior to bleeding. Here again the tumour mice had higher plasma lithium-levels than the controls, and again there was more scatter in their levels than in the control animals. The control mice had mean levels of 0·77 and 0·66 m.equiv./l. lithium in the plasma and red cells respectively, compared with corresponding levels of 1·52 and 1·72 m.equiv./l. in the tumour mice. One cannot exclude the possibility of a greater lithium intake by the tumour mice in this type of experiment. It is noteworthy, however, that the ratio of plasma to red-cell lithium was higher in all drinking experiments than when the mice received lithium by injection. These mice had access to the lithium solution until immediately before bleeding, while the injected mice had their last injection some 20 hr. before bleeding. Thus the finding of a proportionately greater extracellular phase may be easily explicable.

A third type of experiment was performed to ascertain whether lithium treatment altered the ionic content of the tumour. Twelve mice were inoculated with the same sample of tumour and four days later half were given a solution of 25 m.equiv./l. lithium chloride to drink. All were killed after a further six days. We were unable to detect any significant difference in the sodium and potassium-level of the blood or the tumour between the control and treated mice. The latter had the usual lithium distribution. Under these conditions lithium does not appear to alter the ionic balance of the tumour mouse.

Given a constant intake it is clear that tumour-bearing mice retain more lithium over a period than normal controls. This must be a reflexion of decreased renal excretion in the tumour-bearing animals. It is not possible to decide from this work whether the retention of lithium is a specific renal effect, possibly hormonal, exerted by the tumour, or whether it is merely due to the mechanical effect of the accumulating ascites on the kidney. It may be that renal blood flow is greatly reduced in these animals.

Oxidative Metabolism and Puparium Formation in the Ebony Mutant of *Drosophila melanogaster*

WE have recently reported[1] differences between the oxidative metabolism of the wild type and the ebony mutant of *Drosophila melanogaster*. (The latter has a paler and softer puparium than the wild type.) As it was found earlier[2] that dehydrogenase activity of homogenates of prepupæ at the time of pupation is 26 per cent higher in ebony than in the wild type (reciprocal values of the average decoloration time, given by homogenates of 10 prepupæ in 0·2 ml. 0·02 per cent methylene blue: 0·0469 for ebony, 0·0346 for wild), while the oxygen consumption of intact prepupæ at the same stage is only 18 per cent higher in ebony than in the wild type (average oxygen uptake per hour per 1 mgm. dry weight, 4·52 µl. for ebony, 3·71 µl. for wild type; measurements made by Miss Mary Hartman) it was inferred that during pupation the redox potential is lower in ebony than in the wild type.

As it was reported by Ohnishi[3] that tyrosinase activity at the same time is about twice as high in the wild type as it is in ebony, it was thought that these findings, taken together, support Dennell's concept[4] that tyrosinase activity is controlled by dehydrogenases, which lower the redox potential and thereby inhibit tyrosinase. Karlson and Wecker's results[5], according to which not the dehydrogenase system but rather the activity of the cytochrome system is responsible for keeping tyrosinase activity at bay, was disregarded in view of the higher percentage difference between dehydrogenase activities as compared with the difference between total oxygen consumption of the two types. This failed to take into consideration that dehydrogenase activity and total oxygen consumption are not comparable values, but the former represents only a fraction of the latter.

If we assume that total oxygen consumption is made up of dehydrogenase, cytochrome and tyrosinase activity in the same proportion in *Drosophila* as—according to Karlson and Wecker—in *Calliphora* (at puparium formation roughly half due to tyrosinase activity and a quarter each due to cytochrome and dehydrogenase activity respectively) then the 26 per cent higher dehydrogenase activity observed in ebony prepupæ would account only for a 6 per cent higher total oxygen consumption. But as this value was found to be 18 per cent higher in ebony than in the wild type at pupation, it is to be concluded that a greater part of this 18 per cent difference (roughly about two-thirds, if the ratios are the same as in *Calliphora*) must be due to a higher cytochrome activity and only a small part to a greater activity of the dehydrogenases. This indicates that the concept of Karlson and Wecker (inhibition of tyrosinase by cytochrome respiration, through competition for quinones, which are needed for the induction of tyrosinase activity), rather than the explanation of Dennell (inhibition by dehydrogenase activity and subsequent lowering of the redox potential) is the correct one.

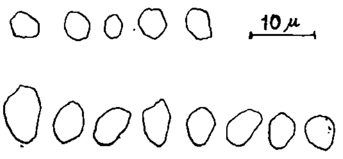

Fig. 1. Outline drawings (camera lucida) of nuclei in the corpus allatum portion of Weismann's ring. Upper row, wild type; lower row, ebony

In any event, the lower tyrosinase activity in ebony, as measured by Ohnishi and manifested in the lack of tanning of the puparium, is associated with a higher rate of respiratory metabolism. We have suggested that this increased metabolism is due to an increased activity of the juvenile hormone, produced by the corpus allatum portion of Weismann's ring, as we found the nuclei of the cells in this portion significantly larger in ebony than in the wild type (Fig. 1), and interpreted this as a sign of greater endocrine activity. The ratio of the average nuclear diameters (4·60μ for wild, 6·25μ for ebony) is almost exactly 3 : 4. Taking into consideration that somatic cells of *Drosophila*, especially those of a glandular nature (like the salivary gland cells), are known to be polytenic in various degrees[6] we venture now to suggest that the primary effect of the ebony gene is perhaps to increase the degree of polyteny in the cells of the corpus allatum portion of Weismann's ring. If this could be proved, one would have an attractive picture of the chain of physiological–biochemical processes leading from the ebony gene to the external character of the pupa, which it controls : (1) increased multiplication of chromonemata in the nuclei of the corpus allatum (either at a faster rate, or by a prolonged period) ; (2) higher degree of polyteny of these nuclei ; (3) increased synthesis of the juvenile hormone ; (4) higher rate of respiratory metabolism ; (5) greater inhibition of tyrosinase activity ; and (6) imperfect ('juvenile') tanning of the puparium.

Inhibition of Growth and Respiration of *Ophiobolus graminis* var. *avenae* and *Aspergillus niger* by Cystine

The fungus *Ophiobolus graminis* infects the roots of wheat and barley, but does not infect oats. *O. graminis* var. *avenae*, however, infects oats as well. Both strains grow well in a simple medium containing potassium dihydrogen phosphate, sodium hydrogen phosphate, magnesium sulphate, glucose, thiamin, biotin, and a nitrogen source, usually ammonium nitrate or sulphate, or amino-acids. Most of the amino-acids give good growth when used singly as sole nitrogen source. Growth of *O. graminis* is stimulated by cysteine and cystine added to the basic medium containing ammonium nitrate up to a concentration of 0·01 *M*. Without an inorganic nitrogen salt, growth is very good with 0·04 *M* cysteine. Growth of var. *avenae* is inhibited by cystine and cysteine at concentrations as low as 10^{-6} *M* and at no concentration is growth stimulated[1]. Growth of *Aspergillus niger* is also inhibited by cystine and cysteine[2]. *Penicillium notatum* has also been described as susceptible to inhibition of respiration by cystine[3].

Some preliminary information about this inhibition in *O. graminis* var. *avenae* and *A. niger* (which both behave identically) was obtained during an attempt to correlate specificity of parasitism with metabolic differences and is reported here.

With both fungi substitution of 0·5 per cent ammonium nitrate by 0·5 per cent ammonium sulphate prevents inhibition. This protection is complete at 0·5 per cent and partial at 0·1 per cent ammonium sulphate. On adding 0·1 per cent potassium nitrate or potassium nitrite to the ammonium

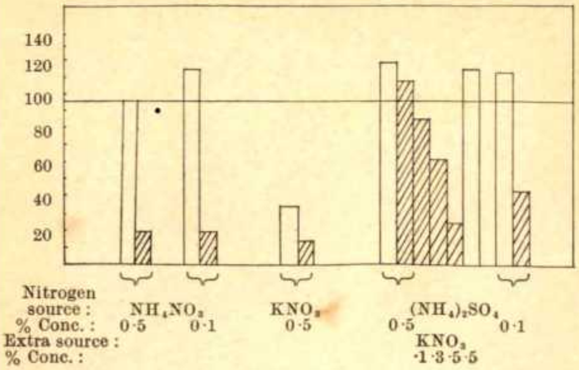

Fig. 1. Relative growth of *O. graminis* var. *avenae* showing effect on cystine inhibition of different sources of nitrogen : shaded, with 10^{-4} *M* cystine ; unshaded, without cystine

sulphate medium full inhibition again occurs (Fig. 1). The *p*H does not vary appreciably during growth in these media.

2×10^{-4} *M* aspartic acid or glycine added to the ammonium nitrate medium fully prevents inhibition by 10^{-4} *M* cystine. Serine and alanine are partially effective, other amino-acids ineffective.

Molybdenum (as sodium molybdate) added to the ammonium nitrate medium fully prevents inhibition.

Cysteine inhibits respiration of *O. graminis* var. *avenae* and *A. niger* in manometer flasks containing phosphate buffer and 2 per cent glucose only. Inhibition occurs within 30 min. of adding 2 mgm./ml. cysteine. It is equally great with no nitrogen source or with nitrate and can again be prevented by addition of ammonium sulphate (20 mgm./ml.) in absence of nitrate or nitrite ions, or of aspartate or glycine (1 mgm./ml.) or molybdenum (0·02 mgm./l.).

Since the inhibition by cystine is as great in the absence of NO_3^- ion as in its presence the effect of nitrate on inhibition appears to be an indirect one, in that it prevents the NH_4^+ ion exerting its usual protective effect, perhaps by interference with uptake. These observations are summarized in Table 1. The type of inhibition indicated is a metal chelation effect connected with an early stage in nitrogen metabolism. The reversal of inhibition by molybdenum suggests an effect on enzymes of the nitrate-reducing sequence[4] ; but this is difficult to reconcile with the results of the respiration experiment.

BACTERIOLOGY

Formation of 'Protoplasts' in Mutant Strains of *Salmonella* induced by Galactose

IN 1932 Murase[1] in our laboratory isolated a peculiar mutant strain from aged broth cultures of *Escherichia coli* incubated at 37° C. This mutant had a characteristic colonial morphology on agar plates containing lactose, and because of its apparent resemblance to Massini's classical *Bacterium coli mutabile*[2] was called 'mutabile-type' by him. Since then, mutant strains having similar properties have been isolated from aged broth cultures of many strains of *E. coli*, *Shigella*, *Salmonella* and '*Paracolon*' groups, and many investigations on this particular type of mutation have been carried out in our laboratory. The results obtained may be summarized as follows[3,4].

(1) 'Mutabile-type' (*M*) mutants form convex colonies on ordinary nutrient agar plates, but when inoculated on agar plates containing galactose (or in some cases oligosaccharides containing galactose, namely, lactose or raffinose), they give rise to very flat colonies, with somewhat concave centres, and several papillæ appear on these colonies if incubation is prolonged.

(2) Wild-type strains are usually galactose-fermenting, but *M* mutants are consistently non-fermenters of galactose. (Massini's *B. coli mutabile* cannot ferment lactose, but it usually ferments galactose.)

(3) The growth of *M* mutants is strongly inhibited by the presence of even low concentrations of galactose, and this inhibition can be reversed by glucose. (Massini's *B. coli mutabile* is not inhibited by galactose.)

(4) Thus *M* mutants must be considered to be quite distinct in their nature from Massini's *B. coli mutabile*. Though *M* mutants were isolated from the aged broth cultures of many strains of the family Enterobacteriaceae, the frequency of their development varies greatly with strains used, conditions of incubation, and so on.

We have studied the mechanism of the inhibitory action of galactose on these mutants. The strain used was an *M* mutant of *Salmonella enteritidis* strain No. 11.

In the first series of the experiments, the mutant strain was grown with shaking in various liquid media—nutrient broth, salts–citrate–ammonium medium (Davis and Mingioli's minimal medium was modified by the substitution of 0·5 per cent sodium citrate for glucose), etc.—and D-galactose (Difco) was added to the final concentration of 0·1 per cent at the exponential phase of growth. Growth continued for about 30–90 min. at a slightly reduced rate, and then marked lysis was observed. But when the cells were kept in the non-growing condition, either by the addition of chloramphenicol (25 μgm./ml.) or by the removal of essential nutrients—by omitting citrate or ammonium salt from salts–citrate–ammonium medium and by omitting histidine in the case of a histidine-requiring mutant of this strain—galactose could not exert any effect on these mutant cells ; no lysis was observed and the cells remained fully viable even at high concentrations of galactose. Thus the residual growth after the addition of galactose seemed to be a prerequisite for the extensive lysis to occur. This finding, together with the facts that the M mutant cells grown in the presence of low concentrations of galactose show altered staining properties and degenerated forms[1,3,4], reminded us of some resemblance to the mode of action of penicillin on bacteria, in which case it has already been reported that: (1) penicillin induces lysis after some residual growth; (2) non-growing cells are resistant to the action of penicillin; (3) the cells grown in the presence of penicillin show various degenerate forms.

In the case of penicillin it was also reported that, when added to the suspension of *E. coli* growing in suitable hypertonic media, the bacterial cells are converted into the so-called 'protoplasts'[5,6]; spherical, osmotically fragile, yet viable (if appropriately treated) bodies. So the effect of galactose on M mutant cells was tested using a hypertonic medium. M mutant cells were grown in ordinary nutrient broth and in 'Carbowax-magnesium broth' (broth supplemented with 7·5 per cent (w/v) 'Carbowax 4,000' and 0·01 M magnesium sulphate)[7], and galactose (0·1 per cent) was added at their exponential phase of growth. As seen in Fig. 1, 'Carbowax 4,000' with magnesium ions completely prevented lysis induced by galactose. When these cells were examined under a phase-contrast microscope it was discovered that, 2–3 hr. after the addition of galactose, most of the cells in 'Carbowax'-magnesium broth were transformed into large, spherical bodies (Fig. 2), indistinguishable from the 'protoplasts' of this strain obtained by the action of penicillin in the same medium. If these 'spherical bodies' were diluted with distilled water, rapid clearing was observed, indicating their osmotic fragility. In order to confirm this finding, they were diluted serially either with distilled water or 'Carbowax'-magnesium broth, and 1 ml. aliquots of their 1 : 10^{5-7} dilutions were mixed in Petri dishes with molten 'Carbowax'-magnesium broth agar at 45° C. After overnight incubation, it was found that, when diluted with distilled water, they produced only $1 \cdot 9 \times 10^{-2}$ the number of colonies produced when they were diluted with 'Carbowax'-magnesium broth. In the control experiment with intact cells of this strain no difference in viable counts was observed between these two diluents.

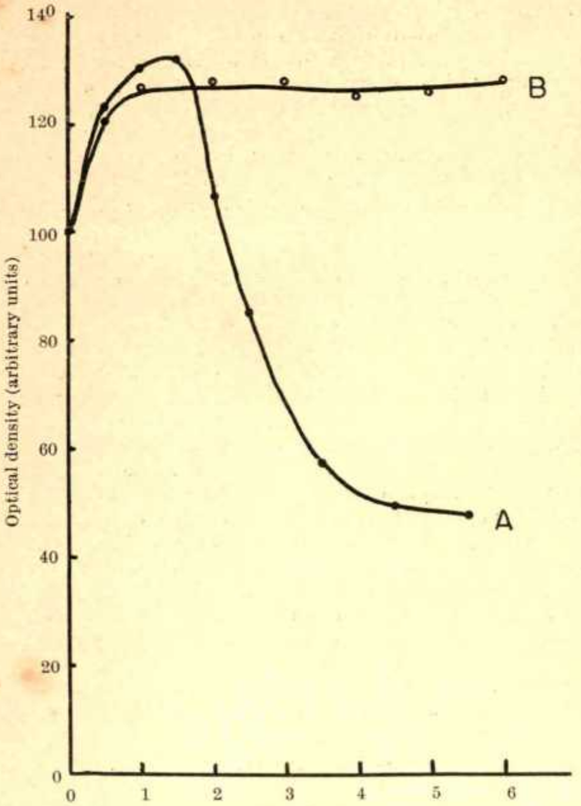

Fig. 1. Lysis of M mutant cells by galactose and its protection by 'Carbowax 4,000' and magnesium sulphate. Cells were incubated at 37° C. with gentle shaking either in nutrient broth (*A*) or in 'Carbowax'-magnesium broth (*B*). Optical density was measured at 660 mμ and expressed as relative values. The time of addition of galactose is shown as zero time

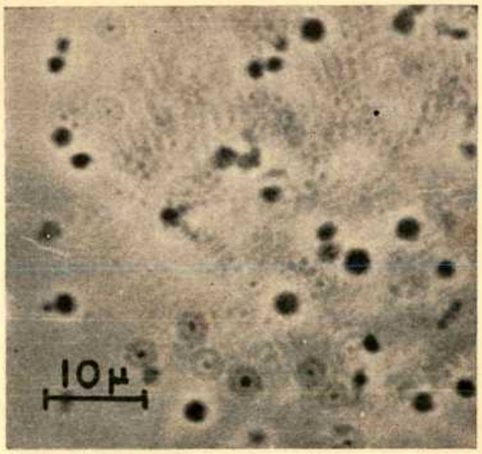

Fig. 2. 'Spherical bodies' of M mutant cells induced by galactose. M mutant cells were incubated for 2 hr. in 'Carbowax'-magnesium broth containing 0·1 per cent galactose

Results similar to those described above were also obtained with an M mutant of a strain of *Salmonella typhimurium*. As in the case with penicillin[5], the most plausible explanation of the action of galactose is the inhibition of some intermediate process of cell-wall synthesis, but other possibilities remain which cannot be excluded at present. These points are now under investigation, and will be reported later with the details of the present study.

Thanks are due to Prof. D. Ushiba and Dr. K. Kinjo for their encouragement during this work.

Isolation of Two Types of *Pasteurella haemolytica* from Sheep

IN the course of studies on *Pasteurella haemolytica* isolated from cases of ovine pneumonia and septicæmia it has proved possible to place each strain examined so far into one of two main groups which, though closely similar, are distinguishable by certain *in vitro* characteristics. The occurrence of two types as described in this communication appears to be a different phenomenon from the colonial variation of

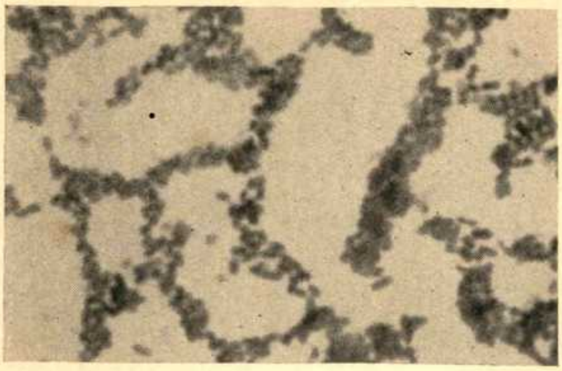

Fig. 1. Smear of T strain made in distilled water. (× 750)

Past. haemolytica recently described by Biberstein *et al.*[1]. For convenience the two forms will be referred to here as T strains and A strains, and a description of some distinguishing features is now given.

T *Strains.* 24 hr. colonies on blood agar measure up to 2 mm. in diameter. When viewed by transmitted light they are seen to possess large dark brown centres, the colour fading markedly towards the peripheries. When smears are made in distilled water from smooth colonies the bacteria generally show a strong tendency to become arranged in the lace-like pattern depicted in Fig. 1. This pattern is readily seen under the low power of the microscope. Smears made in saline show even dispersal of organisms.

Fermentation reactions are carried out in the medium recommended by Bosworth and Lovell[2]. This consists of peptone water containing 10 per cent broth with 7·5 per cent bromthymol blue and 1 per cent of the fermentable substance. The only tubes considered as positive are those which become completely yellow. All strains give a positive reaction in trehalose fermentation medium after two days incubation. The reaction in arabinose medium is negative up to the tenth day.

Growth curves in broth cultures inoculated with single colonies reach their maximum levels at about the sixth hour of incubation. The viable counts of such cultures then fall relatively slowly up to the twenty-fourth hour.

T strains are only moderately sensitive to the action of penicillin *in vitro*.

A *Strains.* Colonies growing on blood agar often tend to be rather smaller than T colonies. When viewed by transmitted light they show an even lightish-grey colour. There is sometimes a small, clearly demarcated central thickening. Smears made in distilled water usually show even dispersal of bacteria and a number of weakly staining 'ghost' forms.

All strains give a positive reaction in arabinose fermentation medium by the seventh day of incubation but remain negative in trehalose up to the tenth day.

Growth curves are different from those of T strains when broths are inoculated with comparable numbers of viable A organisms. Similar maximum viable counts are again obtained at about the sixth hour and the difference occurs afterwards as a result of the rapid and marked reduction in numbers of living A bacteria. At the twenty-fourth hour of incubation the differences in viable counts between A and T strains are only occasionally less than ten-fold and usually much greater. At this time there is no appreciable difference between turbidities of A and T broth cultures, neither is there any evidence of excessive clumping of bacteria. The pH of twenty-four hour A broth cultures is consistently slightly higher than that of T cultures.

A strains are considerably more sensitive than T strains to the action of penicillin *in vitro*.

Source of cultures. All 15 strains isolated from different outbreaks of lamb septicæmia[3] were of the T variety. No A strains have as yet been obtained from typical septicæmias. More than 20 A strains were derived in pure culture from sheep pneumonias. Four cases of pneumonia have been encountered in which mixtures of T and A strains were isolated from lung tissue, the liver, spleen and heart blood being sterile. In each of these cases A organisms predominated although the numbers of T organisms present were considerable.

Production of 5-Keto-gluconic Acid by a Species of *Pseudomonas*

In the latest edition of "Bergey's Manual of Determinative Bacteriology"[1], several authors are cited as supporting the claim that *Pseudomonas* strains which attack glucose do so oxidatively with the production of gluconic and 2-keto-gluconic acids, whereas *Acetobacter* strains, many of which are morphologically similar to members of the *Pseudomonas*, oxidize glucose to gluconic and 5-keto-gluconic acids.

In a recent study carried out at the Torry Research Station, Aberdeen, on some fifty *Pseudomonas*-like strains of bacteria isolated by previous workers[2-4] from fish, it was found that two of these strains produced 5-keto-gluconic acid from the oxidation of glucose. In the usual peptone water plus 1 per cent glucose medium, a strong acid (but no gas) reaction was given on 3-days incubation at 30° C. These cultures reduced Benedict's reagent in a few minutes at 25° C.—a feature, according to Militzer[5], characteristic of 5-keto-gluconic acid.

The products of glucose oxidation were separated by ascending chromatography on Whatman No. 1 paper (10 in. × 10 in.), using the solvent system of McFarren *et al.*[6] (ethyl acetate/pyridine/water, 25 : 30 : 15); 5-keto-gluconic acid ran as a strongly reducing spot at R_F 0·08, easily identified with the aniline oxalate reagent of Hough *et al.*[7], with which it gives a strong yellow spot, on heating for 5 min. at 105° C. With this reagent, gluconic acid gives no reaction, and 2-keto-gluconic acid forms an intense red spot. Only the two cultures which reduced Benedict's reagent at 25° C. gave this characteristic spot.

When cultured in 0·5 per cent peptone water containing 0·5 per cent ethanol, previously sterilized by Seitz filtration, neither strain produced acid or gas, even on prolonged incubation for 3 weeks at 30° C., although growth of both was excellent after

3 days. A strain of *Acetobacter aceti* cultured in this same medium produced acid in 3 days at 30° C.

Neither strain produced pigment on any medium, but morphologically were typical *Pseudomonas* strains; they were Gram-negative, polar flagellate bacilli, attacking glucose only under aerobic conditions, using the technique developed by Hugh and Leifson[8].

Biochemically, in some fifty tests, the two strains differed from each other with respect to the following reactions: tri-butyrin hydrolysis; fucose utilization; reduction of nitrate and growth in litmus milk. In addition, one strain grew at temperatures of 0–37° C., the other 0–30° C.

It is considered that, in view of their overall similarity to each other, they should be considered strains of the same *Pseudomonas* species; and since no description of such a species appears to exist in the most recent edition of "Bergey", it may well turn out to be a new one.

A full description of the morphology and biochemistry of this species will be published at a later date.

Synthesis of Deoxyribonucleic Acid by Phage-infected *Escherichia coli* in the Presence of Mitomycin C

IN a previous communication Shiba *et al.*[1] presented evidence that synthesis of deoxyribonucleic acid in *Escherichia coli B* was completely inhibited in the presence of mitomycin *C*, while ribonucleic acid and protein formation were unaffected as compared with that of a culture not exposed to the antibiotic. This communication shows that the impaired synthesis of deoxyribonucleic acid in cells treated with mitomycin *C* can be promptly restored by infection with bacteriophage *T2r*.

The crystalline mitomycin *C* used in these experiments was supplied by the Kyowa Fermentation Industry Co., Ltd., Tokyo, through the courtesy of Dr. S. Shiba of this University. Determinations of deoxyribonucleic acid, ribonucleic acid and protein were carried out by the diphenylamine, orcinol and Folin reactions, respectively.

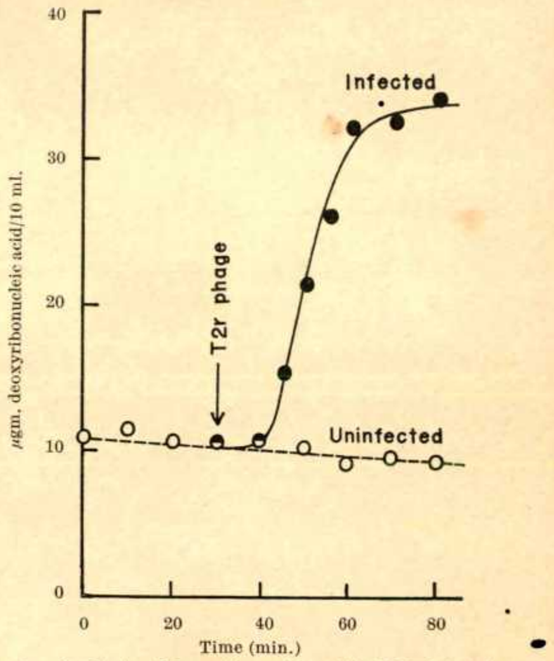

Fig. 1. Synthesis of deoxyribonucleic acid of *T2r*-infected or uninfected cells in the presence of mitomycin *C*. Cells harvested during the logarithmic phase were resuspended in fresh medium containing 10 μgm./ml. of mitomycin *C* at a concentration of 5 × 10⁸ cells/ml., and incubated at 37° C. with shaking. After 30 min., one portion of the bacterial suspension was infected with a five-fold multiplicity of *T2r* phage, and another portion was incubated without infection as control. 10 ml. aliquots of the suspension were taken at the intervals shown and analysed for deoxyribonucleic acid

Cells grown in a glucose – salts synthetic medium with aeration were harvested during the logarithmic phase, and resuspended in a similar fresh medium. Tubes containing 10 ml. of the cell suspension (series *A*, 5×10^8 cells/ml.; series *B*, 5×10^8 cells plus $2 \cdot 5 \times 10^9$ *T2r* phage per ml.; series *C*, 5×10^8 cells plus 1×10^5 *T2r* phage per ml.) with various levels of mitomycin *C* as shown in Table 1 were incubated with shaking at 37° C. for 30 min. Series *A* (uninfected cells) and series *B* (infected cells) were subjected to the assay of nucleic acids and protein. Viability of the cells and infectivity of phage were measured by plating the sample of series *C*.

As shown in Table 1, exposure of a growing culture of uninfected cells to 10 μgm./ml. of mitomycin *C* caused selectively an inhibition of the net synthesis of deoxyribonucleic acid. The level of mitomycin *C* is much higher than that proposed by Shiba *et al.*[1], indicating that the strain used in these experiments (which was kindly furnished by Dr. A. D. Hershey) was more resistant to the antibiotic. While mitomy-

cin C completely inhibited the formation of deoxyribonucleic acid in uninfected cells, its synthesis in cells infected by bacteriophage $T2r$ could proceed without any inhibition under the same conditions. In addition, synthesis of deoxyribonucleic acid was resumed upon infection of bacteria pretreated with mitomycin C by bacteriophage (Fig. 1). Notwithstanding the increase in deoxyribonucleic acid in cells infected by bacteriophage $T2r$, it was found that the phage titre after incubation at the same level of mitomycin C was only about 20 per cent of the control (Table 1). Although the values of phage titre given in Table 1 were for an actual multiplicity of infection of 1 (average multiplicity of 0·0002) compared with 5 for the chemical results, we have obtained similar results for phage production at the higher multiplicities.

These results are reminiscent of the facts that bacteria damaged by ultra-violet irradiation[2] or mustard treatment[3] can recover their ability to synthesize deoxyribonucleic acid when infected with phage. However, in the case of inhibition by mitomycin C, removal of the antibiotic is not required to permit the infected bacteria to synthesize deoxyribonucleic acid. Therefore, it is possible that an alternative pathway of formation of deoxyribonucleic acid, resistant to mitomycin C, may be present in the infected cells.

We wish to express our appreciation to Prof. H. Kikkawa and Dr. B. S. Strauss for their interest and encouragement in this work.

Synthesis of Cellulose in Ethanol Extracts of *Acetobacter xylinum*

FORMATION of bacterial cellulose in cell-free fractions of homogenates of *Acetobacter xylinum*, supplemented by either adenosine triphosphate[1,2] or uridine diphosphoglucose[3], has recently been reported. Such homogenate fractions are necessarily complex, and unequivocal identification of the immediate precursor of cellulose might be easier if a cell-free extract of cultures of this bacterium, which retains the capacity to form cellulose, could be prepared. This communication describes the preparation of such an extract.

Cells free from cellulose were prepared as described by Hestrin and Schramm[4], except that they were not dried from the frozen state but stored as a suspension in phosphate citrate buffer, pH 6·0, 0·01 M in phosphate, 0·003 M in citrate. The cells from 50 ml. of suspension, containing approximately 10^9 viable cells/ml., were washed once by centrifugation with 50 ml. of 0·02 M acetate buffer, pH 5·0, and the pellet redispersed in 6 ml. of the same acetate buffer. Three 2·5-ml. aliquots of the washed cell suspension were each incubated by shaking for 5 min. at 35° C. with 2·5 ml. of 0·02 M acetate buffer, pH 5·0, plus 0·8 ml. of 2 per cent glucose in the same buffer. After incubation, each aliquot was poured into 20 ml. of rapidly stirred absolute ethanol at room temperature and the cells removed by centrifugation immediately at 15,000g. The ethanolic supernatants were recentrifuged with a small amount of incinerated 'Celite 545' (Johns-Manville Co., New York). Finally, each aliquot was passed through a glass bacterial filter, Corning 60 UF, to remove any traces of cell debris or bacterial cellulose microfibrils.

The filtered extracts were treated as follows: aliquot A was evaporated to dryness at 40° C.; aliquot B was autoclaved for 15 min. at 17 lb. and evaporated as above; aliquot C was autoclaved, mixed with 1 ml. of the ultrafiltered supernatant of a suspension of washed *A. xylinum* cells which had been incubated for 5 min. in 2 per cent glucose, and then dried at 40° C.; finally, 1 ml. of the ultrafiltered supernatant was dried at 40° (aliquot D). The four residues were digested in 4 per cent sodium hydroxide for 10 min. at the temperature of boiling water[1,3,4], to remove a fraction of the non-cellulosic substance, diluted and the insoluble material centrifuged for 15 min. at 15,000g. Pellets were resuspended in 2 ml. of water and 0·05 ml. of the suspension placed on films of 'Formvar' floating on water. After suitable dialysis to remove residual sodium hydroxide, films carrying drops were mounted on grids, dried, shadowed with palladium–gold at an angle of 15° and examined in an electron microscope. Representative electron micrographs from each aliquot are shown in Fig. 1. The remainder of the pellet from each aliquot was washed thoroughly and hydrolysed in a sealed tube at 100° in 5 per cent sulphuric acid for 16 hr. The hydrolysate was neutralized with the ion-exchange resin 'Amberlite MB 1' (Rohm and Haas) and then chromatographed in butanol/pyridine/water (10 : 3 : 3). Free sugars were detected with alkaline silver nitrate. Aliquots A and C showed only one compound, which moved at the same rate as standard glucose. Only traces of this compound were detectable in aliquot B and none from D. Autoradiographs of chromatograms from a variety of

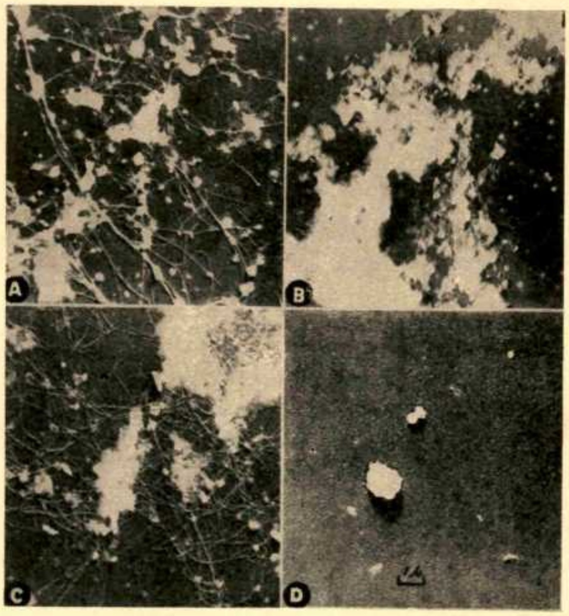

Fig. 1. Electron micrographs demonstrating formation of cellulose microfibrils from ultrafiltered ethanol extracts of active *Acetobacter xylinum* cultures: equal magnifications. Description of treatment of individual aliquots given in text

solvents, of ethanol extracts of active cultures metabolizing glucose uniformly labelled with carbon-14, so far have shown in these preparations no spots corresponding in position to those for cellobiose, cellotriose, cellotetrose, uridine diphosphoglucose or uridine diphosphate.

The fibrillar material from aliquot *A* (Fig. 1) is resistant to sodium hydroxide, yields only glucose as a component neutral sugar and has the typical morphology of bacterial cellulose microfibrils. It is formed from a precursor soluble in 80 per cent ethanol, during the evaporation of the extract, when the solution becomes predominantly aqueous. This formation of fibrillar material is almost prevented by prior autoclaving of the extract, but may be restored by addition of a portion of the extracellular medium of active cells. The precursor of cellulose microfibrils in the ethanol solution is therefore not destroyed by autoclaving for 15 min., but some accelerator of the process of microfibril formation must be. Presumably this accelerator is an enzyme. The presence of a few microfibrils in aliquot *B* indicates that the inactivation of the enzyme is not quite complete during this time. That the microfibrils do not come from the ultrafiltered supernatant of active cells is shown by the photograph of the grid from aliquot *D*. The presence of a substantial fraction of sodium hydroxide-resistant, non-dialysable, non-fibrillar material in each of the aliquots from ultrafiltered solutions should be noted because of its implications for interpretation of tracer experiments.

These results show: (*a*) 80 per cent ethanol extracts of active *Acetobacter xylinum* cells contain a compound which is converted rapidly to cellulose microfibrils when placed in water; (*b*) formation of cellulose microfibrils from this compound occurs in the complete absence of bacterial cell walls, as previously suggested[5]; (*c*) formation of microfibrils is accelerated by a heat-labile, extracellular substance in the medium of an active culture, presumably an enzyme. The results indicate also that neither uridine diphosphoglucose nor short β-glucosan chains are the immediate precursors of bacterial cellulose.

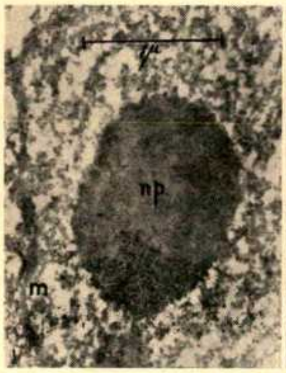
BIOLOGY

Ultrastructure of Nucleoli in Oocytes of *Patella coerulea*

A SPECIAL nucleolus, called 'Primärnucleolus' by Jörgensen[1], is always present during the growth of oocytes of *Patella coerulea*, while other nucleoli, called 'Amphinucleoli' by the same author gradually make their appearance. The 'Primärnucleolus' stains[2] red with Mallory's method and does not show the nucleolonema of Estable and Sotelo[3], while the 'Amphinucleoli' stain red at first, become blue later, show nucleolonemal elements and finally adhere to the nuclear membrane, where they gradually disappear. Previous research[4] suggested that this transition from red to blue might be due to a passage from a dense to a fluid state, which allows nucleolar substances to pass the nuclear membrane. No explanation was given of the presence of the nucleolonema in amphinucleoli and of its absence from the primary nucleolus. Electron microscope observations have been undertaken in order to check these results.

Fragments of the female gonad of *Patella coerulea* were fixed in a 1 per cent solution of osmic acid (buffered by Palade's method) and were embedded in a mixture of *n*-butyl and *n*-methyl methacrylate and sectioned with a Sjöstrand microtome. Preparations and observations were made at the Centre for Electron Microscopy at the University of Padua with a Siemens 'Elmiskop' I*a* apparatus. Throughout oocyte growth the primary nucleolus remains comparatively compact (Fig. 1) and does not present any particular structure which can be identified with the nucleolonema. It is composed of dark granules with a medium diameter of about 150 A., surrounded by granules of a lighter colour of approximately the same medium diameter (Fig. 1). These granules are more dense at the periphery. The outer surface of the primary nucleolus is not uniform, but shows strands extending into the nucleoplasm. These strands are composed of the above granules, which are also found in more or less conspicuous groups at a certain distance from the nucleolus. The same ultrastructure is shown by smaller nucleoli that are scattered inside the nucleus: they are amphinucleoli at the beginning of their formation[2].



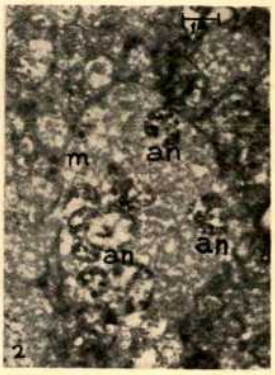


Fig. 1. Electron micrograph of the primary nucleolus (*np*) of oocytes of *Patella coerulea*; the nuclear membrane (*m*) is seen at the left. (× 9,000)

Fig. 2. Electron micrograph of the amphinucleoli (*an*) of oocyte of *Patella coerulea*; *m*, nuclear membrane. (× 2,250)

At later stages of their development the amphinucleoli have a quite different ultrastructure: they are then composed of rather thick and dark granules surrounding cavities of varying size (Fig. 2). The cavities correspond to intranucleolar vacuoles (these are also evident in later cytological preparations); the granules seem to be due to the aggregation of very small granular elements, the presence of which can also be observed in other regions of the same nucleoli. The outer surface of the amphinucleoli is more regular than the surface of the primary nucleolus.

Previous results obtained by platinum impregnation[2] are thus confirmed: during the growth of the oocyte of *Patella coerulea*, nucleoli of two types are present; one type shows evident nucleoolnemal elements, but the other type shows none.

Wischnitzer[5] observed with an electron microscope that the nucleolus of oocytes of *Triturus viridescens* "appears to maintain a compact consistency, but along the periphery strands project in all directions". He observed also that the nucleolus is formed by granules with an average diameter of about 150 A., surrounded by a matrix of lighter colour. André[6] also found that nucleoli of *Tegenaria parietina* oocytes are formed of numerous granules (100 A.) which are crowded together and form masses 0·1–0·2μ thick at the periphery. These masses are also found at a distance from the nucleolus. No mention is made of any threadlike structure resembling a nucleolonema. Finally, Serra[7], after an extensive comparative examination of nucleolar inclusions of plant meristem, oocytes of *Helix aspersa* and *Cepaea nemoralis*, and *Chironomus* salivary glands, reached the conclusion that "the nucleolonema is of the same rank as the vacuoles or other nucleolar differentiations : it is not a permanent structure in the nucleus nor does it necessarily exist in every nucleolus at all times".

However, according to Estable and Sotelo[3], the nucleolonema ought to be considered as a constant element of cellular structure. The above-mentioned results, as well as my own observations, lead to the conclusion that this is not so.

Lens Cells of the Calf in Continuous Culture

HUMAN and animal cells of various types in continuous culture are useful for studies of cellular biology and virus-cell interactions[1]. The need for strains of primary epithelial cells suggested the calf lens as a suitable tissue for investigating the possibility of establishing such cells in continuous culture. On December 28, 1956, both eyes were removed from a 3-months-old, male calf immediately after the death of the animal. Within 5 min. after enucleation, the lenses were removed from the eyes and were washed repeatedly with Hanks's balanced salt solution. The anterior capsule was dissected by circular incision posterior to the equator and the stroma was removed from the capsule ; the epithelium remained attached to the capsule. The capsule was supplied with 2 ml. of growth medium. The latter consisted of Hanks's solution, 30 per cent calf serum inactivated at 56° C. for 30 min., 0·5 per cent lactalbumin hydrolysate and 5,000 units of penicillin and 5 mgm. of dihydrostreptomycin/100 ml. The lens capsule was gently pipetted up and down in a coarse pipette so that small fragments, about 1 mm. in diameter, were obtained. The fragments of both lens capsules were planted without plasma in two screw-cap bottles of 200-ml. size. They were allowed to be attached to the glass for 3 min. Afterwards, the flasks were provided with 4 ml. of growth medium and they were incubated stationary at 36° C. After 7 days, 4 ml. of fresh growth medium was added per flask without removal of the old medium. Thereafter, 75 per cent of the culture fluid was renewed every seventh day for two weeks and then every third or fourth day.

Four weeks after primary explantation, initial outgrowth from some explants became visible. One month later, occasional islands of transparent, scarcely visible cells were noted. Growth progressed at a very slow rate. Eleven weeks after the initial planting, cells of one flask were detached from the glass and transferred to a new flask. After this transfer the growth-rate increased and three subcultures were made by use of mechanical detachment at intervals of 2 weeks. Later, cells were detached with 0·02 per cent versene to start one sub-line and with 0·5 per cent trypsin to start another. Proliferation continued for 8 months, then began to decrease. For some months both sub-lines were maintained with difficulty and were finally reduced to one culture. The culture flask was then provided with medium containing pooled fresh calf serum inactivated at 56° C. for 30 min. Thereafter, a marked growth response was noted, and the cells have continued to proliferate at a constant rate. At the present time, cultures are divided into 2–4 subcultures after 10–14 days of incubation. The calf lens cells (strain *T–5a*) have been maintained through 44 passages for two years.

No alterations in the appearance of the cells have been observed throughout the period of cultivation. Microscopic observation of the cells shows that they are 8 to 12 times larger than other cells in continuous culture maintained in our laboratory : HeLa, human kidney and reticulosarcoma[2], mouse and rabbit kidney. Morphologically, the size and the shape of *T–5a* cells are similar to those of surviving epithelium of bovine lenses described by van den Heuvel[3]. No characteristic type of cell has been observed ; some cells are polygonal, others are pyramidal, and a number are irregular in shape. The nuclei are oval and contain several nucleoli. Long mitochondria are conspicuous throughout the cytoplasm. Intercellular bridges between cells are regularly observed (Fig. 1). In contrast to other stable cell strains, division of calf lens cells is rarely seen. Possibly these cells require a relatively short period to complete mitosis. The *T–5a* cells are remarkably resistant to the action of trypsin. After incubation for 5 hr. at 37° C. in 0·5 per cent trypsin solution, no injurious effect was noted. Attempts to cultivate the cells in a growth-medium containing less than 20 per cent calf serum and to adapt the cells to a medium of which the serum component is of heterologous origin (human and horse serum) have failed consistently. Likewise, negative results were obtained when an attempt was made to store the cells by freezing by the methods described by Scherer and Hoogasian[4].

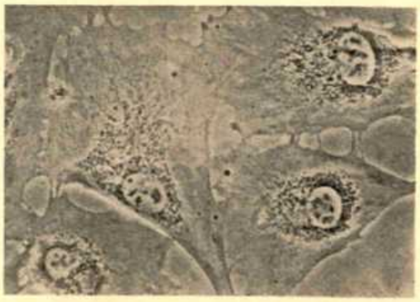

Fig. 1. Culture of lens cells of the calf (strain *T–5a*) from the twenty-fifth sub-culture ; phase-contrast. (× 560)

Poliovirus types 1, 2 and 3 did not produce degeneration of the *T–5a* cells and did not multiply in these cells either in primary culture or after passages. Adenovirus types 1–5, *7a* and 8 have been propagated serially in the cells through 5 passages with at least a 10^8-fold increase in infectivity and with reproduction of cytopathic changes similar to those in HeLa cells. The viruses caused a widespread cytopathic effect at the third to fifth day after primary inoculation. On subsequent passages, the changes were observed in a limited number of cells from the seventh to tenth day of incubation and they did not progress to complete destruction of the cultures. It is possible that the early cytopathic effect after primary inoculation is of a toxic nature, not necessarily associated with virus multiplication[5].

With the method described, we have succeeded in subcultivating cells from the lenses of two other calves (*T–5b* and *T–5c* cells). Three attempts to grow lens cells of the calf in continuous culture were unsuccessful. The *T–5b* and *T–5c* cells have been maintained through 18 subcultures for one year. No differences in morphology, growth, resistance to polioviruses and susceptibility to adenoviruses between *T–5a*, *T–5b* and *T–5c* cells were observed.

Effect of Controlled Lighting on Production Characters in the Fowl

King[1] recently reported that a combination of restricted lighting during rearing and increasing lighting during the laying season results in increased egg production in laying pullets. Morris and Fox[2] have suggested that sexual maturity is influenced by change of length of day rather than by the absolute amount of light the birds receive during rearing. They have already published interim results[3] of an experiment which supports this contention. Their experiment also shows that decreasing lighting during the rearing of pullets hatched in December delays maturity, increases weight of eggs, but does not lower total egg production during the first sixteen weeks of lay.

Similar work, to test experimental lighting techniques, was started last year on three farms; at Glinton, Northants, at Lucan, Eire, and at Stewarton, Scotland. At all locations there are two deep-litter cabins, one with windows and one without, which can be controlled for ventilation and temperature. Each cabin contains 120 small pens, 8 ft. × 6 ft.

To apply King's method in the field it is necessary to have windowless intensive rearing houses. At the present time few people in Britain have the required facilities and it would be useful to know if increasing lighting during laying alone would produce at least part of the increase in production reported by King. This type of treatment and King's complete treatment are being tested alongside conventional lighting treatments. The treatments applied at the three locations are summarized in Table 1. The birds were reared and housed under identical conditions at each location except for the lighting treatments. There is considerable uniformity of results from several strains within each location.

The results from Stewarton, after the birds have been in lay for five months, show that the attainment of peak production is delayed, and although percentage hen-housed egg production is now higher in treated birds there is little chance of them having a higher hen-housed egg production at the end of the laying season. They have dropped too far behind in the first three months of lay to be able to catch up on the controls. At Glinton (Table 2), where the birds were housed earlier, and have been in lay six months, the treatment delayed maturity (25 per cent production) by 36 days. This could be a combination of increased age at first egg and subsequent delay in attaining normal rate of lay. The results in other respects are similar to those from Stewarton. Apart from maturity and production there are some advantages for increasing lighting. First, there is evidence that mortality is reduced. Secondly, the coefficient of variation of egg production is reduced, which on the basis of some justifiable assumptions means that heritability estimates will be increased. This could lead to improved efficiency in selection experiments carried out under these conditions. Thirdly, during the first two or three months of lay there is evidence that egg weight is increased.

At Lucan, results (Table 3) show that restricted lighting during rearing, in combination with either increasing or constant lighting during laying, leads to all the advantages listed above. Further, though maturity (25 per cent production) is delayed about 6 days compared with birds reared on natural day-length, percentage hen-housed production rises more

Table 1. Treatments Applied

Location			0–23 weeks	Housed 23 weeks onwards		
Stewarton	Control	+	Natural day-length	14 hr. a day		
	Treated	–		6 hr. a day at housing increasing by 20 min. a week		
			0–16 weeks	Housed 16 weeks onwards		
Glinton	Control	+	natural day-length	14 hr. a day		
	Treated	–		6 hr. a day at housing increasing by 10 min. a week		
			0–4 weeks	4–12 weeks	12–20 weeks	Housed 20 weeks onward
Lucan	Control	+ +	24 hr. light a day	natural day-length	natural day-length	14 hr. a day
	Treated	– +			6 hr. light a day	
	Control	+ –	24 hr. light a day	natural day-length	natural day-length	6 hr. a day at housing increasing by 15 min. a week
	Treated	– –			6 hr. light a day

Egg weight, oz./doz. December	23·4	0·3	23·1

* Significant, $P < 0·05$. † Significant, $P < 0·01$.

sharply and reaches a higher peak. At the end of three months in lay, total egg production and percentage hen-housed production are higher in the birds which received restricted lighting.

If the hypothesis put forward by Morris and Fox[2] is correct, it is the change in length of day from one day old to housing, rather than restriction of light, which has brought about the consequent improved production. The pullets at Lucan, in fact, dropped from 24 hr. light a day during the first month to 6 hr. a day at housing. According to the formula given by Morris and Fox[3] this should delay maturity by 13 days compared with the control group. Their formula was calculated from data on Rhode Island Red × Light Sussex chickens and refers to age at first egg. The present observations refer to age at 25 per cent production, and, therefore, a comparison is not justifiable. However, the amount of delay may depend on whether the change in light during rearing is applied gradually, or, as in the experiment reported here, in a two-phase reduction.

Records from the birds at Glinton, Lucan and Stewarton will be collected for a ten-month laying season. The details and results of the experiments will then be published in full elsewhere, at a later date.

Sex Incidence of Vascular Lesions in Aging Rats in Relation to Previous Pregnancies

Wexler and Miller[1], in describing the production of severe arterial sclerosis in rats treated with corticotrophin, noted the greater susceptibility of their 1-year old breeding females to these lesions. We have found that during and between pregnancies, human uterine arteries undergo profound alterations, including 'reduplication' of internal elastic laminæ and massive intimal mucopolysaccharide accumulation. That alterations occur in pregnant women, not only in uterine but also in other arteries throughout the body, is suggested by the relationship which has been shown between pregnancy and aortic aneurysms or ruptures[2]. We therefore decided to investigate the spontaneous incidence of vascular injuries in breeding and non-breeding male and female stock rats in our colony. These animals consumed our standard diet, which permits normal growth, breeding performance and life-span.

The incidence of aortic and coronary mineralization in 81 untreated stock rats over the age of 500 days is shown in Table 1. It will be seen that these lesions were absent among male rats, occurring only in females ($P < 0·01$), and that among the latter the lesions were much more common in breeders than in non-breeders ($P < 0·02$). These discarded breeding females had all had 3–7 litters each.

Table 1. INCIDENCE OF BOTH AORTIC AND CORONARY MINERALIZATION IN STOCK RATS

(No. of rats with lesions/total rats in group)

Age group (days)	Male		Female	
	Non-breeders	Breeders	Non-breeders	Breeders
501–800	0/10	0/5	0/13	6/15
801–1,240	0/18	0/5	2/7	4/8
Total	0/28	0/10	2/20	10/23

Mineralization (calcium and/or iron 'coating') of the internal elastic membranes of smaller vessels, such as the coronary, mesenteric and uterine arteries, was common in these discarded breeding females, as was the deposition of iron in the basement membranes of the proximal convoluted tubules of the kidneys, and even in the depot fat cells. The aortæ (ascending, thoracic and abdominal) were, however, most severely affected in all instances (Figs. 1 and 2), and showed rigidity and calcification, and even cartilage and bone formation, together with the intimal and medial fibrosis, ectasia and heavy mucopolysaccharide accumulations mentioned by Wexler and Miller in their animals treated with corticotrophin. Calcification, with heavy mucopolysaccharide accumulations and cartilage formation was common in the papillary muscles of both ventricles, and this was associated with moderate fibrosis of the underlying myocardium. Increases in pericoronary reticulin were notable and, although gross infarcts were not found, patchy increases in myocardial reticulin were common. However, the coronary arteries themselves were not as seriously damaged in our untreated old breeding females as was apparently the case in Wexler and Miller's animals treated with corticotrophin; coronary thromboses were not seen by us, although the coronary vessels were unduly dilated, rigid and mineralized in our breeding females.

These lesions occurring spontaneously in breeding females were indistinguishable from those described

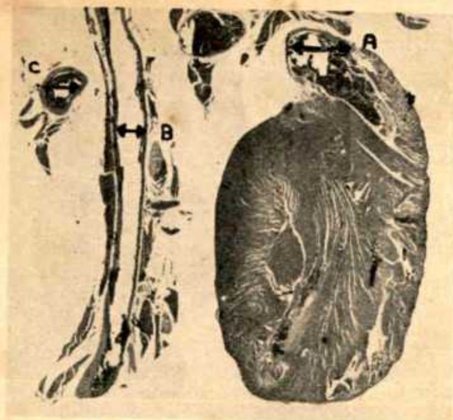

Fig. 1. Heart, ascending aorta (*A*) and thoracic aorta (longitudinal, *B*, and transverse section, *C*) to show cardiac size and aortic diameter (compare with Fig. 2). Stock non-breeding female 797 days old. Stained von Kossa. (× 3·6)

in healing arteries after short-term toxic doses of calciferol[3-5] as was the close association between mucopolysaccharide accumulations and mineral deposition and fibrosis. Selye[6] has shown that corticoids markedly increase the susceptibility of the coronary arteries in rats to similar acute traumata. The corticotrophin treatment applied by Wexler and Miller may thus have aggravated pre-existing cardiovascular lesions in their breeding females.

Closer attention to endocrine and other factors influencing the integrity of arterial walls during growth and under various physiological conditions, including pregnancy, certainly seems merited. Sex hormones have been shown to regulate circulating fibrin and fibrinolysins[7], anticoagulants, and even more powerful thrombolytic substances perhaps appearing in the circulation during pregnancy. The ovarian hormone relaxin, known to promote lysis of ligaments and even bone in œstrogen-primed animals, may affect arterial structure during pregnancy. The effects of endocrine glands, and of pregnancy in particular, in 'protecting' some arteries while promoting degeneration and subsequent intimal fibrosis, thrombosis or even rupture in others, thus merits experimental study and epidemiological surveys in man.

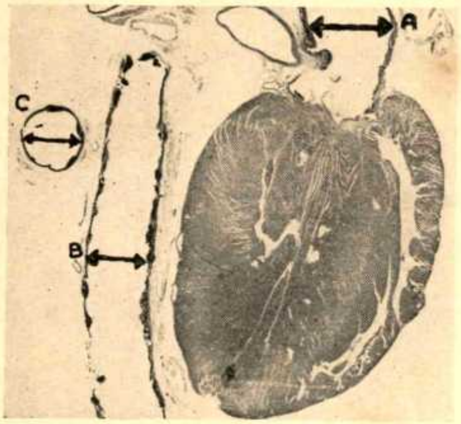

Fig. 2. Section similar to that in Fig. 1 but from 636-day-old female that had had five litters. Note enlarged heart, grossly dilated ascending aorta (*A*) and thoracic aorta (*B* and *C*). The black material in the aorta (*A*, *B* and *C*) is von Kossa-positive material (calcium); iron was also demonstrated in these areas. (× 3·6)

Amniotic Fluid and the Fœtal Lung

OF the problems associated with development of mammalian fœtal lungs, and with the changes they undergo just before and at birth, many are controversial, but Gairdner[1], in his careful review of the subject, states that "the weight of evidence supports the view that the fœtus normally inhales and absorbs liquor amnii".

During an investigation into the microscopic appearances of rat fœtal lungs following a variety of experimental procedures, I have been able to make an observation which not only throws considerable doubt on the hypothesis of Potter *et al.*[2] and Policard *et al.*[3] that the inhalation of amniotic fluid is a normal and necessary morphogenetic factor in the expansion of the alveolar spaces, but which also provides positive evidence of actual production of fluid by the fœtal lung, such as has occasionally been postulated.

Rat fœtuses were operated on *in utero* between the seventeenth and nineteenth days of gestation (the day of finding sperm in the vaginal smear being counted as day 1). The uterus was afterwards opened under pentothal anæsthesia in a warm saline bath some hours before the time for normal parturition on the twenty-second day. With minimal handling, and provided the placental circulation remained intact, both normal and experimental fœtuses invariably lay inert in the saline; in this state they were injected with either morphine sulphate or D-tubocurarine chloride in order to prevent the subsequent occurrence of gasping movements, which are capable in themselves of altering profoundly the appearances of intra-thoracic viscera. Fixation in Helly's fluid was followed by paraffin-embedding and serial-sectioning of the neck and thorax.

The aim of the first operation was to transect the trachea through an orientated stab-incision in the uterine wall. Survival-rates of operated fœtuses were as follows:

2-day survival	10 out of 17 operated
3-day survival	9 out of 14 operated
4-day survival	11 out of 36 operated

Preparation and study of the serial sections is now in progress. Operated animals show retardation in body-growth compared with normal controls, so that a twenty-second-day experimental fœtus usually corresponds approximately to a twenty-first-day control. Most of the 16 specimens so far studied in detail show little evidence of damage at the site of

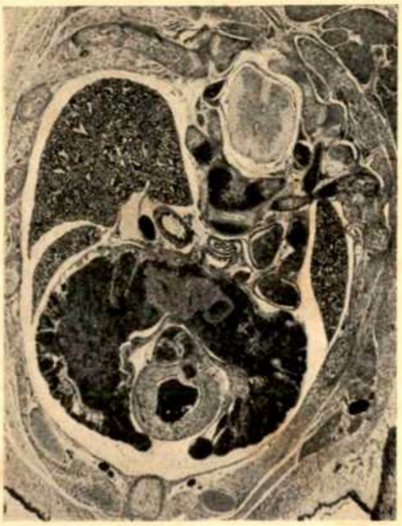

Fig. 1. (× 8)

incision. In some cases this may be because the transection was incomplete; but many of these specimens show marked accumulation of cells and cell-debris in the pharyngeal lumen: it is well known that fœtal tissues show remarkable powers of regeneration, especially when, as in these cases, the edges of the wound are left in close apposition.

Fig. 1 shows the thoracic viscera in transverse section at a standard level in such a fœtus on the twenty-second day, 4 days after the neck was incised. The microscopic appearances of the lungs are very similar to those in a normal twenty-first-day fœtus. Fig. 2 is a similar section from a litter-mate which had been operated on at the same time. In this specimen the margins of the incised trachea had failed to re-unite; in the serial sections there is a gap of 240μ between the blind ends of the proximal and distal portions of the trachea. The lungs were therefore isolated from the amniotic sac. Despite the small size of the animal and of its lungs, the latter are expanded to a degree greater than in a normal twenty-second-day fœtus. There is, in addition, a marked effusion into the pleural cavity, which is perhaps reasonably interpreted as the result of transudation from the overfilled alveolar spaces.

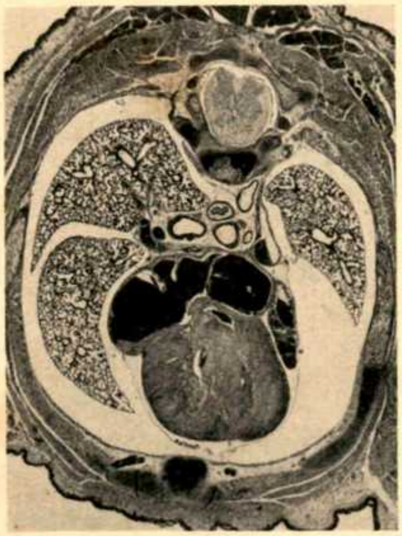

Fig. 2. (× 8)

It is concluded that the fœtal lung is capable of producing whatever fluid is necessary to fill the enlarging alveolar spaces. The fluid appears to be produced in excess, and this would favour the view of Whitehead *et al.*[4] that the lung is itself one of the sources of amniotic fluid. This conclusion is not necessarily true, however, and it is considered likely that any excess fluid would normally enter the pharynx and be swallowed by the fœtus.

This interpretation of experimental findings would appear to give a rational explanation for the similar appearances reported by Potter *et al.*[5] in a case of a human accessory lung without connexion to the trachea, and by Jost and Policard[6] in rabbit fœtuses previously subjected to decapitation. These authors were unable to account for their findings on the basis of their published views on the morphogenetic factors involved in normal fœtal lung-growth and expansion.

Work on this series, and other experiments on fœtal lungs, are still in progress.

Testing Populations of Beet Eelworm, *Heterodera schachtii* Schmidt, for Resistance-breaking Biotypes, using the Wild Beet (Beta *patellaris* Moq.) as Indicator

SOME species of wild beet, including *Beta patellaris*, are resistant to beet eelworm. The roots of *B. patellaris* are invaded by larvæ, a small proportion of which develop into mature males, but usually no mature females are produced[1].

Dunnett[2], Jones[3], Goffart[4] and Huijsman[5] found that some populations of the potato root eelworm, *H. rostochiensis* Woll., from various parts of Britain, Germany and Peru reproduce in the wild potato, *Solanum tuberosum* sub sp. *andigena*, which had been resistant to the populations previously tested. Populations of beet eelworm from various parts of England were therefore tested on *B. patellaris* to see whether any could be found able to produce cysts on this species.

Eight populations were tested from the following districts: Iffley, Oxon.; Soham, Cambs.; Waterbeach, Cambs.; Lakenheath, West Suffolk; Chatteris, Isle of Ely; Spalding, Lincs; Oxlode, Isle of Ely; Yeovil, Somerset. Plants of *B. patellaris* were grown singly in potting compost in 6-in. pots, plunged in gravel. Replication was three-fold and 4,000 hatched larvæ were added per pot.

Ten weeks after adding the larvæ, the tops were removed and the soil and roots air dried. Cysts were recovered by elutriating the soil[6] to ensure that all cysts present were detected.

A single cyst was found from one plant in each of the Spalding and Yeovil populations and two cysts from one plant in the Oxlode population. This is the first record of the development of females on *B. patellaris*.

Thus, although there is no evidence of resistance-breaking biotypes occurring on the same scale as found with *H. rostochiensis*, individual females able to develop on *B. patellaris* exist and their potential importance should be recognized. Further investigations are needed on the extent to which these biotypes can give rise to populations containing a larger proportion of such individuals. As one of the possibilities considered in breeding sugar beet resistant to beet eelworm is to introduce genes for resistance from *B. patellaris*, a situation favouring the multiplication of these biotypes might result from growing sugar beet × *B. patellaris* crosses in the field.

This work was carried out at the School of Agriculture, Cambridge, and financed by the Sugar Beet Research and Education Committee.

Persistence of Tomato Aucuba Mosaic Virus in Dried Leaf Tissue

IN December 1934, in order to keep in a convenient form some material of the strain of tomato aucuba mosaic virus with which I had been working at Rothamsted Experimental Station, some leaves of infected tomato plants were dried in air and put in an envelope.

After I came to this Department, some of this material was used from time to time for inoculating plants in connexion with the experiments being carried out here. The original virus has been transmitted from plant to plant by juice-inoculation for the past 24 years.

The envelope containing the original material (of December 11, 1934) was kept in a cupboard in the laboratory, and it was thought that it would be interesting to see what had happened to the infectivity of the virus after a period of desiccation of 24 years.

A small leaflet weighing 10 mgm. was crushed in a mortar and 10 ml. of water added and the whole thoroughly mixed. After 1 hr., an interval to allow of complete wetting of the dry material, about 0·1 ml. of liquid was rubbed on to each of 16 leaves of plants of *Nicotiana glutinosa*.

The control material was a fresh leaflet of tomato of approximately the same size as that selected for the first experiment. This was infected with the same strain of virus which through the years has been inoculated from tomato to tomato plant.

This material was again thoroughly macerated, mixed with 10 ml. water and left for 1 hr. at laboratory temperature. Similar amounts of liquid were inoculated by rubbing with a finger into each of 16 leaves of *N. glutinosa* plants. The results were as follows :

Material	Total number of lesions on 16 leaves
Dry material (Dec. 24, 1934)	2 + 1 (doubtful)
Control material (fresh)	652

The experiment was repeated using 200 mgm. of dried material in 10 ml. of water. Similar amounts were rubbed on to each of 14 leaves of *N. glutinosa* plants when it was found that, after an interval of 5 days, a total of 15 + 2 doubtful lesions had developed on the 14 leaves.

This same material was left for 24 hr. to allow further wetting of the dried material if this were necessary, and five lesions were found on fifteen leaves of *N. glutinosa* after inoculation and treatment similar to that noted above.

It appears, therefore, that while the activity of the tomato aucuba mosaic virus is very greatly reduced by desiccation and storage in a dry state for 24 years, there is still a little residual activity even after that period of time.

A Third Species of 'Pepper' in West Africa

Two workers on the peppers (*Capsicum*), Smith and Heiser[1], have recently discovered that among the peppers of Central and South America a new species of pepper, *Capsicum sinense* Jacq. had been present within the species *C. frutescens* L. This new species, which could not at first be detected when *C. frutescens* was itself separated from *C. annuum* L., is now recognizable by the 3–5 flowers at each node, the declinate pedicels, and the circular constriction at the base of the calyx in fruit, quite apart from the sterility barrier between it and the four other species of pepper in Central and South America, namely, *C. pubescens* R. and P., *C. annuum* L., *C. pendulum* Willd., and *C. frutescens* L.

This discovery calls for a verification in other parts of the world where the peppers flourish to see if this new species could be found there. West Africa is certainly one of the areas that are rich in peppers which form an important item of the local dish ; but only two species *C. annuum* L. and *C. frutescens* L. have been described[2]. For well over a year now, collection of local varieties of peppers have been made in West Africa with special reference to Ghana. More than sixty varieties have so far been cultivated and described (unreported), and the results show that the new species *C. sinense* is present also in West Africa. Two distinct varieties of this species have so far been distinguished, and these will be described separately elsewhere. Nothing has been found among the collection to answer to any of the other two species in Central and South America. This third species of pepper, *C. sinense*, in West Africa will have to be included in the "Flora of West Tropical Africa" now under revision.

Monday, April 20

British Society for the Philosophy of Science (in the Joint Staff Common Room, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. W. C. Salmon: "The Concept of Empirical Verifiability".

Society of Chemical Industry, Pesticides Group (at 14 Belgrave Square, London, S.W.1), at 5.30 p.m.—Annual General Meeting, followed by Dr. F. Call: "The Chemical Control of Nematodes in Soil".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 6 p.m.—Prof. J. B. Speakman: "Research in Wool". (First of three Cantor Lecturers. Further lectures on April 27 and May 4.)

Monday, April 20—Tuesday, April 21

Electrical Association for Women (in London)—Thirty-fourth Annual Conference. Theme: "Education in a Scientific Age". Speakers: The Rt. Hon. Reginald Maudling, M.P., The Countess Mountbatten of Burma, C.I., G.B.E., D.C.V.O., Ll.D., and Lady Bragg, M.A., J.P. Chairman: The Viscountess Kilmuir, D.B.E.

Monday, April 20 (at the Federation of British Industries. 21 Tothill Street, London, S.W.1), from 2 p.m. to 5 p.m.—Branch Officers' Session.

Tuesday, April 21 (at the Connaught Rooms, Great Queen Street, London, W.C.2), at 10.30 a.m.—Annual General Meeting.

Monday, April 20—Friday, April 24

Industrial Photographic and Television Exhibition and Conference (at the Royal Albert Hall, London).*

Tuesday, April 21

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, Westminster, London, S.W.1), at 9.45 a.m.—All Day Discussion on "The Structural Effects of Kinetic Heating".

Institution of Electrical Engineers, Measurement and Control Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Discussion on "The Problem of Maintenance of Electronic Equipment in the Process Industries", opened by Dr. G. Morris and Mr. N. T. C. McAffer.

Wednesday, April 22

Institute of Fuel (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Mr. T. C. Bailey: Presidential Address.*

British Institution of Radio Engineers (at the London School of Hygiene and Tropical Medicine, Keppel Street, Gower Street, London, W.C.1), at 6.30 p.m.—Dr. D. J. E. Ingram: "The Application of Magnetic Resonance to Solid State Electronics".

Women's Engineering Society, London Branch (at Hope House, 45 Great Peter Street, London, S.W.1), at 7 p.m.—Mr. A. B. McKenzie: "Development of the Gas Turbine Aero Engine".

Thursday, April 23

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Meeting for Election of Foreign Members, followed by Miss Elizabeth Rhodes and Prof. A. R. Ubbelohde, F.R.S.: "Melting and Crystal Structure. Effects of Thermal Transformations of Ionic Crystals on their Ultra-violet Absorption"; Mr. B. Szigeti: "Higher Order Terms in the Dielectric Constant of Ionic Crystals".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 5.15 p.m.—Mr. S. H. U. Bowie: "The Uranium and Thorium Resources of the Commonwealth".

Institution of Electrical Engineers (at Savoy Place, London, W.C.2), at 5.30 p.m.—Sir David Brunt, F.R.S.: "The Geophysical Year 1957–58" (Fiftieth Kelvin Lecture).

British Glaciological Society (at Bedford College, Regent's Park, London, N.W.1), at 6 p.m.—Annual General Meeting. Mr. C. W. M. Swithinbank: "Sea Ice in the North West Passage over the last 58 Years".

Royal Aeronautical Society (at the Institution of Mechanical Engineers, Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Mr. W. H. Stephens: "Earth Satellites".

Friday, April 24

Linnean Society of London (in the Lecture Theatre, British Museum (Natural History), Cromwell Road, South Kensington, London, S.W.7), from 10.30 a.m. until 6 p.m.—Meeting on "Comparative Studies in Ultrastructure". Speakers include Dr. George E. Palade, Dr. Sanford L. Palay, Dr. J. Hanson, Dr. H. E. Huxley, Dr. J. Lowry and Mr. Andrew F. Huxley, F.R.S.

Institution of Electrical Engineers, Radio and Telecommunication Section (at Savoy Place, London, W.C.2), at 5.30 p.m.—Mr. T. C. Macnamara and Mr. B. Marsden: "Engineering Aspects of Commercial Television Programme Presentation".

University of London (in the Anatomy Lecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. O. Heckmann (University of Hamburg): "Some Current Observing Programmes of the Hamburg Observatory". (First of three Special University Lectures in Astronomy. Further lectures on April 27 and 29.)*

Institution of Mechanical Engineers (at 1 Birdcage Walk, Westminster, London, S.W.1), at 6 p.m.—Annual Meeting.

Friday, April 24—Saturday, April 25

Royal Society of Medicine, Endocrinology Section and the Society for Endocrinology (with the participation of the Society for the Study of Fertility, the Medical Section of the British Diabetic Association, the London Thyroid Club, and the Endocrine Club, Glasgow, at the Royal Society of Medicine, 1 Wimpole Street, London, W.1)—Joint Endocrine Meeting.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturers (honours graduates in physics or chemistry) in Polymer Chemistry—The Registrar, Manchester College of Science and Technology, Manchester 1 (April 25).

Secretary (preferably with a professional qualification and experience in grant-aided work) of the Welsh Plant Breeding Station, to be responsible for the administration, accountancy and office organization—The Registrar, University College of Wales, Aberystwyth (April 25).

Lecturer, and a Lecturer (Grade B) in the Mathematics Department—The Secretary, Northampton College of Advanced Technology, St. John Street, London, E.C.1 (April 27).

Assistant Lecturer or Lecturer in the Department of Zoology—The Registrar, The University, Liverpool (April 28).

Senior Principal Scientific Officer (with a first- or second-class honours degree in chemistry, chemical engineering or physics, or equivalent, or high professional attainment, and practical experience in mineral dressing and/or hydrometallurgy) at Warren Spring Laboratory, D.S.I.R., Stevenage, Herts, to lead a section carrying out research on mineral processing—The Civil Service Commission, 17 North Audley Street, London, W.1, quoting Ref. S.4964/59 (April 28).

Assistant Lecturer in Physics—The Secretary and Registrar, University College of North Wales, Bangor, North Wales (April 30).

Assistant Lecturers or Lecturers in Civil or Mechanical Engineering—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (April 30).

Geologist (with an honours degree in geology requiring a four-year course at a recognized university, and preferably with previous experience) with the Government of Southern Rhodesia—The Secretary (R), Rhodesia House, 429 Strand, London, W.C.2 (April 30).

Lecturer in Physics—The Registrar, King's College (University of Durham), Newcastle-upon-Tyne (April 30).

Lecturer (with a special knowledge or experience of physical methods, and the ability to teach to honours standard, and to initiate and supervise research) in Pharmaceutical Chemistry—The Secretary-Treasurer, Royal College of Science and Technology, Glasgow (April 30).

Plant Physiologist or Botanist (with an honours degree in botany, and preferably postgraduate experience in plant physiology, biochemistry, or with herbicides) to evaluate new herbicides in greenhouse and pot culture studies and to determine their phytotoxic properties; and an Agronomist or Horticulturist (with an honours degree in agriculture or science with postgraduate training or research experience), to take charge of part of the field evaluation programme on new herbicides—Dr. E. K. Woodford, A.R.C. Unit of Experimental Agronomy, Department of Agriculture, Oxford (April 30).

Assistant Lecturer in Physics—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 1).

Assistant Lecturer or Lecturer (well qualified in systematic geography, and preferably first-hand knowledge of a region other than Western Europe) in Geography—The Assistant Registrar, The University, Edmund Street, Birmingham 3 (May 2).

Lecturer (with special qualifications and research experience in fruit growing) in Horticulture—The Registrar, Room 22 (O.R.B.), The University, Reading (May 2).

Lecturer in Physiology—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 4).

Assistant Lecturer (with special interests in crop production and the mechanization of crop production) in Agriculture—The Registrar, Wye College (University of London), near Ashford, Kent (May 5).

Chair of Physics—The Registrar, University College of North Staffordshire, Keele, Staffs (May 9).

Lecturer in the Department of Mathematical Physics—The Secretary, The University, Edinburgh (May 9).

Senior Lecturer and a Lecturer in the Department of Biochemistry—The Secretary, The University, Edinburgh (May 9).

Assistant Lecturer or Lecturer in Zoology with special reference to Entomology—The Secretary, Birkbeck College, Malet Street, London, W.C.1 (May 11).

Lecturer or Assistant Lecturer in Mathematics at the University College of the West Indies—The Secretary, Inter-University Council for Higher Education Overseas, 29 Woburn Square, London, W.C.1 (May 15).

Lecturer (preferably with interests in sedimentology or geophysical methods) in Geology at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (New Zealand, May 15).

Assistant Lecturer in Philosophy—The Assistant Registrar, The University, Edmund Street, Birmingham 3 (May 16).

Assistant Lecturer or Lecturer (with a special interest in some aspect of parasitology) in the Department of Agricultural and Forest Zoology—The Secretary and Registrar, University College of North Wales, Bangor (May 16).

Napier Chair of Astronomy—Joint Clerk to the University Court, College Gate, St. Andrews (May 16).

DEMONSTRATOR (with interests in palæontology, stratigraphy, sedimentary petrology or structural geology) IN GEOLOGY—Dr. I. D. Muir, Department of Mineralogy and Petrology, The University, Downing Place, Cambridge (May 23).

WRIGHT-FLEMING CHAIR OF IMMUNOLOGY in St. Mary's Hospital Medical School—The Academic Registrar, University of London, Senate House, London, W.C.1 (May 25).

CHAIR OF PHYSICS in the University of Hong Kong—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Hong Kong, May 30).

CHAIR OF PHARMACOLOGY—The Registrar, The University, Leeds 2 (June 1).

CHAIR OF AGRICULTURE in the University of Tasmania, Australia—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, June 15).

ASSISTANT FARM MANAGER (with at least a diploma in agriculture), to assist in running a medium-sized mechanized rice farm in Gambia, and to act as Manager when the Farm Manager is on leave—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/12/011.

ASSISTANT LECTURER (Grade B) IN GEOLOGY, to teach up to the standard of the B.Sc. (General) degree—The Clerk to the Governors, Northern Polytechnic, Holloway, London, N.7.

ASSISTANT PROFESSOR OR ASSOCIATE PROFESSOR OF MATHEMATICS—The President, Memorial University of Newfoundland, St. John's, Newfoundland, Canada, and The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1.

GEOLOGISTS (with a degree of a recognized university with either first- or upper second-class honours in geology, two years approved postgraduate experience, and preferably some specialization in mining geology) in the Geological Surveys Department, Federation of Malaya—The Recruitment and Personnel Division, Malaya House, 57 Trafalgar Square, London, W.C.2.

LECTURER (Grade II) IN THE DEPARTMENT OF ORGANIC CHEMISTRY—The Registrar, The University, Bristol 8.

RESEARCH ASSISTANTS (2) (with experience in aeronautical or electronic engineering or in physics) to undertake interesting theoretical and experimental work IN THE DEPARTMENT OF AERONAUTICAL ENGINEERING—The Secretary and Registrar, The University, Southampton.

SCIENTIFIC OFFICER IN THE VIROLOGY DEPARTMENT, for work on plant virus diseases—The Secretary, Scottish Horticultural Research Institute, Mylnefield, Invergowrie, by Dundee.

SENIOR BOTANIST (with a good honours degree in botany and considerable experience in crop breeding, preferably tropical crops) in Tanganyika, for production of improved varieties of crops for irrigation schemes with particular reference to dry season crops, and to lead a team of three breeders—The Director of Recruitment, Colonial Office, London, S.W.1, quoting BCD.63/8/024.

SENIOR PHYSICS MASTER—The Headmaster, School House, Cranbrook, Kent.

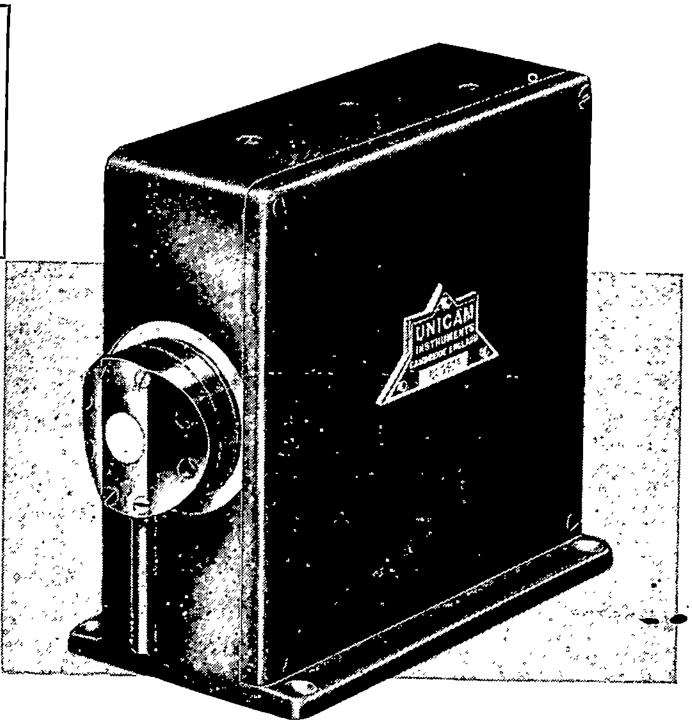
An INFRARED DETECTOR



sensitive from Visible to Microwaves

The operation of the Golay Detector is based upon the expansion of a gas of low thermal conductivity in contact with a non-selective heat absorbing membrane. The cell in which the gas (normally Xenon) is sealed has at one end a mirror membrane operating in a photoelectric amplifier system in such a way that the light intensity at the photocell varies directly with the gas expansion.

One of the major advantages of this system is a uniform sensitivity over a wide range of wavelengths. With suitable window material the Detector can be used to measure radiation intensities from visible light out to the microwave region. The adjoining table shows recommended window materials for specific wavelength regions.

The Detector can be delivered from stock with the following windows — KBr, Quartz, KRS-5, CsBr.

We shall be pleased to quote for alternative windows, for the Detector alone or for the full equipment including electronic and chopper units.

TABLE OF WINDOW MATERIALS

Material	Approximate useful wavelength limits
KBr	from visible to 26 μ — 27 μ.
CsBr	,, ,, ,, 35 μ — 40 μ.
CsI	,, ,, ,, 45 μ — 50 μ.
Quartz (0.25 mm thick)	,, ,, ,, 3.5 μ and from 45-50 μ to microwaves.
*Arsenic trisulphide	,, ,, ,, 10 μ.
*KRS-5	,, ,, ,, 35 μ.

*These two salts are non-hygroscopic but introduce some energy losses.

THE RELATION OF EDUCATION TO RESEARCH

IN opening a debate on education in the House of Commons on January 22, the Minister of Education, Mr. Geoffrey Lloyd, stressed the need for maintaining a balance between the different steps on the educational ladder. He said little about the grammar schools, apart from a passing tribute to the way they had adapted themselves to the scientific age. The secondary modern schools had no long traditions to help them, but Mr. Lloyd said that in spite of handicaps some of them had considerable achievements to their credit, and 75 per cent of all children in some schools remained on after the compulsory age. Referring to the supply of teachers, Mr. Lloyd said that he hoped to make the training colleges much more like university institutions than many of them had been in the past, and that if it was clear that the 50 per cent expansion proposed by the Government was not enough, the Government would re-consider the expansion programme. There was no reference specifically to science teaching, but it has been stated that £2 million a year is being spent on laboratory buildings at maintained secondary schools, though without much more help the position at this critical point may well deteriorate rather than improve, as Dr. K. Hutton's recent address at the North of England Education Conference indicated.

In replying on the debate, the Parliamentary Secretary to the Ministry of Education, Sir Edward Boyle, pointed out that while the number of children in primary schools had fallen by 150,000–200,000 in the past two years, 200,000 extra places have been provided. Primary schools themselves will benefit in three ways from the Government's proposals for secondary education. Removal of senior children from all-age schools will leave more space for the younger children; resources are to be found during the five-year period both for building new primary schools in new housing areas and for completely replacing some of the worst primary school buildings; and a substantial part of the resources available for minor projects (costing less than £20,000) will be devoted to improving primary schools. As regards the reduction of all classes, junior and senior, to a maximum of thirty, Sir Edward Boyle pointed out that this would require a further 110,000 teachers over and above the present 260,000, and an increase of this scale is impracticable during the next few years. Finally, he repeated the assurance in the White Paper that there would be no attempt at a uniform pattern of secondary education. Whatever the best solution may be in new housing areas or sparsely populated areas, in Mr. Lloyd's view it would be wrong so to organize secondary education in the big cities of Britain as to leave parents no freedom of choice and to uproot good established schools, especially grammar schools, which are already doing first-class work.

Almost the only reference to expenditure in the debate was that of Mr. J. C. Jennings, who pointed out that the Government is already committed to £300 million for school building in the next five years, to £15 million for training colleges, £100 million for technological education and to £95 million between 1957 and 1963 for universities, and it is expected that the total figure of approaching £800 million for the present year would reach £1,000 million by 1963–65. Since then, the Minister of Education has given further details of the training college programme, which will include about seventy projects and is inspired by five principles: a considerable increase in the average size of the colleges, so that 40 per cent will have more than 400 places and provide 60 per cent of the total intake; the colleges will be made much more like university institutions than in the past; there will be a sensible distribution of the new places throughout England and Wales, with particular attention to areas with a serious shortage of teachers; special emphasis is being given to the training of more teachers of science and mathematics, and of certain other practical subjects; and the number of colleges catering for both men and women will be more than doubled.

The prospective supply of staff was one factor which has led the Minister to limit the current programme to 12,000 places, but Mr. Lloyd has already told the House of Commons that he is prepared to extend the programme if it appears that this 50 per cent expansion is insufficient, though he indicated that it would probably be wiser to extend the programme for a year or two after 1962 than to attempt more before then. On February 9 the Chancellor of the Exchequer announced that he proposed to ask Parliament to increase by £2,550,000 the recurrent grant of £34,350,000 already proposed for the universities for 1959–60, and to increase those for 1960–61 (£36,750,000) and 1961–62 (£39,500,000) by £2,660,000 and £2,720,000, respectively. The Department of Scientific and Industrial Research, moreover, is now prepared occasionally to recommend grants for special researches for periods up to seven years initially, instead of five years, as hitherto, and its new policy may well tend to increase the total allocations to the universities, even if the actual awards are earmarked for research. Furthermore, some of the evidence submitted to the Anderson Committee on Grants to Students, notably the recommendations from the National Union of Students that awards should be made without reference to parental income, would, if accepted, further increase the national expenditure on university education by perhaps £1·5 million a year.

Apart from its failure to consider expenditure and the critical issue of science teaching, the debate was disappointing in that secondary education was not properly considered either in relation to the educational system of Britain as a whole or, apart from the stress laid by both Ministers on the need to consider the individual boy or girl, to the demand for talent. It should be almost a corollary of providing equality of opportunity and freedom for the gifted individual student to develop his or her ability to the full that there should be some relation between the scale of public education and the opportunities which the nation can provide for trained man-power. Notably the debate was characterized by lack of appreciation of the interdependence of the various levels of education, and of the way in which expenditure at one stage might limit expenditure at others, quite apart from considerations of available teachers or other resources.

Such considerations should determine Britain's expenditure on university and technical education, and the form which university expansion should take. Dr. B. V. Bowden has urged that we need more and bigger schools and more and bigger universities if we are to develop higher education sufficiently to meet Britain's needs as a great manufacturing and trading country. He has pointed out, too, that industry has a large part to play in developing and financing this expansion, and that unless industry prepares now, the larger number of graduates in technology and engineering who will be leaving the universities and colleges of technology in a few years time will be unable to complete their education. Moreover, such co-operation is not entirely one-sided. In Dr. Bowden's view, British universities do not make sufficient use of the facilities for research which are available in industry or through the Department of Scientific and Industrial Research.

This is a particular aspect of the organization in Britain for research, and it is one to which due attention should be paid in considering the functions of that Department's own research stations and of the research associations. There are dangers in the isolation of such institutions from academic life, as there are in the isolation of the universities themselves; and the repercussions between research and teaching are also complex and merit more attention. Apart from the question whether students in general should be encouraged to take up research unless they contemplate such a career and evince aptitude for research, there are questions as to the bearing of research on effective teaching, particularly in relation to facilities and the technical assistance available to the teacher who is also occupied in research.

All this is related, too, to the question of the size and distribution of universities in Britain as well as their number. The discussion on the size of universities and university departments at the Conference of the Universities of the United Kingdom last December showed that we are as yet far from agreement as to the right solution of the problem of university expansion. Sir Patrick Linstead argued cogently that it is important at such a time of rapid expansion to consolidate existing institutions rather than found new ones, and the argument that proper weight must be given to the efficient size of departments and of faculties has the more force when it is essential to ensure the maximum use of available resources in finance and in teaching staff. Sir Patrick considers that a university department in subjects which are rapidly expanding and sub-dividing should have at least 150–200 students, and while he does not favour expansion of non-collegiate universities beyond about 4,500 students, he thinks that an arts faculty should contain at least 1,000, a science faculty 600 and a faculty of applied science 800 students.

Sir Patrick believes that the principles he puts forward, if applied to the existing universities of Britain, including the projected University of Sussex, would provide sufficient space for all but 5,000 of 124,000 students visualized by 1965, and that this deficiency could be met by founding one new university, for example, at Norwich, and developing three or four new faculties of technology at existing universities. Prof. E. Devons thinks that the problem of size requires rather more study, and like Lord Simon in a recent article in the *Universities Quarterly*, leans towards a comparative study of university administration and organization, without, however, suggesting that a Royal Commission is needed. Lord Simon, it is true, suggested that numerous other problems, such as the factors determining university expansion, the allocation and control of grants by the University Grants Committee, the abolition of fees, the relations between research and teaching, merit independent examination.

Dr. R. Pedley, however, at the Universities Conference, favoured the establishment of several new universities largely because of the unequal contribution which a university can make to the quality of regional culture, and for this reason visualized new universities on Teeside, in mid-Lancashire, Coventry and the Home Counties. He also thinks that a further 46,000 places will be required by 1965, even if only 5 per cent of the pupils in comprehensive schools qualify for university entrance. He does not believe, moreover, that a scarcity of university teachers of high calibre is a sufficient reason for denying university education to those who might profit by it, and, while urging the desirability of a graduate teaching profession, he is prepared to accept a higher ratio of students to staff until 1970 than at present, provided those students had learned in school how to study and how to organize their lives.

As might have been expected, the Universities Conference showed awareness of the need for the educational system to be balanced; but that is very far from being fully recognized by Parliament as yet, nor has the Government taken any apparent steps to secure such a balance, even within whatever limits of expenditure it is prepared to propose. The Earl of Dundee, in replying for the Government on a notable debate on the youth services in the House of Lords on February 4, did indeed stress the importance of the contribution which the varied institutions of further education, including many voluntary bodies, have to make to the preservation of the permanent values in human character on which the stability of our way of life so largely depends. Unless such virtues as discipline and unselfishness, patriotism and loyalty and true religion are actively fostered, the best literary and scientific education in the world will not preserve the soul of a great country, and scientific progress and material achievement may come to naught.

The problems of educational expansion are indeed complex and varied, but it is not difficult to discern the correct priorities at any moment, though those priorities will themselves change from time to time. What is of first importance at present is that policy should be determined not by political doctrine but by educational needs and experience. There is indeed much that is common ground between the major political parties, and ample room for experiment without disturbing the functioning of existing institutions by introducing political uncertainty. An all-party approach would likewise assist to make available the greater resources Britain clearly needs to allocate to education, and to secure the most effective distribution of those resources. The task at any level is too immense for us to look for success except by co-operation on a much greater scale than in the past, and to promote the appropriate atmosphere of co-operation is a first duty of every responsible citizen. In such an atmosphere it will be the easier to resolve wisely the inevitable clashes between sectional and national views, and to secure the agreement to allocate special effort or resources at whatever point, such as the training of teachers of science, the improvement of school laboratories, or the expansion of technical colleges, that may at the moment be most needed, or to take the less spectacular measures designed to avoid waste of talent and resources and ensure that the country gets full value from its mounting expenditure on education.

SOCIAL POLICIES AND SOCIAL CHANGE

Essays on 'The Welfare State'

By Prof. Richard M. Titmuss. Pp. 232. (London: George Allen and Unwin, Ltd., 1958.) 20*s*. net.

In the course of the first of this series of essays Prof. R. M. Titmuss comments that it was characteristic of Prof. R. H. Tawney that he constantly reminded his students that "the most important thing about a man is what he takes for granted". It is equally characteristic of Prof. Titmuss that he makes it impossible for his readers to go on taking for granted those presuppositions about social policies and institutions which are all too easily accepted and acted upon by so many people. Whether he is writing about the differing provisions made for income maintenance in old age, about the position of women in modern society, about medical care under the National Health Service, he is careful to examine the relevant data afresh, often bringing to light new or little-known information in the process. The resultant discussions are always stimulating and illuminating. Sometimes they are disconcertingly so, and whether we accept his final conclusions or no, Prof. Titmuss certainly challenges us to think again about the subjects under discussion.

The topics covered in this collection of essays are varied and at first sight disparate, but, as is pointed out on the fly-leaf, two broad themes unite them—changes in social structure and developments in social policy, and it is one of the chief merits of Prof. Titmuss's whole approach that he relates the two processes in a way seldom attempted either by academic sociologists or students and practitioners of social administration. For example, pension policies are considered in the context of population change, and current problems and practices of the National Health Service are related both to the scientific revolution in medicine which began in the late 1930's and to the psychological and social factors affecting the individual's and society's attitude towards health, disease and medical care. The relationship between institutions and policies is similarly emphasized in those essays which take as their starting point a social institution. For example, in the essay on "Industrialization and the Family", Prof. Titmuss shows that, on one hand, problems of human relations in industry cannot be solved within industry itself, and on the other, that the family does not function in a social vacuum. Rather is it profoundly affected by the forces of industrialization, and in this context we can see the social services in "a variety of stabilizing, preventive and protective roles".

Not only do these essays differ in subject-matter, they are based on lectures given at different times and places to audiences of different background and outlook. The first was delivered in 1951 at the London School of Economics, whereas those on the National Health Service were addressed to an American audience at Yale in 1957. This does not destroy the underlying unity, but it does mean that each essay is more or less self-contained, and the book as a whole, valuable and stimulating as it is, is but a foreshadowing of what Prof. Titmuss might achieve had he the leisure and opportunity to produce a major work dealing with the broader aspects of social policy, to the study of which he brings such depth of insight and breadth of vision. M. P. Hall

THE QUINTESSENCE OF PARACELSUS

Paracelsus

An Introduction to Philosophical Medicine in the Era of the Renaissance. By Walter Pagel. Pp. xii+368. (Basel and New York: S. Karger, 1958.) 70 Swiss francs.

Probably no other figure in the history of medicine and science offers greater difficulties to our understanding than Paracelsus. Probably none of the numerous books on Paracelsus is more helpful in forming an objective and clear appreciation of Paracelsus than this new book by Dr. Pagel.

The author achieves this goal by concentrating on the philosophy of Paracelsus, which sees cosmology, theology, natural philosophy and medicine in the light of analogies and correspondences between the macrocosm and the microcosm, man. Naturalism is with Paracelsus the search for divine signs. He is, therefore, with all his protoscientific ideas and achievements, not a scientist in the modern sense.

The author analyses in detail the Paracelsian concepts of 'experience', astrology, time, the elements, the famous three principles (sulphur, salt, mercury) and quintessence. There is a certain contradiction between the microcosmic dilution of man and the idea of specificity, equally important to Paracelsus, and embodied in the archeus or archei. 'Imagination' provides man with great spiritual power.

The medicine of Paracelsus is but an application of these general ideas. Paracelsus regarded diseases as specific fruits of the human body in the same fashion in which the metals were specific fruits of the earth. In spite of his chemical pathology Paracelsus tends toward localizing disease on his firmament of organs. But disease is essentially the result of an extraneous force, an invader, a seed. This specific agent has to be treated etiologically by specific remedies (ancient therapy was non-specific), which are often chemicals. Paracelsus paid particular attention to diseases due to tartar, fought the doctrine of catarrh, and developed a new theory of plague. He began to replace medieval uroscopy by quantitative and chemical analysis of urine. The author gives a long list of his practical achievements in medicine, always combined with wild speculations (antiseptic principles, syphilis, mercury as a diuretic, hydrotelluric theory of goitre, balneology, miners' diseases).

Dr. Pagel then analyses with wonderful scholarship and great penetration the sources of Paracelsus: gnosticism, the Cabbala, neoplatonism, Avicebron, Ramon, Lull, Arnuld of Villanova, the alchemists John de Rupescissa, Reuchlin, and Agrippa of Nettesheym. He also discusses in detail Paracelsus's great critic, Erastus, and his moderate defender, Daniel Sennert.

Paracelsus was, according to the author, an able chemist, and his medicine has elements of what was to become modern medicine. But his chemistry and his medicine were but parts of his symbolistic, decidedly unscientific cosmology and philosophy. He produced scientific results from a non-scientific world of motives and thoughts. He offered little which in principle cannot be found with his medieval predecessors, but he integrated all these elements into a new doctrine of medicine and natural philosophy. Without Paracelsus there would have been no iatrochemistry. He was a 'Magus' who forged a new synthesis from personal experience.

I do not hesitate to rate this book as the most valuable in the whole extensive literature on Paracelsus from the point of documentation as well as judgment. It is a high point in the author's long and distinguished career as a medical historian, which began with his work on van Helmont in the late 1920's and continued the great accomplishments of his father, Julius Pagel. It avoids equally the nebulous enthusiasm and the embittered hostility encountered so often in writings on Paracelsus. Dr. Pagel unites an unqualified attachment to modern science with a profound feeling for and understanding of mystic and magic philosophy. This rare combination enables him to be just and to give us the quintessence of Paracelsus.

Erwin H. Ackerknecht

MEDICINE IN INDUSTRY

Industrial Hygiene and Toxicology

Edited by Frank A. Patty. Vol. 1: General Principles. Second, revised edition. Pp. xxvii+830. (New York: Interscience Publishers, Inc.; London: Interscience Publishers, Ltd., 1958.) 17.50 dollars.

The first edition of Patty's "Industrial Hygiene and Toxicology" was published in 1948 in two volumes. The second edition is to be in three volumes, of which the first is now ready. It is not possible to assess the whole work until it finally appears, but, according to the preface to the second edition, much of the new matter has been placed in the first volume. The main changes are to be found in the treatment of such subjects as noise, heat, ionizing radiations, human engineering and industrial safety, sanitation, air pollution and illumination. Additional chapters on air conditioning, air cleaning, and heat control in the hot industries are included, as well as separate chapters on illumination and industrial sanitation. Dr. O. A. Sander contributes a revised chapter on the pulmonary dust diseases, Dr. L. Schwartz and Dr. Carey McCord bring up to date their chapters on the industrial dermatoses and the visible marks of occupation, respectively. The editor, Mr. Frank Patty, is responsible for four chapters on such subjects as the industrial hygiene survey, the mode of entry and action of toxic materials and sampling and analysis of atmospheric contaminants, in addition to his introductory chapter on industrial hygiene. This chapter calls for some comment, because Mr. Patty seems to have the idea that analyses of the contaminants of factory atmospheres did not begin in Great Britain until the formation of the Occupational Hygiene Society in April 1953, and that until that date medical control and not engineering control of health risks had been used. The fact is that both methods of control have been used in Great Britain for many years. Nevertheless, industrial or occupational hygiene is a rapidly developing subject, and the industrial health engineer is a new importation from the United States.

The first edition of Mr. Patty's book was an ambitious, but rather uneven, attempt to bring all the facets of industrial hygiene within the same close and curtilage. It showed that the industrial health engineer has the freedom of engineering, chemistry, physics, biology, physiology and medicine, and speaks with equal authority on all of them. In this age of super-specialization, the health engineer is therefore a refreshing phenomenon. The engineer who writes with authority on clinical medicine and hæmatology, without the benefit of a medical training, is to be congratulated on his courage. No doctor with experience of industry has yet been bold enough to write and edit a book on engineering. But that state of affairs may yet arise, because the industrial doctor in Britain is obliged to make himself familiar with the intimate details of factory processes, and with the estimations of contaminants in the atmosphere and its engineering control. In the United States it is rare for the plant doctor to deal with such matters, which are left to the health engineer, or industrial hygienist. It seems to us in Britain that the American version of the health engineer is probably taking on too much responsibility for health matters. No doubt in the course of time the industrial hygienist will find his proper place. Mr. Patty himself shows that the position in the States is being slowly modified. "Industrial hygiene," he writes, "has successfully withstood abortive efforts at absorption by both safety engineering and medicine. It borders on each of those fields, but differs in technique from both, and one of its primary functions is to get these two groups to work hand in hand." He has little doubt that regular and more frequent medical examinations are a desirable way of discovering dangerous exposures, especially in the absence of competent industrial hygiene engineering and control; and he affirms that when the two methods are properly co-ordinated, the most dependable safeguard against harmful exposures is provided. He has yet to reach the logical conclusion that the major responsibility for health matters in industry rests with the medical profession, assisted, as it should be, by capable and knowledgeable industrial hygienists.

A. I. G. McLaughlin

RADIOACTIVE ISOTOPES IN BIOCHEMISTRY

Radioaktive Isotope in der Biochemie

Von Prof. Engelbert Broda. (Einzeldarstellungen aus dem Gesamtgebiet der Biochemie, Neue Folge, Band 3.) Pp. viii+326. (Wien: Verlag Franz Deuticke, 1958.) 294 schillings.

FEW techniques have had a more widespread or profound influence on modern biochemistry than the application of isotopes. Although the first experiments were carried out by Hevesy more than thirty-five years ago, many isotopes have been available for a much shorter time and the use of isotopes in biochemical research has increased remarkably in the past fifteen years, as shown in an instructive table in this book. During the same period there have been considerable improvements in the instruments required for radioactive tracer work and there is thus sufficient scope for a new book, despite the existence of several well-established works.

Prof. E. Broda of the University of Vienna has written a book which is intended to serve both as an introduction to the methods used in work with radioactive isotopes and as an outline of the major biochemical problems in which isotopes have been particularly useful. Thus, the first eight chapters of the book deal with the production of isotopes, the synthesis and biosynthesis of labelled compounds, the hazards involved in work with radioactive substances, precautionary and protective measures, and the measurement of radioactivity. The treatment is concise, easily intelligible and useful for those interested mainly in acquiring sufficient knowledge for applying radioisotopes to their own problems.

The next two chapters deal with analytical applications, such as the isotope dilution method, and with metabolic pools and turnover. Finally, there are five chapters on main problems (phosphorylation, photosynthesis, carbon dioxide fixation, the metabolism of carbohydrate, fat, protein and nucleic acids, the citric acid cycle, purine and pyrimidine biosynthesis) and one on special problems of metabolism (immunological problems, the biosynthesis of porphyrins, cholesterol and lignin). This last chapter also contains a very brief (five pages) and somewhat inadequate section on the metabolism of biologically active compounds such as vitamins, drugs and carcinogens.

Although the book has been deliberately restricted to radioactive isotopes, stable isotopes are fortunately not completely neglected. For example, double intramolecular labelling with deuterium and carbon-14 is briefly mentioned (p. 31) and the importance of the stable isotope nitrogen-15 is indicated on pp. 223–29. The only notable omission is the application of isotopes, both stable and radioactive, to studies of the mechanism of enzymic reactions.

The book is well produced and there are very few errors. In some cases, however, there are slightly misleading statements, as for example on p. 16 where it is suggested that oxygen exchanges between the two positions of a carboxyl group, which are, of course, equivalent because of the symmetry of the carboxylic anion. It is a little surprising to read that the basic outline of protein synthesis is still completely unknown (p. 216) and that carboxyl activation of amino-acids is regarded as merely probable (p. 221). Also on p. 221 there is some confusion between transpeptidation and *de novo* peptide bond synthesis. But these are perhaps only minor matters in a book primarily concerned with isotopes.

The literature references are remarkably up to date, many of them being to publications which appeared in 1957. It is to be hoped that an English translation of this useful book will be forthcoming.

H. R. V. ARNSTEIN

NUCLEAR ENGINEERING MONOGRAPHS

Nuclear Engineering Monographs

No. 1, Elementary Nuclear Physics. By W. K. Mansfield. Pp. viii+60. 10*s*. 6*d*. net. No. 2, Nuclear Reactor Theory. By J. J. Syrett. Pp. viii+80. 12*s*. 6*d*. net. No. 3, Reactor Heat Transfer. By W. B. Hall. Pp. viii+68. 10*s*. 6*d*. net. No. 4, Nuclear Reactor Shielding. By J. R. Harrison. Pp. viii+68. 10*s*. 6*d*. net. No. 5, Nuclear Reactor Control and Instrumentation. By J. H. Bowen and E. F. O. Masters. Pp. x+78. 12*s*. 6*d*. net. No. 6, Steam Cycles for Nuclear Power Plant. By W. R. Wootton. Pp. vii+66. 10*s*. 6*d*. net. (London: Temple Press, Ltd., 1958.)

THE first three books in this excellent series were published about a year ago, and the final three quite recently. The six fall into two classes: Nos. 1, 2 and 4 provide summaries of matter which is readily available in greater detail elsewhere; and Nos. 3, 5 and 6 provide summaries of matter either not previously published or else dispersed rather widely.

There is general agreement that nuclear engineering is more appropriately studied at postgraduate level. However, nuclear physics is a useful subject for inclusion in the final year of undergraduate syllabuses and many universities provide this type of course. Advanced physics text-books are inappropriate at this stage, but the first monograph dealing with the modern concept of the atom, radioactivity, nuclear reactions and the detection of nuclear radiations is at a suitable level.

A physicist or engineer dealing in great detail with reactor physics might prefer to by-pass the monograph on reactor theory and work directly on the more comprehensive standard texts. The design of a reactor core is essentially a compromise of many conflicting criteria and a large number of engineering designers need to know the form in which the physicist does his calculations and the probable significance of changes in core geometry. Mr. Syrett's concisely written book outlines the framework of this important subject, and the text is sufficiently brief to assist in absorbing the principles. Even when reading the more detailed text-books it is useful to have the monograph to hand to show the way through what might otherwise appear a very complex analysis. The monograph deals with the slowing down and diffusion of neutrons, lattice calculations and the calculation of critical size. The chapter on "Reactor Operation at Power" is a particularly good introduction to the subject.

The third monograph in the first class mentioned above is that on reactor shielding. The author introduces his book by saying that a great deal of experimental and theoretical work is being undertaken on the subject of shielding and that 'art' is being replaced by science. Existing texts on the subject are bulky and contain masses of data. The monograph is welcomed as providing a guide to the important considerations; it is divided into three main sections, the first dealing with gamma-rays and their attenuation, the second with the neutron physics relevant to shield design, and the third with practical shield design.

The first monograph in the second group is that on heat transfer. Little had been published on reactor core heat transfer in Britain prior to the 1958 Geneva conference. This book is divided into two sections, and most experimenters will be sympathetic in the method of splitting as between fundamental work and work of immediate practical application. The heat-transfer specialist in nuclear power has the twin function of testing fuel-element cans under simulated reactor conditions to give exact design figures, and of carrying out inspired research work to provide the answers for subsequent stages in reactor development. The chapter on fundamentals sets out in a concise form the analytical approach, and describes the various analogies between heat and momentum transfer. The second chapter derives the usual design formulæ for channel heat transfer and pressure drop and ends with a comparison of gaseous coolants and a worked example. The final chapter considers such topics as liquid-metal heat transfer, fin efficiency and a comparison between liquid and gaseous coolants.

The monograph on reactor control and instrumentation is welcomed as providing a basis for later, more detailed, texts on these subjects. The incident at Windscale emphasized the need for comprehensive instrumentation in present reactor designs, and the lecture by Sir John Cockcroft in Tokyo last November mentioned two phenomena, positive moderator temperature coefficient and disturbances in the power distribution in a reactor due to local changes in xenon poisoning, with which the designers of the current stations have to cope. The present monograph must suffice until nearer the commissioning times of the Central Electricity Generating Board and the South of Scotland Electricity Board stations. The subject of control is a complex one ranging from neutron kinetics to the thermal response of a steam-raising unit. The monograph deals with neutron kinetics conventionally. The following chapter on temperature-stabilized reactors is important. As the authors mention, this type of analysis would in practice be carried out using an analogue computor. The numerical and graphical methods described do, however, show the trends. In later editions of these monographs, the final chapter of this book on instrumentation might well prove the basis for a seventh monograph, and then include health physics instrumentation.

The monograph on steam cycles consists of two main sections, one dealing with graphite-moderated, gas-cooled reactors, and the other with water-cooled, water-moderated reactors. It is worth remembering that the dual pressure cycle for the former type of reactor was first suggested in 1948. Since that time considerable effort has been expended in dealing with the number of variables involved. The essential tools are given in the appendixes, but the work involved is laborious. It is to be regretted that some co-operative effort was not made years ago to publish comprehensive graphs of the form given in this book. The section on water-cooled reactors deals with both pressurized-water and boiling-water types, and includes a short section on the use of a coal-, oil- or gas-fired superheater.

The editor of this series is to be congratulated in providing a number of stimulating monographs.

R. Vaux

LOW TEMPERATURES

Low Temperature Physics and Chemistry

Proceedings of the Fifth International Conference on Low Temperature Physics and Chemistry held at the University of Wisconsin, Madison, Wisconsin, August 26–31, 1957. Edited by Joseph R. Dillinger. Pp. xxv + 676. (Madison, Wis.: University of Wisconsin Press, 1958.) 6 dollars.

Kältetechnik

Von Prof. Matts Bäckström. Zweite überarbeitete Auflage. Bearbeitet und ins Deutsche übertragen von Dr.-Ing. Eduard Emblik. Pp. xvi + 656. (Karlsruhe: Verlag G. Braun; London: K. G. Heyden and Co., Ltd., 1957.) 56 D.M.; 98*s*.

INTERNATIONAL conferences on the progress of low-temperature physics are held bi-annually. The book, published by the University of Wisconsin Press and edited by Dr. J. R. Dillinger, contains the reports of such a conference held in Madison, Wisconsin, in 1957. The reports were furnished by the speakers and, since it was originally intended to bring out a simple stencilled version quickly, the figures are in many cases rough diagrams. Altogether, more than two hundred reports from all branches of low-temperature research are presented, and it is, of course, ~~quite~~ impossible to give even a rough survey of the contents.

The previous low-temperature conference was held in Paris in 1955 and much of the work reported in Wisconsin is necessarily a continuation of research discussed at the Paris meeting. There were a number of new developments in the field of nuclear orientation. The most outstanding of these are the experiments on the anisotropy of beta emission which provided the proof of the non-conservation of parity postulated by Yang and Lee. Another paper reported the successful orientation of nuclei by the method suggested by Pound in which use is made of the coupling between the lattice electric field and the nuclear quadrupole moment. It is unfortunate that a special lecture by Dr. N. Kurti on nuclear cooling has been published separately and is not included in the book.

An important advance in the theory of superconductivity was made by Bardeen, Cooper and Schrieffer, and a number of papers were read on experimental confirmations of this work. In particular the work on absorption of radiation at wavelengths between 0·1 and 1 mm. and that on the change of ultrasonic attenuation when a metal becomes superconductive deserve mention. The first reports were also submitted on a practical application of superconductivity which may lead to far-reaching developments. This is the use of superconductive switching elements in computors and in memory devices.

A certain amount of new information on liquid helium and especially on the behaviour of the light isotope is noted. Interesting advances have been made in the cryogenic use of the latter and it was regretted that Soviet scientists, who have done much work in this field, had not been able to attend.

Dr. Bäckström's book is a translation into German of the Swedish original. It deals with a great many aspects of refrigeration technique, mainly in the range of interest for food storage. It is not a text-book but rather an information manual which will be of interest to those specializing in this field.

K. Mendelssohn

The Measurement of Soil Properties in the Triaxial Test

By Dr. Alan W. Bishop and D. J. Henkel. Pp. viii+190. (London: Edward Arnold (Publishers), Ltd., 1957.) 70*s*. net.

THE Department of Soil Mechanics in the Imperial College of Science and Technology, London, has a standing in teaching and research second to none among schools of soil mechanics, and its students are drawn from all over the world. This is at once an assurance that the training given is valued and widely disseminated. Dr. A. W. Bishop is reader and Mr. D. J. Henkel lecturer in this Department, and to read their book is to be taken with firm direction through a course of instruction in their own laboratory; to be taught sufficient about the application of triaxial tests to appreciate their significance, and much of the art of making the tests and keeping them meaningful. The authors tell us they do not intend their book as a manual, presumably because they have limited themselves to describing the methods and theories which have been developed at the Imperial College, but though it may not be a manual, there is no doubt that for many readers it will form an adequate text-book. Its four parts deal with the [redacted] application of test data; the detailed construction of apparatus; the standard tests for which the apparatus is intended, and various special tests for which it may be used.

The ground is covered thoroughly, and where points of theory or application are not presented, the relevant references to the literature are given. Particularly welcome are the sections concerning the determination of the pore pressure parameters *A* and *B*, which form the basis of the concept of shear strength introduced by Skempton and Bishop in 1954. The book is well produced and contains many diagrams, detailed drawings and photographs of apparatus. Soil-mechanics engineers will welcome it as a work of reference, but its price will cause a student to debate the need for adding it to his own bookshelf.

THOMAS WHITAKER

Clinical Hæmatology in Medical Practice

By G. C. de Gruchy. Pp. xii+620. (Oxford: Blackwell Scientific Publications; Springfield, Ill.: Charles C. Thomas, 1958.) 50*s*. net.

IN the best organized institutions the physician and hæmatologist work in close collaboration. The hæmatologist must know enough about the clinical state of the patient to know which tests are appropriate, and the physician must know enough about hæmatology to be able to interpret the results. Dr. de Gruchy's book provides just this information. It gives an accurate balanced account of hæmatological disorders with enough clinical details to enlighten the hæmatologist and enough about the interpretation of technique for the physician. It would be very easy for such a book to become unwieldy, but Dr. de Gruchy has avoided this by the total omission of technical detail and the free use of tabulation. The presentation is somewhat dogmatic and it is this which makes the book so easy to read. But, of course, it is never possible to be dogmatic and agree with all workers on every subject. For example, it is probable that workers with experience in the surgical treatment of hæmophilic patients would not consider that a transfusion of 20 ml. of fresh plasma per kgm. body-weight would be likely to control bleeding. However, such details are really irrelevant; anyone wishing to undertake some very specialized treatment would naturally consult original papers on the subject and would not rely exclusively on a book, the main object of which is the general education of physicians and clinical pathologists.

R. BIGGS

Clinical Enzymology

Edited by Dr. Gustav J. Martin. Pp. vii+241. (London: J. and A. Churchill, Ltd., 1958.) 42*s*. net.

ALTHOUGH clinical enzymology is not a new sphere of activity in medical science it is a subject that has been greatly fostered by the purification and crystallization of enzymes during recent years. From this has come a realization that enzymes can be usefully administered parenterally in many instances. This book begins with a discussion of protein biology and the chemistry and biochemistry of enzymes which are of clinical value. The diagnostic use and the therapeutic action of enzymes are also considered and the book concludes with a discussion of future possibilities. The parenteral administration of trypsin in particular has been of value in the treatment of conditions involving intravascular clotting, in the treatment of infected wounds, and in a wide range of infections generally. On the whole, the anti-inflammatory action of the enzyme is the most striking. Other enzymes which have been used parenterally include streptokinase, deoxyribonuclease, hyaluronidase, and cholinesterase, but for the value of the use of most of these by parenteral administration only fragmentary evidence exists. It can be said without hesitation, however, that the medical use of parenteral enzymes is bound to grow and there is no doubt that clinical enzymology has come to stay.

F. G. YOUNG

Scientific and Learned Societies of Great Britain

A Handbook compiled from Official Sources. 59th edition. Pp. 215. (London: George Allen and Unwin, Ltd., 1958.) 35*s*. net.

THIS book, the third of its kind, derives from the "Yearbook of Scientific and Learned Societies", which ceased publication in 1939 after appearing almost continuously for more than fifty years. It is now edited by the British Council.

The greater part of the book consists of a list of nearly a thousand societies, ranging from the Royal Society down to the small local natural history societies, grouped under sixteen headings. Particulars of the objects, membership, meetings, publications, museum and library of each society are given. Some of the entries are of societies not strictly scientific, but inclusion is no doubt preferable to omission in compilations of this sort. The criterion is, in general, whether a society gives educational facilities to its members, or publishes original work.

There is also a list of the principal organizations conducting officially sponsored research, and a select bibliography on the organization of scientific research in Great Britain. In the former, universities, technical colleges and laboratories attached to commercial firms are, of course, not included; but neither are the industrial research organizations. These are officially sponsored since they receive Department of Scientific and Industrial Research grants, and they might usefully be brought into future editions.

BIOSYNTHESIS AND CONSTITUTION OF LIGNIN*

By Prof. KARL FREUDENBERG
University of Heidelberg

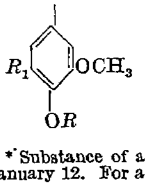
NEARLY forty years ago, by studying the kinetics of the degradation of cellulose, I obtained evidence that there exists a clear order in the large cellulose molecule, one glucose unit being bound to the next in the same way as in cellobiose[3]. This concept of a *uniform* chain, which was later adopted by H. Staudinger and W. N. Haworth, encouraged me to attack lignin, the other major wood constituent.

The problem was to decide whether lignin is a sort of molecular 'compost heap', or whether, like cellulose, it possesses an orderly structure. The second possibility was preferred as a working hypothesis.

However, lignin is a condensed system which cannot be hydrolysed, and the units from which it is built, though of similar types, are not identical. Analytical efforts to elucidate the lignin structure made but slow progress. It contains methoxyl[4], hydroxyl, and ether[5] groups, and can give 30 per cent of the theoretical yield of vanillin[6]. Formaldehyde[7] and *iso*-hemipinic acid (3-carboxy-4,5-dimethoxybenzoic acid)[8] are other products of degradation, and Hibbert[9] isolated a small amount of ketones by alcoholysis. In 1935, Holmberg[10] discovered that phenylcarbinol groups and their ethers are involved in the sulphite pulping process, and the Swedish school elucidated the specific nature of the phenylcarbinols responsible for this important reaction. Among these ethers are phenyl-coumarans, which had been proposed as constituents of lignin[11]. Despite these discoveries, it still remains impossible to construct a constitutional scheme for lignin from purely analytical information.

In 1875, Tiemann in Berlin cleared up the constitution of the glucoside coniferin (I) which is present in the cambium sap of conifers during the period of vegetation. In deciduous trees coniferin is found together with syringin. The present discussion is confined to coniferous wood.

Tiemann suggested that lignin and coniferin are related genetically[12], and this idea was used by Klason[13] throughout his work on lignin chemistry. H. Erdtman[14] showed that the product obtained many years ago by two French workers[15], who oxidized *iso*eugenol by means of mushroom oxidases, was in fact a phenylcoumaran similar in kind to that claimed to occur in lignin. This oxidation reaction provided a model for the formation of lignin, and in 1933 Erdtman[14] pointed out that lignin might be a dehydrogenation product of guaiacyl-propane derivatives with an oxidized side-chain.



(I) R and R_1 = H: coniferyl alcohol

(II) $R = C_6H_{11}O_5$; R_1 = H: coniferin

(III) R = H, $R_1 = OCH_3$: sinapinic alcohol

(IV) $R = C_6H_{11}O_5$; $R_1 = OCH_3$: syringin

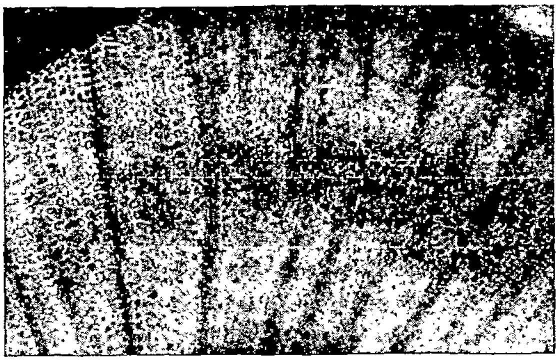


Fig. 1. Cross-section through a spruce sapling after administration of D-coniferin-β-^{14}CH

During the past eight years we have been studying the biosynthesis of lignin by the method of introducing various radioactive substances into spruce saplings. The needles of a small side twig are trimmed down, and the twig is allowed to suck up a solution containing the tracer[16]. It is found, when using radioactive D-coniferin, that the radioactivity is fixed within a few days in the region around the point of attachment of the branch, and radioactive lignin is obtained (Fig. 1). Afterwards, normal cells grow over the radioactive ones. Using L-coniferin, prepared from L-glucose and radioactive coniferyl alcohol, no radioactive lignin is obtained[16]. When radioactive phenylalanine is introduced, it is transformed into radioactive coniferin[17], which can be isolated from the plant after one or two days. After a further few days, we find once again that the radioactivity is fixed in that zone of cells which is in the process of lignification at the time of the experiment. It is astonishing how quickly the transformation of the phenylalanine into coniferyl alcohol, and the conversion of the latter to its glucoside, take place. Thus, coniferyl alcohol is derived from an acid of the C_6C_3 group, precursors of which are shikimic and prephenic acids.

We have, therefore, at our disposal ordinary natural lignin isolated from wood, lignin produced in the tree in the presence of radioactive coniferin, and lignin similarly formed in the presence of phenylalanine. Both coniferin and phenylalanine can be labelled at different carbon atoms.

But there is also a way of preparing lignin *in vitro*. If air is bubbled through a very dilute aqueous solution (less than 0·5 per cent) of coniferyl alcohol in the presence of mushroom laccase, at 20° C. and *p*H 5·5–6·5, a light grey-brown precipitate is formed. Depending on the enzyme concentration, the time required may be minutes or hours. The precipitate accounts for 80–90 per cent of the coniferyl alcohol used. From it some substances of low molecular weight can be extracted by butanol at ordinary temperatures, and the residue is biosynthetic lignin produced by enzymatic dehydrogenation of coniferyl alcohol. Cambium laccase can be used instead of mushroom laccase[19], and the biosynthesis can also be effected by means of horse-radish peroxidase and very dilute hydrogen peroxide solution[19]. Radioactive coniferyl alcohol labelled at different carbon atoms can also be used for these *in vitro* experiments.

---

* Substance of a lecture given in the University of Cambridge on January 12. For a recent survey of work on lignin, see refs. 1 and 2.

Our array of lignin preparations suitable for examination is therefore increased by these biosynthetic products. Extensive comparison, both physical and chemical, of the best biosynthetic and natural lignin preparations leads to the conclusion that they are identical in their properties[2,17,20,21]. Analogous degradation products from both were either radioactive or not, depending on the site of the labelled atoms in the monomeric tracer. The molecular weight in both cases was of the order of 10,000. Details may be seen in publications of the Heidelberg school.

The middle part of Fig. 2 represents a cross-section through the cambium of spruce wood; the cambium cells can be recognized by the nuclei which have been included. On the inner side of the cambium on the right, the delicate, newly formed cells are converted gradually into mature wood, while on the left they form bark. When the cell walls have become quite thick, wood formation is ended. The lower part of Fig. 2 shows a section which has been stained with phloroglucinol and hydrochloric acid. The lignin is [redacted] deep red, and is indicated by dark portions on the drawing. During the vegetative period the tissues of the cambium and adjacent cells contain large amounts of the glucoside coniferin. Laccase and, to a smaller extent, peroxidase, are also present in the cell sap[19]. But these enzymes cannot attack coniferin; they can only build up lignin from coniferyl alcohol. This led to the conclusion that a β-glucosidase must also be present in the tissue, but we were unable to extract it. We therefore used a dilute solution of the synthetic glucoside, indican, which can be split by glucosidase into glucose and indoxyl. Indoxyl on exposure to the air is oxidized to indigo. (M. W. Beijerinck[23] used a somewhat similar method with the sap of *Isatis tinctoria* to indicate the location of emulsin in almond sections.) In our case the blue colour of indigo develops rapidly between the fresh cells and the mature wood (upper part of Fig. 2)[22]. Here are the very cells in which lignification is taking place. The prediction of the presence of a β-glucosidase and its direct observation are a strong argument in favour of our theory of the biogenetic pathway of formation of wood. Coniferin is produced from C_6C_3 acids *en route* from the point of introduction to that of lignification. It diffuses into the newly formed cells, where it is hydrolysed to glucose and coniferyl alcohol, and the latter, coming into contact with laccase and peroxidase, is transformed into lignin. The cell dies as soon as the hollow spaces of the cell wall are filled up with lignin.

To recapitulate: coniferin, which originates from a C_6C_3 acid, is an intermediary substance which is converted by the action of a β-glucosidase into coniferyl alcohol, and this hydroxy-cinnamic alcohol is then transformed by laccase and peroxidase into lignin. Natural lignin and lignin formed *in vitro* are identical. It is thus proved conclusively that spruce lignin is a C_6C_3 substance of the guaiacyl type, but the details of its constitution remain just as obscure as ever.

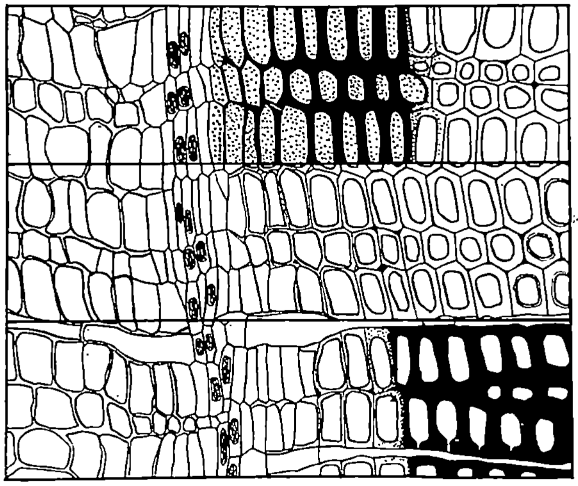

Fig. 2. Cross-section (schematic) through spruce cambium. Middle part unaltered, bottom part treated with phloroglucinol hydrochloride, top part treated with indican

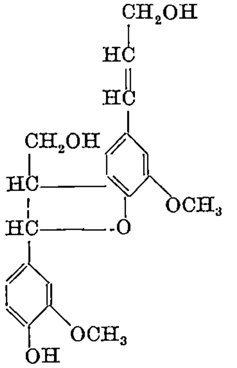
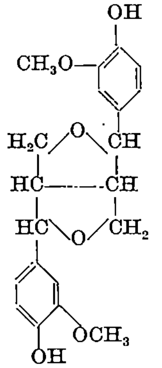
However, there is one more way of approaching this question. As is mentioned above, the crude biosynthetic lignin contains substances of relatively low molecular weight. If lignin formation is interrupted at a certain stage, namely, when all the coniferyl alcohol has been used up and only very little lignin has been formed, a large amount of these intermediates of low molecular weight is obtained. The intermediates of the *in vitro* preparation form the vital key to the *in vivo* processes of lignin synthesis. So far, the following intermediates have been isolated[24–27]:

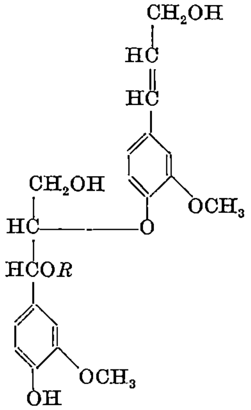
(*A*) dehydro-diconiferyl alcohol (V); approximate amount 20 per cent of the original amount of coniferyl alcohol; (*B*) DL-pinoresinol (VI); about 20 per cent; (*C*) guaiacylglycerol-β-coniferyl ether (VII); about



(V) Dehydro-diconiferyl alcohol (substance *A*)

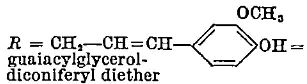


(VI) Pinoresinol (substance *B*)



(VII) *R* = H : guaiacylglycerol-β-coniferyl ether (substance *C*)

(VIII)



$R = CH_2—CH=CH—$ OH =
guaiacylglycerol-diconiferyl diether (substance *H*)
(XIII) $R = CH_3$
(XIV) $R = C_{12}H_{21}O_{10}$

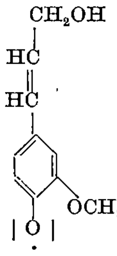
30 per cent or more ; (*D*) coniferyl aldehyde (1 per cent) ; (*E*) the aldehyde of V (4 per cent) ; (*F*) the aldehyde of VII (3 per cent) ; (*G*) dehydro-dipinoresinol (4 per cent) ; (*H*) guaiacylglycerol-diconiferyl diether (VIII) ; 15 per cent. A further product (*J*) is guaiacyl-glycerol-β-coniferyl-γ-dehydro-diconiferyl-diether, corresponding to (VIII). The yield of each substance has its individual maximum at a different stage of formation of lignin. Addition of the percentages quoted above would be misleading.

Other intermediates are still under investigation. The substances *A*, *B* and *C* are the major constituents of the mixture ; *E*, *F*, *G* and other products are derived from these three ; *G* is a diphenyl derivative, built up of two molecules of (VI), minus two hydrogen atoms. In addition to these substances, the presence of many others, the total quantity of which is small, can be demonstrated by paper chromatography. By the continued action of the enzymes, these substances are dehydrogenated further and condense with each other or with coniferyl alcohol to form the lignin polymolecule[30]. A subsidiary amount of linking may be caused by a simple addition without loss of hydrogen. This is the case with substances *H*, formula (VIII), and *J*. There is evidence that such a condensation occurs through the addition of the primary carbinol group of coniferyl alcohol to a quinone methide group (formula XII, see below).

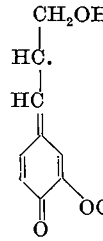
The above formulæ contain all the elements of structure which are necessary to explain the chemical behaviour of lignin : (VII) contains a phenyl carbinol group, (VI) and (VIII) contain aliphatic benzyl alkyl ethers, and (V) is a benzyl aryl ether. These groups are involved in the sulphite and sulphate pulping processes. Cinnamic aldehyde groups, which are responsible for the colour reactions of lignin, are also present. *Iso*hemipinic acid is obtained from (V) and is radioactive when the β-carbon atom of the coniferyl alcohol side-chain is labelled with carbon-14[17]. It is noteworthy that all these intermediates as well as lignin itself are optically inactive.

It is not difficult to explain the origin of all of these substances. Enzymatic attack on coniferyl alcohol causes the removal of a phenolic hydrogen atom, leaving a radical which can be written in various mesomeric forms, including (IX), (X) and (XI). Structures (X) and (XI) can combine to form a quinone methide which, by rearrangement, yields (V), while two units of the limiting structure (X) can combine and become rearranged to pinoresinol (VI). Similarly, (VII) could arise from the combination of (X) and (IX), followed by the addition of water to the resulting quinone methide (XII). With coniferyl alcohol, (XII) forms the labile substance (VIII)[27], and similarly with methanol or cane sugar, (XIII) and (XIV) result ; these have been isolated.

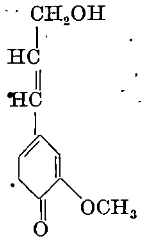
So far, it has not been possible to furnish direct evidence for the formation of the radicals ; their dilution is too great and life-time probably much too short. The quinone methides have been observed recently by direct ultra-violet measurements[28], and their half-life is estimated at about 60 min. under the conditions of measurement. Well-founded chemical evidence for the intermediate formation of (XII) has also been obtained. If the enzymatic dehydrogenation of coniferyl alcohol is carried out in water containing 30 per cent methanol, a new substance appears among the regular ones[28]. It is the γ-methyl ether (XIII) of (VII), and is formed by addition of methanol to the quinone methide (XII), thus providing direct proof of the transitory existence of (XII). *J* is an addition product of (XII) and *A*. Even cane sugar can be added to (XII) in the same way, the product being (XIV)[28]. This demonstrates the manner in which lignin is combined with the carbohydrates of the cell wall.



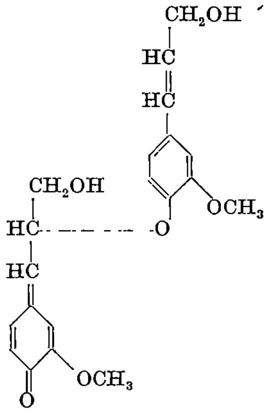
(IX)



(X)



(XI)



(XII)

The theory of lignin constitution developed above explains why the C_6C_3 units in conifer lignin, although originating from a single substance, namely, coniferyl alcohol, occur in such a vast number of different forms. Another remarkable fact is that lignin and also the intermediates, despite their many asymmetrical atoms, are all optically inactive. This is also explained by the intermediate formation and mesomerism of the radicals, which are optically inactive. The action of the enzymes is restricted to dehydrogenation of phenolic groups. All subsequent reactions, such as the formation of quinone methides by the interaction of the radicals, the addition reactions of the quinone methides and possibly polymerization reactions, proceed automatically without further regulation by enzymes. Even a solution of copper sulphate in water transforms—albeit slowly—coniferyl alcohol in the presence of oxygen into the same intermediates, and finally into lignin.

It has been mentioned above that the enzymatic dehydrogenation of coniferyl alcohol does not yield biosynthetic lignin quantitatively. The reason is that, even during the course of its formation *in vitro*, the lignin is partially degraded by further dehydrogenation. When a fine suspension of either natural or artificial lignin in water is subjected to the dehydrogenating activity of the enzymes[19] laccase or peroxidase, it undergoes the same degradation. This process is closely related to humification and destruction of phenols in the soil. Lignin can therefore be built up and degraded by the same enzymes. In the organized system in the plant, only formation occurs, because the action of the enzymes ceases when the tissue has been filled up with lignin. But when the dehydrogenases approach from external sources, as in the case of attack by wood-rotting fungi, the degradation process sets in. Hence it is understandable why mushrooms and wood-rotting fungi contain laccase and peroxidase — preferentially in the mycelium and stipe—although they do not produce lignin. They require the laccase for the degradation of lignin or other phenolic substrates of the soil or wood.

Lignin of deciduous wood is built up of a dehydrogenated mixture of coniferyl and sinapinic alcohols (I and III). Sinapinic alcohol, which occurs in trees as its glucoside syringin (IV), has never been found as the exclusive building unit for a natural lignin. The explanation is given by the following experiment. When laccase or peroxidase acts on sinapinic alcohol, 80–90 per cent syringa-resinol (5 : 5′-dimethoxy derivative of pinoresinol, VI) is formed[19,29]. The residual 10–20 per cent consists of the same degradation products as are obtained when pure syringa-resinol is exposed to dehydrogenase[19]. Obviously the intermediates containing phenyl ether bonds corresponding to (V) and (VI) cannot be formed owing to steric hindrance. Following enzymatic degradation of syringa-resinol, 3 : 5-dimethoxy-*p*-quinone has been [redacted][19].

The question is therefore answered as to whether lignin has an intelligible structural principle, and it is also explained why its architecture is more intricate than that of any other polymolecule[30]. So far, the principles involved in the formation of lignin have not been applied to the technical synthesis of other materials.

INFLUENCE OF THE ANTERIOR PITUITARY ON THE AGEING PROCESS IN THE OVARY

By DR. E. C. JONES and PROF. P. L. KROHN*

Department of Anatomy, University of Birmingham

TWO alternative ways of defining and measuring the rate of ageing are open to us. The first is an actuarial analysis of the increasing vulnerability of an ageing population. The second is based on the individual, and attempts a causal analysis of the ageing process at a chosen level of biological organization. For this purpose a particularly suitable method is to form heterochronic chimeras, in which tissues of one age are transplanted into the environment of another age. It is obviously desirable to choose a system for study which shows clear-cut signs of deterioration with age, but the visible changes that can be expressed quantitatively vary widely from one system to another. The central nervous system is one which could possibly be studied, and Burns[1], making use of Brody's[2] figures, has calculated that 100,000 neurones are irretrievably lost from the human cerebral cortex every day. The glomeruli in the kidney probably constitute another field of study. But neither appears to provide as advantageous a situation as does the female reproductive system, where the changes in overall reproductive capacity are very easily measured and can be correlated with a gradual loss of oocytes from the ovaries.

It has been universally accepted that the ovaries finally lose all the oocytes which they once contained. But since the middle of the nineteenth century there has been vigorous controversy about whether neo-formation during adult life can add to the original complement or whether the female has to make the best she can of a limited number of oocytes with which she is endowed in early life. The problem has been exhaustively reviewed from time to time as opinion has oscillated in favour of one theory or the other. The most notable recent reviews[3,4] have been based on a series of quantitative observations and planned experiments which decisively tip the balance in favour of the endowment theory. These data clearly show that the decline in the total number of oocytes begins early in life and continues regularly with increasing age. They also show that no experimental situation has been contrived in which any part of the ovary can be convincingly demonstrated to give rise to fresh oocytes.

---

* Nuffield Senior Gerontological Research Fellow.

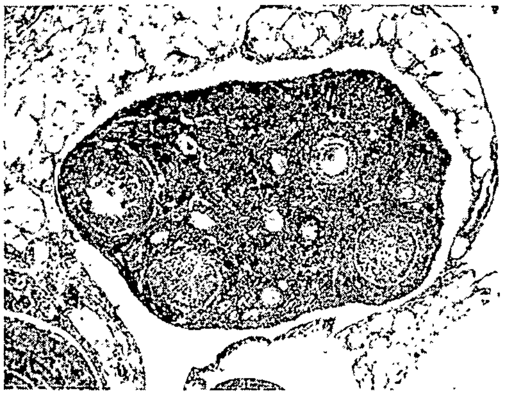

Fig. 1. Ovary from 346-day-old *CBA* strain mouse hypophysectomized 264 days earlier. (× 60)

Like the neurones, therefore, the female germ cells appear to be unable to reproduce themselves by mitotic division and are irreplaceable. It is because an understanding of this limiting factor would have such relevance to the study of the pattern of fertility that an analysis of the processes underlying the disappearance of oocytes has been undertaken.

Removal of oocytes at ovulation, and the atresia of other Graafian follicles which, for reasons that are not yet clear, fail to ovulate, can readily account for some of the loss. The decline in numbers, however, is too great and begins too early in life (immediately after birth in mice and rats), when there are no large follicles, for this factor to do more than provide a partial explanation. It has long been apparent that the major part of the loss must be due to some different process that affects the small follicles.

In addition to controlling the loss of oocytes at ovulation, it is possible that the pituitary may have a further influence on the ageing process in the ovary. The limited purpose of the present experiments was, therefore, first—to compare the rates of loss of oocytes in normal and hypophysectomized mice ; and second—having established that hypophysectomized animals lose their oocytes more slowly, to show by transplantation methods that the oocytes in ovaries, whose rate of ageing has been retarded by hypophysectomy, remain fully viable, even when their chronological age is greater than the age at which reproduction has ordinarily ceased. The labour involved in counting, and the limitations imposed by immunological considerations virtually restrict one's choice of animal in experiments of this kind to the mouse. All the experiments reported here have been carried out on mice of the *CBA* strain, whose exceptionally rapid normal loss of oocytes makes them particularly convenient to use. Further studies (to be reported elsewhere) have shown that the influence of hypophysectomy on the numbers of oocytes also extends to other strains (*A* and *R*III and hybrid crosses) in which we have not yet, however, carried out transplantation experiments.

Methods and Results

The mice were hypophysectomized at an average age of 39 days by Thomas's[5] method. Only those the sellæ turcicæ of which were shown by serial sections at the end of the experiment to be free of pituitary remnants have been included in the results. The technique adopted for counting the oocytes was the same as that used by Mandl and Zuckerman[6] in rats.

The results of the counts in 52 normal *CBA* mice, ranging in age from 1 to 437 days, can be expressed by the equation :

$$\log y \text{ (total number of oocytes)} = 4\cdot049 - 0\cdot00711\, x \text{ (days)}$$

and for 16 hypophysectomized *CBA* mice aged from 44 to 346 days at autopsy :

$$\log y = 3\cdot735 - 0\cdot00247\, x$$

The two regression coefficients are significantly different from each other ($P < 0\cdot001$). They imply that normal *CBA* ovaries lose about 30 per cent of their population of oocytes every 20 days and hypophysectomized animals only about 10 per cent. For example, the ovaries of a 320-day old normal *CBA* mouse would be expected to contain about 70 oocytes whereas the ovaries of a hypophysectomiz[redacted] of the same age would contain about 880 oocytes—more than 12 times as many. The histological differences between the two types of ovary are exemplified in Figs. 1 and 2. The ovary of the hypophysectomized mouse (Fig. 1) is much smaller and contains neither large follicles nor corpora lutea. But there are far more small oocytes in it, and the usual signs associated with ageing in the ovary (for example, ceroid, pigment and anovular follicles) are much reduced.

There are no precise histological criteria which permit one to distinguish categorically between normal and atretic small follicles. Nevertheless, an attempt was made to separate the two categories when the original counts were being made. The ratio of normal to atretic small follicles was found to be 74 : 26 in hypophysectomized *CBA* mice and 49 : 51

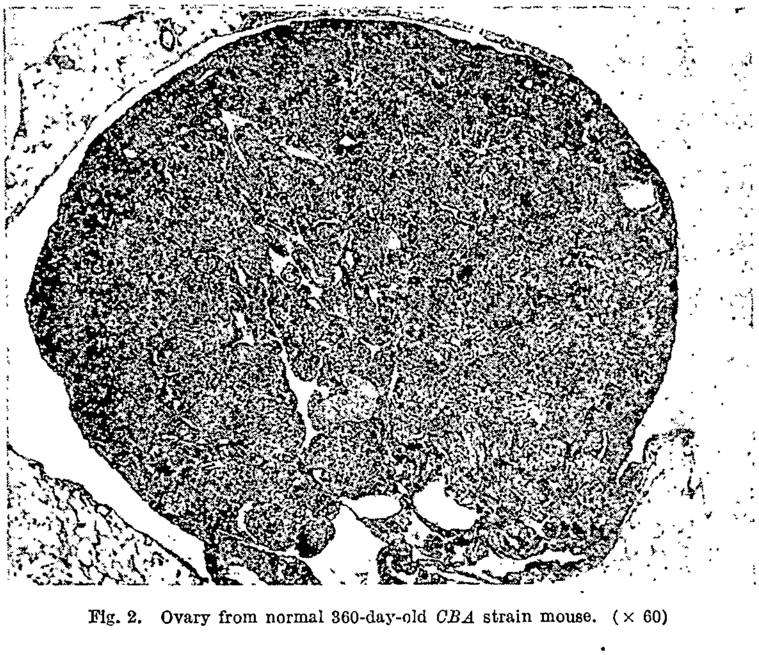

Fig. 2. Ovary from normal 360-day-old *CBA* strain mouse. (× 60)

in normal mice. Afterwards, five observers who were not told that the sample contained ovaries from hypophysectomized animals were asked to estimate the ratio of normal to atretic follicles in a smaller sample. They evidently varied in the subjective criteria which were used to assess the normality of an oocyte, since the proportion thought to be normal differed, but all agreed that the proportion was greater in those ovaries which had come from hypophysectomized animals.

The reproductive capacity of the ovaries of the hypophysectomized mice was tested by transplanting them orthotopically into young and old mice of the same strain, using a surgical technique which will be described elsewhere.

The first host mouse was a 456-day old *CBA* female which had given birth to 8 litters, the last 2 months earlier. Her ovaries, which were removed immediately before the unilateral orthotopic transplantation, contained only anovular follicles and remnants of corpora lutea. The hypophysectomized donor of the transplanted ovary was 311 days old and had been hypophysectomized for 273 days. The number of oocytes in the transplanted ovary was estimated from the regression equation at 460.

The host had previously shown irregular periods [redacted] cornification ; her cycles remained infrequent and irregular after the grafting operation. She was paired with a male of proved fertility but never showed any signs of having mated.

The ovarian pad of fat, containing the graft and Fallopian tube, was removed 72 days later for histological examination. Serial sections showed that the operation had been technically successful, in that there were no obvious barriers to the free passage of ova from the graft to the Fallopian tube and uterus. The graft had enlarged and, among the total of 270 follicles which remained, contained 7 follicles with antra. There were, however, no corpora lutea nor signs of luteinization and the nuclei of stromal cells retained the cartwheel appearance, typical of a deficiency of luteinizing hormone, which is found with increasing frequency as animals get older[7].

Three young spayed virgin *CBA* females were given single orthotopic ovarian transplants. The first was 62 days old and received the second ovary from the hypophysectomized mouse which had provided the graft for the old mouse referred to above. Evidence that the graft was producing œstrogen soon appeared, the vaginal smear being fully cornified within a week. An interval of pseudo-pregnancy followed mating, and was succeeded by a pregnancy which resulted in the birth of three normal young. A second litter of two died, but a third litter of six was entirely healthy. The grafted ovary was 437 days old when the third litter was born, an age which is well past the average (352 days) at which reproduction ordinarily ceases in the *CBA* strain of mice.

The other two young females (92 days old) received single transplants (estimated to contain 290 oocytes each) from a 392-day old mouse hypophysectomized 354 days earlier. Vaginal cornification returned 4 and 5 days after the operation. One mouse has given birth to two litters, each containing two young, the second litter being born when the grafted ovary was 498 days old. The other mouse has mated repeatedly and has shown a succession of pseudo-pregnancies without becoming pregnant. It is assumed that adhesions have developed between the surface of the graft and the ovarian capsule which prevent the eggs from reaching the tube. This unfortunate complication of the operation is fairly common.

Discussion

The results show that after hypophysectomy oocytes are lost much more slowly from the ovary and that the proportion of small follicles showing the histological signs of atresia decreases. The ageing process, as it affects the ovary of the mouse, is therefore retarded when the pituitary is removed.

Earlier studies of the effect of hypophysectomy on the number of oocytes in the ovary purported to show that the number actually increased after hypophysectomy in rats[8,9]. The experiments were not, however, intended to show any relationship between pituitary secretions and the destruction of oocytes by atresia, but to prove that the pituitary ordinarily prevents the ovary from engaging in the neoformation of oocytes at the rate it would choose if freed from restraint. However, Ingram's[10] much more satisfactorily controlled experiments failed to confirm the observations on which this conclusion was based. Instead they clearly demonstrated that the number never exceeded the normal pre-operative control figures, and indeed, continued to decline after hypophysectomy. Although Ingram's hypophysectomized rats did lose their oocytes more slowly than the normal animals, he was unable to show that the difference between the two regression coefficients relating age and numbers of oocytes was statistically significant.

Our results can best be explained by assuming that hypophysectomy removes an unidentified atresia-promoting factor in addition to stopping the loss from ovulation. An alternative but more cumbersome explanation would be that some extra-pituitary factor is no longer able to act, the pituitary hormones normally playing the sort of permissive part which is sometimes attributed to adrenal cortical hormones in other endocrinological situations. It seems unlikely that the factor is any one of the gonadotrophins since the rapid loss of small follicles by atresia in the normal animal precedes any evidence that gonadotrophins are being released by the pituitary. It is tempting to choose somatotrophin from among the recognized hormones of the anterior pituitary, on the basis of its known influence on cellular growth and differentiation. At present there is, however, no experimental justification for such a choice.

But the population of oocytes does not remain intact even after the removal of the atresia-promoting factor by hypophysectomy. On the contrary, the negative slope of the regression line differs significantly from zero, and oocytes continue to be lost, even if more slowly than normal. It must therefore be assumed that yet another unknown process, which is independent of the pituitary, promotes the loss of oocytes. Ageing of the ovary, as measured by the overall loss of oocytes, therefore depends on the combined effects of at least three separate factors—one concerned with the maturation of follicles for ovulation, a second unidentified pituitary principle and a more general influence whose effect persists in the absence of the pituitary. As mentioned earlier, the cell populations of several of the other organs in the body are subjected to a process of attrition with the passage of time. Analysis revealed that this process, as it affects the ovary, has a complex structure, but no one knows how far the behaviour of the ovary is unique, or how far it represents a pattern which also applies to these other organs. Only further experiments can decide whether, for example, the decline with age in the number of cortical neurones is retarded by hypophysectomy and whether some loss of cells persists even in the absence of the pituitary.

The transplantation experiments reveal, in addition, that the oocytes and follicles which remain after long-term hypophysectomy are entirely viable and do not necessarily deteriorate simply with the passage of time. They respond normally to the appropriate gonadotrophic stimuli; the follicles ovulate and if the ova are fertilized they are capable of developing into normal young. Equally, the corpora lutea which develop from old granulosa cells are able to maintain a normal pregnancy.

The behaviour of grafts of ovaries from a hypophysectomized mouse depended entirely on the nature of the environment in which they were placed. In an old host the ovary failed to do more than show that its small follicles could grow to Graafian size, whereas complete reproductive capacity was demonstrated in the young host. These observations reinforce earlier suggestions that, although the pituitary continues to produce gonadotrophins, it no longer does so in the proportions which are necessary for reproduction. In particular, it suggests the possibility that the production or the release of ovulating and luteinizing hormones is impaired.

OBITUARIES

Mr. Frank Twyman, F.R.S.

The scientific world is the poorer for the passing of Mr. Frank Twyman on March 6. He was born in Canterbury in 1876, and attended Simon Langton's School in that city. He went to the Finsbury Technical College and later as Siemens Scholar to the Central Technical College, London. He then obtained a post as cable tester in the Fowler Wiring Cables Co., but he found the work irksome, especially night shifts, and went to Otto Hilger, as he characteristically put it, to "have a rest". (Later he described the work as "a most complicated way of earning a living".) Otto Hilger had succeeded his brother Adam in charge of the firm of Adam Hilger; he died in 1902 and the management passed to Twyman, although only twenty-six years old at the time. Two years later the firm was incorporated with Twyman as managing director, a post which he held until 1946. In 1948 the firm amalgamated with E. R. Watts and Son, and he served as a director until 1952, after which he became technical adviser.

Twyman was a man of tireless energy; until 1910 he designed all the new instruments completely, making all detailed drawings and testing and adjusting the instruments himself. He made many innovations in the production and testing of high-quality components, and was always vigilant in seeking new methods. He believed in sharing his knowledge with others, and for this reason published his book, "Prism and Lens Making". His developments in interferometers for testing optics alone would entitle him to a high place in innovation in industry. Twyman had a deep knowledge of glass-making and an original outlook which benefited makers of high-quality optical glass. He helped to start the Optical Materials Committee, which was of great value during the First World War.

Twyman's outstanding achievement was in the field of spectrochemical analysis. Although the possibility of the use of spectroscopy for chemical analysis, particularly of metals, had been known since the middle of the past century, it had not found favour. He became convinced of its importance, and in 1904 produced the constant-deviation spectrometer with the wave-lengths of the lines displayed on a helical drum. This was a success, bu[redacted]h analysts. The range was restricted to the visible region, whereas the lines of most interest for metal analysis lie in the ultra-violet. Therefore, he designed the fixed medium quartz spectrograph, which shows a wide range of wave-lengths on a photographic plate, and also a large quartz spectrograph of greater dispersion. These appeared in 1910, but with one exception (the American Brass Co.) he failed to persuade analysts of their usefulness, although ready sales were made for academic purposes. Two events broke the deadlock: the American Brass Co. published the results of nine years successful routine-control of brass production, and two firms, one in Germany and one in the United States, made equivalent instruments and inspired the publication of investigations made by means of them.

He was also busy with work in other regions of the spectrum. He made vacuum ultra-violet spectrographs, the first going to Bohr's laboratory in Copenhagen. Against the advice of Paschen, who affirmed that the infra-red region would never be of industrial interest, he made an infra-red instrument, the first of several. X-ray spectrometers were made for Laby and others, and instruments for the investigation of crystal structures by X-rays.

Twyman was elected a Fellow of the Royal Society in 1924. The John Price Weatherill Medal of the Franklin Institute of Washington was presented to him in 1927, the Duddell Medal of the Physical Society in 1927 and the Gold Medal of the Society of Applied Spectroscopists of the U.S.A. in 1956.

He was interested in general matters also, bringing an original mind to bear upon economics and education. He published a small book entitled "Some New Proposals for the Amelioration of the Balance of Payments Position", and another called "Apprenticeship for a Skilled Trade". He was interested in music, gardening, literature and the theatre, and had a wide knowledge of old music-hall songs. For many years his lunch consisted of a glass of milk, which he drank to the accompaniment of his violin—he used to explain that he was "trying to become a third-class amateur". Those who worked with him knew that his apparent ingenuousness hid a clear appraisal of the situation; when a junior brought him a problem, he would say, "and what do *you* recommend?" It is no wonder that he was much loved and respected by his staff. A. C. MENZIES

Prof. Thomas Thomson

WITH the recent death of Prof. T. Thomson we saw the passing of a person who, with singular devotion, had spent his whole life in the service of one educational institution.

When Thomson, a Londoner, entered the University College of North Wales, Bangor, in the first decade of this century, he was somewhat older than the average run of students at the time, and after reading for honours in chemistry, and taking a first, he continued to read forestry under Prof. Fraser Story, then head of that Department.

During the First World War, Story was called to London, and Thomson worked in Wales on problems of woodland felling and timber supplies. This gave him an admirable introduction to the Welsh countryside and to the mind of the countryman, a most valuable asset early in a professional career.

In 1919, the Forestry Commission was set up. Story stayed on in London as its education officer and Thomson returned to Bangor to take charge of the Forestry Department, first as an independent lecturer and latterly, before his retirement, eleven years or so ago, as professor. This was a period of expansion and adaptation in the subject, to meet the new and expanding economy of the new State forest policy in Britain, together with the continuance of training of forest officers for work in the Dominions and overseas.

It was also the period of transfer of activities from the Old Buildings in the Penrhyn Arms Hotel to the Memorial Buildings in Deiniol Road in the mid-twenties. It also witnessed the ever-expanding provision of field courses of training, extramural to the Department at Bangor. Before the War there had been established at Penisa'r Glyn near Chirk in the Ceiriog Valley, Denbighshire, an experimental forestry unit, in the layout of which Thomson was the prime mover. Now, after the War, there followed comprehensive and extensive practical forestry courses in the field in the French State forests, with their long established and tested traditions. This was eventually extended to embrace collateral courses in the newer State forests of Britain, as these developed and matured.

As an academic discipline the subject suffered severely at this time from the serious lack of authoritative standard text-books in English. This Prof. Thomson set himself to remedy, and in due course appeared his English translation of the classic text of "The Foundations of Silviculture" from the German of Busgen and Munch. This was followed by Thomson's own "Outline of Forestry", less ambitious in scope, but withal a very worthy students' manual.

During the Second World War, and the second severe onset on the native timber resources of Britain in one short generation, Thomson gave admirable service, outside his Department, in operating the State scheme of grants for new planting and replanting of timber trees. His thorough and extensive knowledge of conditions in the field in Wales, based on his initial experience during the First World War and extended since, and his natural endowments in the field of human relationship made him a first-rate agent in working this policy—indeed a very successful ambassador among estate and woodland owners.

He had retired from the chair before the Department made its second move to the present site at the corner of Deiniol Road and Glanrafon Hill, but it gladdened his heart to see, so firmly established and so full of promise to the future, a pulsating and virile school that he had done so much to bring into being and to support in its infancy.

Prof. Thomson served his College well in the field of internal administration—a field of service he rather delighted in—as curator of the College grounds, in Board of Faculty, in Senate and as Dean. He was never forward in the rough and tumble of argument and advocacy in the early stages of discussion of any issue, but invariably he came in towards the end with words of wisdom and sagacity. He was a very sound dialectician, a loyal colleague and a sturdy pillar of the Old Students' Association of the College.

Prof. Thomson was twice married, first to Miss Gwen Phillips, eldest daughter of the late Reginald W. Phillips, first professor of botany in the College, and secondly to Miss Connie Izard, a member of the College Music Trio, who survives him.

R. ALUN ROBERTS

Mr. Cyril Barnard

MR. CYRIL CUTHBERT BARNARD, librarian of the London School of Hygiene and Tropical Medicine, and author of the Barnard system of classification for medical libraries, was killed in a road accident on March 6. Son of Harry Barnard, an artist specializing in the design of Wedgwood ware, he was born at St. Margaret's, Middlesex, on July 23, 1894, and was educated at the Stationers' Company School and at the London School of Economics. In 1914, he became a library assistant at the Royal Society of Medicine and in 1918 assistant librarian at the Wellcome Historical Medical Library. During 1921–28 he served as librarian of the Tropical Diseases Library, and in 1929 took charge of the library of the London School of Hygiene and Tropical Medicine in its new building in Keppel Street.

Mr. Barnard graduated B.A. (London) with honours in 1922, and two years later obtained the diploma of the School of Librarianship. In 1931, he was awarded the honours diploma of the Library Association for a thesis entitled "A Classification for Medical Libraries", which was published in 1936. A second enlarged edition, "A Classification for Medical and Veterinary Libraries", came out in 1955. Mr. Barnard was elected a Fellow of the Library Association in 1925, served on the Council of the Association and as secretary of its University and Research Section, and in 1947 became chairman of the newly created Medical Section. In 1953, he was joint honorary secretary of the First International Congress on Medical Librarianship held in London. In 1952, he was invited by the World Health Organization to reclassify its library at Geneva according to his system. At his own library, which his expert knowledge and his devotion made one of the finest of its kind in the world, he introduced special courses of instruction in the use of the library for students.

A member of the Society of Friends, linguist, historian, and a friendly, cheerful, approachable, and quietly firm personality, Mr. Barnard will be greatly missed in medical library circles. W. R. BETT

NEWS and VIEWS

Anti-Locust Research Centre:

Dr. B. P. Uvarov, C.M.G., F.R.S.

Dr. Boris Petrovitch Uvarov, who recently retired from the directorship of the Anti-Locust Research Centre, London, was born in Uralsk in 1888. At the end of the First World War he was a lecturer in zoology and entomology at the Georgian State University, Tiflis. He had already had a distinguished career in Russian entomology following his graduation at the University of St. Petersburg. It was while working as director of the Stavropol Bureau of Entomology on the control of locusts in 1912 that he recognized the conspecificity of two 'species' of locusts as the solitary and swarming phases of *Locusta migratoria*, a discovery which was to revolutionize work in this field.

Uvarov was also keenly interested in Acridid taxonomy, so that he was able to accept the invitation extended to him in 1920 by Dr. G. A. K. Marshall, director of the Imperial Bureau of Entomology, to work in London. As assistant entomologist and later as senior entomologist he worked at that Institute on the identification of Orthoptera and Hemiptera at the British Museum (Natural History). During this time he published numerous important papers on the taxonomy and biogeography of the Acrididae which brought him much acclaim and he rapidly became the world authority on this family. But Uvarov was more than a taxonomist, and such works as "Locusts and Grasshoppers" (1928), "Insect Nutrition and Metabolism" (1928) and "Insects and Climate" (1931) placed him in the forefront of entomological workers.

Meanwhile, the control of locusts was becoming more and more important and he began to devote most of his time to studying this problem. Towards the end of the Second World War the danger of famine in the Middle East and in East Africa became acute, owing to the desperate shortage of shipping. When, therefore, the Colonial Office set up the Anti-Locust Research Centre in 1945, Uvarov was appointed director. Under his inspired leadership and as a result of very hard work involving extensive travel, the Centre grew from strength to strength and is now generally recognized as the most important institute of its kind in the world. Its great reputation and international influence may safely be attributed to Dr. B. P. Uvarov. He was appointed C.M.G. in 1943, became a Fellow of the Royal Society in 1950 and is now president of the Royal Entomological Society, London. He holds various foreign decorations, including the Chevalier, Légion d'Honneur and Commandeur de l'Ordre Royal de Lion of Belgium.

Dr. T. H. C. Taylor

T. H. C. Taylor, who has been appointed to succeed Dr. Uvarov as director of the Anti-Locust Research Centre, graduated at Reading University College. In 1925 he went out to Fiji as government entomologist to assist Dr. J. D. Tothill in his investigation of the problem of the coconut moth (*Levuana iridescens*), which had been causing extensive damage to the coconut plantations. He travelled widely in Melanesia and Indonesia in search of parasites, and as a result of this work the moth was brought completely under control. The results were published by Tothill, Taylor and Paine in 1930 in a massive report on this classic example of successful biological control. In 1935 he was transferred to Uganda, where he specialized on cotton pests. In 1944 he joined the staff of the Commonwealth Institute of Entomology, becoming assistant director in succession to Dr. W. J. Hall, who had been promoted to director. In 1953 Dr. Taylor joined the Anti-Locust Research Centre as deputy director. Since then he has made many tours of inspection of locust stations in Arabia and Africa.

National Agricultural Advisory Service

Sir Robert Rae, director of the National Agricultural Advisory Service, who is to retire on July 31, was formerly professor of agriculture in the University of Reading (see *Nature*, 153, 400; 1944). In 1944 he was appointed British agricultural attaché in Washington and agricultural adviser to the U[redacted]dom High Commissioner in Ottawa. In 1945 he became provincial advisory officer in the National Agricultural Advisory Service, and was promoted to under-secretary in 1947. He was appointed director of the National Agricultural Advisory Service in 1948.

Sir Robert Rae is to be succeeded as director by Mr. J. A. McMillan, at present senior education and advisory officer. After being wounded in the First World War, Mr. McMillan graduated at the University of Edinburgh in 1919. He afterwards became lecturer in agriculture in the University of Leeds, and agricultural organizer to the Lincoln (Lindsey) and Cambridgeshire County Councils. He was seconded during the Second World War to the Cambridgeshire War Agricultural Executive Committee. On appointment to the National Agricultural Advisory Service in 1946 he became provincial director, Eastern Province. He was promoted to senior education and advisory officer in 1948.

Mr. W. E. Jones, at present director of the National Agricultural Advisory Service in Wales, who will succeed Mr. McMillan, graduated with honours in agriculture at the University College of Wales, Aberystwyth. In 1946 he was appointed to the National Agricultural Advisory Service as a grassland husbandry advisory officer, and in 1950 became county advisory officer. He was appointed deputy director for Wales in 1954, and in 1957 he became director of the Service in Wales.

Mr. H. E. Evans, at present deputy director of National Agricultural Advisory Service in Wales, who is to succeed Mr. Jones, graduated with honours in agriculture at the University College of North Wales in 1934. He then spent six years with the Agricultural Economics Department at Aberystwyth. He was associated with the War Agricultural Executive Committees in England from 1940 until he joined the National Agricultural Advisory Service when it was formed in October 1946. Since then Mr. Evans has had continuous experience of farming in Wales, having served as county advisory officer in both Radnor and Carmarthen and more recently as deputy director of the National Agricultural Advisory Service for Wales.

Institute of Oceanography, Dalhousie: Prof. Ronald Hayes

The National Research Council of Canada has awarded an annual grant of 90,000 dollars to Dalhousie University, Halifax, Nova Scotia, for the establishment of an Institute of Oceanography. All branches of marine science will come under investigation, and opportunities for work at sea will be provided by the Royal Canadian Navy, the Fisheries Research Board of Canada and other agencies. Prof. F. R. Hayes, who has been appointed director of the Institute, took his doctorate under the late Prof. James Johnstone in the Department of Oceanography, University of Liverpool. As a post-doctoral fellow of the Rockefeller Foundation he worked at the Prussian Marine Station at Heligoland and the University of Kiel. He is at present chairman of the Division of Biological Sciences at Dalhousie University, and a member of the Fisheries Research Board and National Research Council of Canada.

Pressing problems of the Second World War brought a marked impetus to oceanography in Canada. Co-operation then established has continued under a Joint Committee on Oceanography with representatives of the Royal Canadian Navy, the Fisheries Research Board and the National Research Council, as well as Defence Research Board and the Hydrographic Service. Demands for expansion in the various fields brought to notice the lack of adequate provision for the training of recruits and for research unconnected with immediate economic aims. The Committee appealed to the National Research Council, and Dalhousie University proposed a programme of work, for which the present grant makes provision.

Staff appointments at Dalhousie will provide for research and teaching at graduate level in marine branches of biology, chemistry, geology, and physics. The oceanographic programme at Halifax is being expanded considerably. In 1958, the 177-ft. research vessel, *A. T. Cameron*, was brought into service. Built by the Fisheries Research Board, she has five laboratories, will accommodate nine scientists and carries a crew of 25. The Fisheries Research Board Atlantic oceanographic group, previously stationed at St. Andrews, New Brunswick, is moving to Halifax. The Naval Research Establishment has available a corvette, C.N.A.V. *Sackville*, and an algerine, C.N.A.V. *New Liskard*. It is anticipated that a second algerine will be assigned to research work. The Canadian hydrographic service has recently announced plans for a 4,200-ton research ship scheduled for completion in 1961. The vessel will carry a crew of 85 and scientific staff of 15–20. She will have ten laboratories and will carry two helicopters. The double hull will be reinforced for navigation in Arctic waters, and she will be fitted for all types of oceanographic research, including core-sampling of the bottom.

On the Pacific coast of Canada the University of British Columbia has operated an Institute of Oceanography for the past decade. A similar grant from the National Research Council will permit a very considerable expansion of the programme there also.

Appointments to National Research Council of Canada

The following new members of the National Research Council of Canada have recently been appointed: Dr. F. R. Hayes, head of the department of zoology at Dalhousie University, Halifax; Dr. A. D. Misener, head of the department of physics, University of Western Ontario; Dr. J. Unrau, head of the department of plant science at the University of Alberta, Edmonton. The vacancies were created by the retirement of Dr. J. H. L. Johnstone, head of the department of physics and dean of graduate studies, Dalhousie University, and by the deaths of Dr. R. S. Jane, president of Shawinigan Chemicals Limited, and Dr. R. B. Miller, professor of zoology, University of Alberta.

Ciba Fellowships, 1959–60

The Advisory Panel of the Ciba Fellowship Trust has awarded the following Fellowships for the academic year 1959–1960: Dr. M. H. Richmond (University of Cambridge and the Medical Research Council) to study at the University of Copenhagen (microbiology); Mr. V. P. Arya (University of Banaras and of London) to study at the Polytechnic, Zurich (chemistry of natural products); Mr. J. F. Counsell (University of Bristol) to study at the University of Göttingen (physics); Mr. G. L. Duncan (University of Aberdeen) to study at the University of Louvain (polymer chemistry); Mr. K. Jones (University of Sheffield) to study at the University of Heidelberg (organic chemistry); Mr. B. L. Mordike (University of Birmingham and of Cambridge) to study at the Max Planck Institute, Stuttgart (physical metallurgy).

Imperial College of Science and Technology: Fellowships

The governing body of the Imperial College of Science and Technology, London, has made the following elections to Fellowship of the College: Sir Lewis Casson, former student of the City and Guilds College; Sir Graham Cunningham, member of the governing body of the Imperial College; Prof. A. Holmes, professor emeritus of geology in the University of Edinburgh, a former student of the Royal College of Science; Sir Christopher Ingold, professor of chemistry, University College, London, former student and member of staff of the Imperial College; Dr. L. B. Pfeil, director of the Development and Research Department of the Mond Nickel Company, former student of the Royal School of Mines; Mr. R. McKinnon Wood, member of the governing body of the Imperial College.

Television Society Premiums

The Television Society has awarded the following premiums, for outstanding papers read before the London meetings during 1957–58: *The Wireless World* Premium to Mr. B. Overton (Mullard Research Laboratories) for his paper on "Transistors in Television Receivers"; the E.M.I. Premium to Dr. R. Theile (Institut für Rundfunktechnik) for his paper on "Recent Investigations into the Operation of Image Orthicon Camera Tubes"; the *Electronic Engineering* Premium to Dr. J. C. Parr (formerly of Kelvin and Hughes, Ltd.) for his paper on "Some Aspects of Waveguide Technique"; the Pye Premium to Mr. L. J. Griffen (Kolster Brandes, Ltd.) for his paper on "Dressing Television: Cabinet Design"; the Mervyn Premium to Mr. K. H. Smith, (Siemens Edison Swan, Ltd.) for his paper on "Performance of Television Receiver Turret Tuners"; the Mullard Premium to Mr. J. Polonsky (Compagnie Générale de Telegraphie sans Fils) for his paper on "A French Portable Television Camera".

Committee on Chemicals, Oil and Gas from Coal

In the House of Commons on April 16, Mr. J. C. George asked the Paymaster-General what further action the Government proposed to take to investigate possible methods of converting coal into chemicals, gas and oil. Sir Ian Horobin, in a written answer, stated that the Minister of Power has decided, after consultation with Sir Alexander Fleck, chairman of the Scientific Advisory Council, to set up a committee with the following terms of reference: "To review the work that has been done in recent years on the development of processes in which coal is the basic raw material and which will produce marketable products of a chemical or a gaseous or liquid hydrocarbon type; and to make recommendations as to the direction of further research and development work on any such processes which appear to the committee to hold promise of industrial application and as to the type of organization or organizations best suited to carry out such work".

The members of the committee will be: *Chairman*, Mr. A. H. Wilson (managing director in charge of research and development, Courtaulds, Ltd.); *Secretary*, Mr. W. R. G. Bell (Ministry of Power); Mr. M. A. L. Banks (director, B.P. Trading, Ltd.); Mr. Henry Benson (Cooper Brothers and Co.); Mr. H. E. Collins (National Coal Board); Capt. (E) W. Gregson (chairman, Fuel Efficiency Advisory Committee); Dr. R. Holroyd (director, Imperial Chemical Industries, Ltd.); Mr. W. K. Hutchison (chairman, South Eastern Gas Board); Dr. M. A. Matthews (Shell International Chemical Co., Ltd.); Mr. B. E. A. Vigers (Laporte Industries, Ltd.). The committee will be assisted in its work by two assessors: Mr. A. W. Clarke (director, Warren Spring Laboratory of the Department of Scientific and Industrial Research); and Mr. D. A. B. Llewellyn (Ministry of Power).

Manufacture of Polypropylene in Britain

An agreement has been signed whereby Imperial Chemical Industries, Ltd., acquires a licence under the Montecatini and Montecatini/Ziegler U.K. patents covering the production and use of a new polypropylene plastic, originally discovered by Prof. Natta. A new plant to manufacture this plastic ('Propathene') is being constructed at the Wilton Works in North Yorkshire. It is expected to bring the total capacity of Imperial Chemical Industries for polyolefines for 'Alkathene' and 'Propathene' to more than 100,000 tons a year. 'Propathene' is being manufactured at a pilot plant, and arrangements have been made to augment this pilot plant production so that the material will be available commercially from June 1. 'Propathene' is particularly suitable for moulding uses in view of its high rigidity and resistance to temperature. It is also expected to find extensive use in film form and as a general extrusion material.

First Hungarian Atomic Reactor

Hungary's first experimental atomic reactor, which began working on March 25, is a small reactor, of 2 MW. capacity, situated in the Buda Mountains above Budapest. The installation is fully automatic. The Soviet Union supplied plans and a large part of the installation, five Hungarian institutes drew up the final designs and thirty Hungarian establishments took part in the construction of the reactor. It is primarily for research work, and particularly for the training of nuclear technicians. Neutrons obtained from the reactor will be used for experimental examination of the structure of the atomic nucleus, and isotopes will be supplied to industrial, medical and scientific establishments in Hungary. Previously, radioactive isotopes required for therapeutic purposes have been obtained abroad, and short-lived isotopes required for biological experiments could not be obtained at all. The reactor will solve both these problems. Experience gained from the new reactor will be used in the future planning and construction of atomic power stations in Hungary.

The National Engineering Laboratory

The Council for Scientific and Industrial Research has announced that in future the Mechanical Engineering Research Laboratory at East Kilbride, near Glasgow, will be known as the National Engineering Laboratory. This is considered desirable in order to emphasize the national character of the Laboratory, which is part of the Department of Scientific and Industrial Research organization and is financed from public funds: it does not imply any change in the field covered by the Laboratory. A Steering Committee has been set up to look after the programme of the Laboratory, the object of which is to extend knowledge of mechanical engineering science so as to provide industry with the information it requires for the solution of its own ~~particular~~ problems. In order therefore that its work may be focused on practical objectives of real value to industry (which may involve basic or applied research or, in suitable cases, development work), it has been decided that the planning of the Laboratory's activities and the selection of research projects can best be under the control of a small body with a measure of executive authority. The Committee's terms of reference are: (1) to be responsible to the Research Council for the selection of projects and for the allocation of effort to them, within the financial resources allocated to the Laboratory and such other limits as may from time to time be imposed by the Council; (2) to report annually to Council, submitting a research programme for the following year. The Committee, which will be a full committee of the Research Council, is empowered to set up specialist sub-committees to provide technical advice on particular fields of work.

The new Steering Committee will be under the chairmanship of Vice-Admiral Sir Frank Mason, (director of Metal Industries, Ltd., and of H. W. Kearns and Co., Ltd.), who is a member of the Research Council and chairman of the outgoing Mechanical Engineering Research Board. The members of the Committee will be Prof. O. A. Saunders (Imperial College of Science and Technology, London), Norman Elce (director of Metropolitan-Vickers Electrical Co., Ltd.), Dr. D. G. Sopwith (director of the Mechanical Engineering Research Laboratory), Dr. C. M. Cawley (director of Stations and Grants Divisions of the Department of Scientific and Industrial Research). In order to assist the Director as the Laboratory expands and to improve and extend the links between the Laboratory and industry, two deputy directors have been appointed. They are Dr. S. P. Hutton and Mr. F. D. Penny. Dr. Hutton, who is at present head of the Fluid Mechanics Division of the Mechanical Engineering Research Laboratory, will have special responsibilities for fostering closer relationships with industry. Mr. Penny, who is chief development engineer at the Fuel Research Station, will be responsible for the management of the research programme.

Technical Assistance Programmes

At the request of the International Co-operation Administration, the U.S. National Academy of Sciences—National Research Council has undertaken a study of the ways in which science and technology can most effectively be used by the Administration in its assistance programmes for Africa south of the Sahara and north of the Union of South Africa. Leaders in scientific and technological research and African studies have been asked to assist in the evaluation of opportunities for the utilization of research in the fields of public health, medicine, agriculture, natural resources, engineering and education. A final report will be submitted by June 1959. Dr. J. George Harrar, director for agriculture at the Rockefeller Foundation, has been appointed executive director of the study.

Laboratory Equipment in American Schools

Teachers of science in American colleges, universities and non-profit-making organizations have been invited by the National Science Foundation to submit proposals for the construction of better laboratory equipment for use in schools. Under the terms of a new, experimental programme, the Foundation will consider proposals for the design and construction of improved laboratory equipment and for the development of new instructional materials for lecture demonstrations, laboratory and field work for courses at elementary and secondary school, and undergraduate levels in mathematics, astronomy, earth sciences, physical and biological sciences, and engineering. Support will not be provided for the purchase of equipment for renovating school and college laboratories, or for commercial production of equipment or materials.

Nigeria Science Association

As a result of the rapidly increasing volume of scientific work in Nigeria, many scientists have for some time felt the need for a Nigeria Science Association. In October 1957 a meeting was called at the University College, Ibadan, to discuss the matter. After a further meeting in January 1958 it was decided that a Science Association of Nigeria should be formed and should hold its inaugural meeting in December 1958. A steering committee was elected, with Prof. J. Grayson, professor of physiology at University College, Ibadan, as chairman, and Dr. Brian Hopkins, lecturer in agricultural botany at University College, Ibadan, as secretary. The inaugural meeting of the new Association was held at University College, Ibadan, during December 15–19, 1958. At a brief but impressive opening ceremony, which was well attended, the Association was inaugurated by the Hon. Victor Mukete, Federal Minister for Research and Information. The opening ceremony was followed by a conference lasting four days. The first three days were devoted to papers and discussions of general interest and to business meetings, and the last day to specialist sections. Four specialist sections were organized: medical sciences, physical sciences, botany and zoology. At the business meeting, Dr. Eni Njoku, Department of Botany, University College, Ibadan, was elected first president, and Dr. Hopkins secretary. It is hoped that the next conference will be held in Zaria in December 1959.

Frederick Soddy Trust

The first report of the Frederick Soddy Trust (pp. 16. From the Frederick Soddy Trust, 9 The Drive, Hove 3, 1958) includes a full record of grants made up to September 1958 as well as a list of rejected applications, with the view of indicating the principles used in selection. Emphasis is placed on team-work rather than individual work, and on actual study and research in the field. Some details are given of the survey of crofting in South Uist and Benbecula made in 1957; of the proposed study of Corby and of a survey of the parish of Ardington, Berkshire, proposed by the University of Reading; and also of an expedition to the Pyrénées in which a study is to be made of peasant agriculture and its response to a mountain environment; an attempt is to be made to evaluate the extent of possible population movement in the area.

Smoke Control

Under the title "Smoke is Your Enemy" (pp. 8, 1959) the Ministry of Housing and Local Government and the Central Office of Information have prepared a short pamphlet for issue to householders in areas which local councils are proposing to make smoke control areas. The pamphlet explains simply what smoke control will mean to the household, the grants available to the householder and the advantages which smoke control will bring.

Exhibition of German Measuring Equipment

An exhibition of precision measuring equipment, made by Carl Zeiss (Oberkochen) and by M. Hensoldt and Soehne (Wetzlar) and mainly of interest to those working in the fields of engineering metrology and metallurgy, was held during March 9–14, in the showrooms of Degenhardt and Co., Ltd., at 6 Cavendish Square, London. Although the equipment displayed consisted mainly of new versions of well-known measuring and observing instruments, their new look made careful scrutiny necessary in some instances before identification with one or other of their famous prototypes could be made. In general, no claims were advanced for enhanced accuracy of performance over previous attainments, but outstanding improvements have been made in such matters as ease of manipulation of controls and adjustments. These new features considerably reduce the strain of continuous observing and contribute to the readier achievement by the user of the full potentialities of accuracy available in well-designed instruments. Ease of control was especially noticeable in the microscopes, of which the 'Ultraphot' camera microscope and the smaller Zeiss photomicroscope are typical examples; in addition, each is provided with a built-in automatic camera, and exposure time is regulated photoelectrically. The 'Technoscope', a binocular low-power microscope giving five different magnifications for the same working distance, has applications in the laboratory, the engineering workshop and the operating theatre. The range of engineering metrology equipment included the universal, tool-makers', interference and light-section microscopes, optical dividing heads, rotary dividing tables, alignment telescopes and a number of smaller measuring aids and devices.

Organization for European Economic Co-operation Courses on Nuclear Science

The European Nuclear Energy Agency of the Organization for European Economic Co-operation has arranged with the Atomic Energy Research Establishment at Harwell and the Centre d'Études Nucléaires at Saclay (France) for two international courses on nuclear energy. Designed for the teaching staffs of universities and higher technical colleges, each course will accept about fifty applicants, who will have the opportunity to study the latest advances in nuclear science and techniques, to do certain practical work, and to visit nuclear installations. The costs of these courses, both of which will run during July 20–31, are being borne by the European Nuclear Energy Agency, and participants will only be required to pay travel and living expenses.

The Night Sky in May

New moon occurs on May 7d. 20h. 11m. U.T. and full moon on May 22d. 12h. 56m. The following conjunctions with the Moon take place: May 11d. 14h., Venus 7° N.; May 13d. 03h., Mars 7° N.; May 22d. 06h., Jupiter 3° S.; May 24d. 21h., Saturn 4° S. In addition to these conjunctions with the Moon, Mars is in conjunction with Pollux on May 21d. 06h., Mars being 5·3° S., and Venus with Pollux on May 31d. 18h., Venus being 4·2° S. Mercury is too close to the Sun for observation. Venus is an evening star, visible in the south-west after sunset. Conditions are very favourable for observation. Venus sets at 23h. 00m., 23h. 20m. and 23h. 25m. on May 1, 15 and 31, respectively; its stellar magnitude is −3·7. Its distance decreases during the month from 104 to 82 million miles and the visible portion of the disk decreases from 0·734 to 0·607. Mars is moving eastwards among the stars and is in Gemini during May. It sets at 0h. 40m., 0h. 10m. and 23h. 35m. at the beginning, middle and end of the month, respectively. Its stellar magnitude decreases from +1·6 to +1·9 during the month, its distance from the Earth increasing from 173 to 197 million miles. Jupiter rises at 21h. 00m., 19h. 55m. and 18h. 30m. on May 1, 15 and 31, respectively, setting at 5h. 35m., 4h. 35m. and 3h. 20m. It is in Libra. The stellar magnitude of Jupiter is −2·1; its distance from the Earth on May 15 is approximately 410 million miles. Saturn is in Sagittarius, rising at 0h. 00m., 23h. 05m. and 21h. 55m. at the beginning, middle and end of the month, respectively. Its stellar magnitude is +0·5 and its distance approximately 870 million miles. The only occultation of a star brighter than magnitude 6 is that of 115 Tau, on May 10d. 20h. 08·3m. (disappearance at Greenwich).

Announcements

Lord Rothschild is joining the Board of 'Shell' Research, Ltd., on May 1 as part-time adviser on research. He is an assistant director of research in the Department of Zoology, University of Cambridge; until recently, he was chairman of the Agricultural Research Council, a post he occupied for ten years.

Dr. Walter R. Beam, manager of microwave advanced development in the Electron Tube Division of the Radio Corporation of America, has been appointed head of the Department of Electrical Engineering at Rensselaer Polytechnic Institute, Troy, New York.

An English translation of the *Astronomical Journal of the Academy of Sciences, U.S.S.R.*, issued in six parts annually, is being published by the American Institute of Physics in co-operation with the National Science Foundation, under the title *Soviet Astronomy —AJ*. The annual subscription is 25 dollars in the United States, or 27 dollars elsewhere, with special rates for university libraries. Orders and inquiries should be addressed to Translation Journals—*AJ*, 335 East 45 Street, New York 17.

The Glasshouse Crops Research Institute, Worthing Road, Rustington, Littlehampton, Sussex, will hold an open day on June 10. Particulars can be obtained from the Secretary of the Institute.

A conference on the Electric Arc in Welding will be held at the University of Birmingham on June 25. Further information can be obtained from the Secretary, Department of Industrial Metallurgy, University of Birmingham, Edgbaston, Birmingham 15.

An exhibition to commemorate the centenary of the death of Isambard Kingdom Brunel will be held in the main entrance hall of the Engineering Laboratory, Trumpington Street, Cambridge, during May 18–June 19, from 9 a.m. to 5 p.m. on weekdays and 9 a.m. to 12 noon on Saturdays. The exhibition will consist mainly of drawings and photographs of Brunel's principal works.

An exhibition of photometric instruments and microscopes applicable to most industrial processes and almost every branch of medicine, science and research will be held during May 11–21 in ~~the show~~rooms of Degenhardt and Co., Ltd., United Kingdom agents for Carl Zeiss, at 6 Cavendish Square, London, W.1. Throughout the exhibition four technical experts from the Zeiss works at Oberkochen will be in attendance to give advice on the applications of the instruments.

The Editorial Board of the *Journal of Embryology and Experimental Morphology* is sponsoring the fourth of its series of International Embryological Conferences at the Collège de France, Paris, during September 21–24. Details of its organization and scientific programme will be available on June 1 and can then be obtained from Prof. E. Wolff, Laboratoire d'Embryologie Experimentale, 49*bis* Avenue de la Belle Gabrielle, Nogent-sur-Marne, France, or from Dr. L. Brent, Department of Zoology, University College, Gower Street, London, W.C.1, England.

The 1959 conference of the Operational Research Society will be held at the Old Swan Hotel, Harrogate, during June 10–12. The fee is £15. The object of the conference is to provide an opportunity to explore and discuss possible directions for the future development of operational research, particularly in the fields of communications and decision making. Copies of the programme and application forms can be obtained from the Secretary, Operational Research Society, 64 Cannon Street, London, E.C.4.

The fourth International Conference on Ionization Phenomena in Gases will be held in Uppsala, Sweden, during August 17–21. The conference is being arranged by the University of Uppsala in collaboration with the Swedish National Committee for Physics. The main subjects will be: 1, fundamental processes in gas discharges; 2, high-frequency discharges; 3, glow discharges; 4, arc discharges; 5, spark discharges; 6, high-temperature plasmas and controlled fusion; 7, instabilities and oscillations in gas discharges; 8, new methods of measurements. Abstracts, not longer than 350 words, should be received by June 15. Further information can be obtained from the secretary general, Dr. Åke Nilsson, Institute of Physics, Uppsala.

THE COMMONWEALTH ADVISORY COMMITTEE ON DEFENCE SCIENCE

MEETING IN AUSTRALIA

THE Commonwealth Advisory Committee on Defence Science exists to develop the mutual interest of the countries of the British Commonwealth in defence science. Formal meetings are held at two- to three-year intervals in various member countries. Continuity is given to the work, between meetings, by a permanent Working Party located in London. The Working Party is made up of permanent representatives of member countries and is concerned with reviewing progress and planning for future meetings.

To date, five official meetings have been held in addition to a preliminary informal meeting which was held in 1946. Two of the formal meetings have been held in London, one in India, one in Canada and one recently in Australia.

Meetings are attended by senior officers from the Fighting Services and the Defence Scientific Services of the member countries, and it is an indication of the importance attached to the meetings that officers of the highest status are nominated as delegates.

Credit for the creation of the Commonwealth Advisory Committee on Defence Science rests largely with Sir Henry Tizard, who held a prominent position in defence science in the United Kingdom during the post-war period. One of the first acts of the meeting held recently in Australia was to send him a cable of greeting.

In proposing the preliminary or informal Conference which was held in 1946, the United Kingdom authorities suggested that the Conference might consider the distribution of defence research activities throughout the British Commonwealth so as to make the best possible use of the available and potential facilities and staff in each country. This has continued to be a goal for succeeding Conferences.

One of the decisions of the preliminary meeting in 1946 was that there should be close collaboration with the United States of America in the work of the Committee. Its constitution as a Commonwealth body precluded the United States from becoming a member; but a close association has been maintained, and at all meetings of the Committee American observers have been present by invitation and have made significant contributions to the discussions.

The fifth official meeting of the Committee was held in Australia during the period of October 7–28. It was attended by some sixty delegates, approximately forty of whom were from overseas. Countries represented were Australia, Canada, India, New Zealand, Pakistan, South Africa and the United Kingdom, and in addition, a party of observers from the United States of America attended.

On this occasion Ceylon, the Federation of Rhodesia and Nyasaland, Ghana and Malaya were unable to be represented but are being kept informed of the Conference discussions.

On this occasion the general chairman of the meeting was Sir Leslie Martin, defence scientific adviser and chairman of the Defence Research and Development Policy Committee in Australia. Delegations, which were comprised of senior representatives of the Fighting Services and the Defence Scientific Services of the member countries, were led by: Australia, Mr. W. A. S. Butement, chief scientist, Department of Supply; Canada, Dr. J. L. Keyston, vice-chairman, Defence Research Board; India, Brigadier Y. B. Gulati, director of weapons and equipment, Army Headquarters; New Zealand, Dr. C. D. Ellyett, Defence Science Advisers Committee; Pakistan, Dr. Mohammed Afaf, senior scientific officer, Defence Ministry; South Africa, Dr. S. Biesheuval, director, National Institute for Personnel Research; United Kingdom, Sir John Carroll, deputy controller, Research and Development, Admiralty; United States (observers), Mr. J. B. Macaulay, deputy assistant secretary, Research and Engineering, Department of Defense.

In planning the meeting, it was considered important that while full opportunity should be given for adequate Conference discussions, there should also be the opportunity for delegates to obtain a broad picture of defence science activities in Australia. This would also provide the occasion to see something of the geography and general development of the country.

To achieve these objectives, the itinerary provided for arrival of delegates in Sydney, the official opening in Canberra, the main business sessions to be held in Melbourne and Adelaide and for visits to be made to places of scientific service and general interest. This itinerary involved some 3,000 miles travel by air and, therefore, introduced problems of organization, but the results were such that the effort was considered well worth while.

The Conference was opened by the Prime Minister of Australia, the Hon. R. G. Menzies, in Canberra on October 7. In his address, Mr. Menzies directed attention to two points which were important in relation to the social implications of defence science. He commented that, because of the glamour attached to the subject at the present time, there was a tendency for the public to think of defence science as being concerned solely with new and revolutionary developments of a most complex character. While much of the work was, of course, of this nature, he as a layman was most impressed in studying the Conference agenda to find that there was still a great deal of research to be carried out on such everyday items as food, clothing and the weather.

The other point which Mr. Menzies commended to delegates was that defence science was being presented to the public in a way which caused them to feel that these very great efforts were being made solely for military purposes and were, therefore, very largely of a destructive character. He considered that this was far from the truth, and he was of the opinion that there were few defence scientific developments of recent years where the potential application for civil purposes was not of far greater importance than the military application.

The agenda was made up of some seventy technical papers in addition to the reports of the subcommittees on Service psychology and defence food research and the group on agricultural aspects of defence science. The papers were circulated in advance, and at the Conference they were introduced briefly by named delegates and then discussed by the whole meeting. The papers fell largely in the broad fields covered by the above groups and in the fields of career development, telecommunications, tropical warfare, weapons testing, naval research cold-weather operations, effects of high-level noise and the effects of nuclear weapons. However, in addition, there were many individual papers outside these groups.

The subject of tropical warfare was one of special interest to several of the countries represented, in that their territories embraced large areas of tropical terrain. Numerous papers were discussed, ranging from the effect of the environment on the soldier and his equipment, the need for more efficient vehicles and aircraft for use in tropical areas, mental stress under tropical conditions, navigation and communication in the jungle, clearance of vegetation, corrosion in the tropics, etc.

The weapons-testing theme covered the biggest group of papers discussed at the Conference. The subject was interpreted in its broadest sense, aeroplanes, for example, being treated as weapons. This theme was of great interest to Australia, where two of the major defence science activities, namely, the Woomera Missile Testing Range and the Maralinga Atomic Testing Range, are both concerned very largely with the testing of weapons.

In particular, the Woomera project was discussed in some detail. Numerous papers dealing with the equipment of the Range, various aspects of the trials work and the processing of the results were considered. The discussions were supplemented by a comprehensive visit to Woomera, when the facilities were examined in detail and missile trials were witnessed.

While at Woomera, delegates inspected the missile-tracking station which had been established as part of the International Geophysical Year programme.

The visit to Woomera was of particular interest to delegates. The basic conception of this project arose largely from the early discussions by the Commonwealth Advisory Committee on Defence Science, and it was a matter of considerable satisfaction to delegates to see the very tangible result that had been produced. Sir John Carroll, leader of the British delegation, in a public address, referred to Woomera as the outstanding example of defence science co-operation in the Free World.

Because of the importance attached to seeing at first hand something of the scientific work proceeding in Australia, several visits were arranged to scientific and appropriate Service establishments. Included in these were the Aeronautical Research Laboratories, the Defence Standards Laboratories, the Weapons Research Establishments at Salisbury and the testing range at Woomera, the Maralinga Atomic Testing Establishments and the Edinburgh and Woomera Royal Air Force Establishments.

Quite apart from these visits, it was felt that it would be of interest for delegates to be given opportunities of seeing something of the country and of work proceeding in other technical fields. For this purpose, a two-day visit was arranged to the Snowy Mountains Scheme in the south-eastern corner of Australia. This is the largest engineering undertaking in Australia, and can compare in magnitude with the largest undertakings in other parts of the world. Although primarily concerned with the conservation of water by means of river diversion and large-scale storage, it is also a major generator of electric power, having a potential capacity of some 2,000,000 kW.

Numerous opportunities were included in the programme to enable delegates to meet Australians in many walks of life. Delegates were honoured by being entertained to lunch by the Government of the Commonwealth and by being received by the Governors of Victoria and South Australia and by the Lord Mayor of Melbourne. In addition to such official functions, several pleasant informal functions including visits to places of interest and private entertainments were arranged—visits to outback sheep stations and to the Andamooka opal fields.

At the close of the Conference, delegates were unanimous that it was one of the most successful held to date. The tangible results are, of course, a series of recommendations arising from three weeks of intensive discussions. These recommendations are for the guidance of member countries; they will be submitted to the respective governments for ratification, when they will become a valuable guide to defence science policies. The other result of the Conference is the intangible one arising from the friendships established between delegates and the mutual appreciation of the special problems faced by member countries.

LESLIE MARTIN

AUTOMATIC REDUCTION OF GEOPHYSICAL DATA

OVER the past two decades there has been a rapid increase in the use of automatic photographic and electronic techniques for recording experimental results. As a result, the number of measurements made need no longer be restricted by fatigue in the experimenter, and sets of results containing millions of measurements are not uncommon. The rate at which results can be accumulated is now so great that the individuals responsible for setting up the equipment can no longer assimilate the information at the rate at which it is produced. This problem can be overcome to some extent by arranging the programme of analysis in such a way that the reduction of data can be dealt with by semi-skilled staff.

Nowadays even this solution is often inadequate. Not only is it difficult to find suitable staff, but also many of the investigations require the analysis of data on a scale so great as to be beyond the capabilities of a team of individuals. The problem is particularly acute in the field of geophysical research, where very large quantities of results are frequently produced in the course of field work of many kinds.

The automatic reduction of geophysical data was the subject of a Geophysical Discussion organized by the Royal Astronomical Society and held on January 23 under the chairmanship of Sir Edward Bullard. Although the discussion was not primarily concerned with the results of the International Geophysical Year, it was appropriate that it should have been arranged at a time when many individuals must be giving consideration to the study of the unprecedented wealth of new information obtained during the preceding eighteen months.

Sir Edward opened the discussion by pointing out that a single measurement made in each degree square of the Earth's surface would amount to a total of nearly 70,000 readings, and that facilities for handling large numbers of data are almost essential in many types of geophysical work. Even in mobile experiments it was most desirable to arrange, if at all possible, for the results to be recorded directly in digital form. This saved a great deal of time later, since it avoided the need for manual punching on tape or cards, and it frequently made it possible to record data at a rate which would not be possible by other methods.

Sir Edward described his recent voyage in *Discovery II*, in the course of which 90,000 magnetic readings were made near the Azores. The results were recorded directly on punched tape together with other essential information which would be needed during the reduction stage. These included the date, time, records of clock adjustments and range changes and also the ship's position and heading. The programme for the computer was written in such a way that the whole reduction process could be dealt with in one stage. As the principal objective of the work was the study of small irregularities in the Earth's field, it was arranged that the regular component of the field should be removed as part of the computer programme.

Mr. R. H. Merson (Royal Aircraft Establishment) described some investigations of the orbits of artificial Earth satellites. The original aim of the work was to predict the times of future transits in order to enable more accurate positional data to be recorded. Later, it was found possible to gain valuable geodetic information from the results. The approximate size and shape of the orbit are first determined on a desk calculator. This orbit is then adjusted by successive approximations, using a digital computer, to give a least-squares fit with all the available observational information.

The accuracy of the observations is such that it has been possible to derive new values for the coefficients J and D in Jeffreys's expression for the Earth's gravitational potential and to make deductions concerning atmospheric drag on satellites.

The prediction of future transits of Earth satellites requires the rapid processing of incoming data if the results are to be produced in time to be of use. The conditions under which weather forecasts are produced are similar and provide an obvious reason for the use of a digital computer. Mr. G. A. Corby (Meteorological Office) discussed preliminary tests on the preparation of numerical forecasts with the aid of a computer. Barometric pressure and wind-speed measurements are received on tape in a variety of codes at a rate of about 100,000 a day and, to save time, the incoming tapes are decoded in the computer before being used for further processing. The object is to construct a contour map, showing the height of a constant-pressure surface over Europe and the North Atlantic, which accurately represents the observational data. In the least-squares fitting process, it is necessary to minimize the differences between the observed and calculated values of both pressure and wind speed. An additional requirement is that in the determination of the contours for any area, maximum weight must be given to the data from the nearest weather stations. The speed and accuracy with which the forecasts can be produced by automatic methods are satisfactory even though the techniques are still in the development stage.

Mr. M. H. P. Bott (University of Durham) discussed the use of a digital computer for determining the extent of geological formations from surface gravity anomalies. The anomaly due to a model consisting of a series of vertical rectangular prisms of arbitrary depth has been calculated. In the study of a particular formation the procedure adopted is to define a model which leads to the same calculated anomaly as that observed in the area under investigation. Providing the density of the formation is known, the form of the lower surface can be determined uniquely by this method. The technique has been successfully used on the Triassic rocks in Dumfries.

Dr. D. C. Martin (Royal Society) outlined briefly the arrangements which had been made for the collection of data during the International Geophysical Year. Full sets of data would be held in World Data Centres and selected data would be published in Annals of the International Geophysical Year. Although no plans had been made in advance for the automatic processing of the whole of these data, it seemed likely that much of the information would eventually be dealt with by machine methods.

Mr. M. J. Tucker (National Institute of Oceanography) discussed various techniques used in the spectral analysis of geophysical time-series with particular reference to the study of sea waves. Although the analysis can be carried out by deriving the Fourier components of the wave motion, it is often more satisfactory to express the results in terms of the power spectrum or the autocorrelation function.

Proposals for the application of a digital computer to the forecasting of the future behaviour of the ionosphere were outlined by Mr. C. M. Minnis (Radio Research Station). Present intentions are to represent the characteristics of the $F2$-layer in terms of a family of linear functions of solar activity based on all the past observational data. This can be achieved to a satisfactory degree of accuracy if an ionospheric index is used to represent solar activity. The intercepts and slopes which define the linear relations would be stored in a digital computer and those needed to make a forecast for a specified location, season, time of day and level of solar activity would be selected and used in conjunction with other data, in the later stages of the calculations. It is hoped that by this means it will be possible to make forecasts of a more practically useful type than those made using standard manual methods.

In many types of geophysical investigation the use of an automatic digital computer is almost essential if accurate results are to be produced quickly, but it must not be assumed that this is always so. Three speakers referred to work which was being carried out successfully and economically by other methods.

Mr. A. Dennison (British Petroleum Company) described the echo method for the exploration of underground geological formations and the difficulties associated with the usual 'single spot' method of recording the results. Variable-density and variable-area recording had also been tried and the resulting records, when suitably displayed, could give a striking visual picture of the density variations in the underlying structures without any of the computations normally associated with echo soundings.

The analysis of Earth tide records obtained using Milne–Shaw pendulums was explained by Mr. G. W. Lennon (Liverpool Observatory and Tidal Institute), who enumerated reasons why a digital computer would not be appropriate in this type of work. For example, the removal of spurious diurnal and semi-diurnal oscillations would be difficult to programme for a computer, quite apart from the impossibility of producing long records without discontinuities.

Finally, Mr. H. M. Iyer (National Institute of Oceanography) referred to the lack of interest in the study of microseisms. If properly analysed they could yield useful information, and Mr. Iyer described experimental equipment which had recently been developed for the automatic recording of several statistical characteristics of microseisms.

C. M. MINNIS

CHEMISTRY OF CONDENSED TANNINS

THE Plant Phenolics Group held a meeting on "The Chemistry of Condensed Tannins" at Queen Elizabeth College, University of London, on January 6 under the chairmanship of Prof. R. D. Haworth (University of Sheffield). More than sixty members and guests were present.

In the opening paper on "Acid-catalysed Polymerization of Phenolic Compounds", Dr. B. R. Brown (Oxford) briefly summarized past work on this subject and indicated a possible reaction mechanism. *p*-Methoxybenzyl alcohols condense with phenols preferentially in a position *para* to a hydroxyl group to yield diphenylmethanes. A suitably substituted flavan, for example 4′-methoxyflavan, undergoes this condensation via ring-fission. Condensation of 4′-methoxyflavan with 7-hydroxyflavan yields a compound containing two flavan units the structure of which is based upon the known *para*-orientation of these reactions.

The importance of flavan-3 : 4-diols in tannin chemistry has led to an investigation of flavan-4-ol, which condenses with phenols, and with 7-hydroxyflavan yields a flavan 'dimer' isolated as the crystalline acetate.

These condensations, like the acid-polymerization of catechin, require high acid concentrations and it is unlikely that they are involved in the conversion of catechins into tannins in plants. This work aims at establishing the structural details of this condensation and at producing 'polymers' of known structure which can be used for the trial of new degradative methods, which may also be valuable for the degradation of condensed tannins.

Dr. D. E. Hathway (British Leather Manufacturers' Research Association), in a paper entitled "Oxidative Polymerization Mechanisms for Catechins", first briefly reviewed the chemistry of the oxidation of *o*- and *p*-dihydroxy- and *vic*-trihydroxyphenols, which he illustrated by reference to the synthesis of the mould metabolite atromentin, to the formation of purpurogallin and the synthetic melanins, and to the transformation of gallates into ellagates. Possible mechanisms for the oxidation of coniferyl alcohol by laccase, and their relevance to lignin and lignan formation were also discussed.

Studies on the oxidation of (+)-catechin in aqueous and non-aqueous media and on the autoxidation of flavans related to catechin confirm that autoxidation of catechin to a polymer (catechin–tannin) proceeds via the corresponding *o*-quinone followed by intermolecular C—C linkage. The evidence suggests that the most likely linkage is between the 8-carbon of one molecule and the 6′-carbon of the second. The isolation, albeit in small yield, of *m*-hemipinic acid by oxidative degradation of the methylated reduced polymer substantiates this supposition. Further confirmation for the presence of head-to-tail units in the polymer was obtained from a study of the autoxidation and the enzymic oxidation of mixed substrates which resemble the head and tail of (+)-catechin. Enzymic oxidation by mushroom, potato and tobacco polyphenoloxidases proceeds at a faster rate and lower temperature than the autoxidation of catechin, and gives a product precisely similar to the autoxidation polymer.

The heartwood of *Acacia catechu* and the leaves of *Uncaria gambir* contain considerable quantities of (−)-*epi*catechin and (+)-catechin, respectively. The isolation, therefore, of purified tanning fractions in good yield from these sources, with properties similar to the autoxidation and enzymic oxidation polymers of catechin, strongly suggests that these tannins are formed from *epi*catechin and catechin, respectively, by the above mechanism.

Studies on the formation of oak-bark tannin indicate that (+)-catechin, (+)-gallocatechin and leucodelphinidin, which are formed in the leaves, are translocated via the sieve-tube system of the phloem to the cambium, where preferential enzymic oxidation of the pyrogallol phenols occurs. The resulting tail-to-tail polymer is stored in the bark. The remaining tannin action of the bark can be attributed to the occurrence of complex leucoanthocyanins.

In a paper on "Oxidative Condensation in Tea Fermentation", Dr. E. A. H. Roberts (Indian Tea Association) said that, according to Hathway and Seakins, oxidation of (+)-catechin is followed by a condensation between the catechol-*o*-quinone group of one molecule and the phloroglucinol ring of another. If phloroglucinol is added to an enzyme–catechol system, different intermediate- and end-products are formed, indicating a condensation of *o*-benzoquinone with highly active phloroglucinol. Oxidation of pyrogallol to purpurogallin, however, is not affected by the presence of phloroglucinol, which illustrates the very high reactivity associated with the hydroxy-*o*-benzoquinone system. Enzymic oxidations of (−)-*epi*gallocatechin and its gallate are similarly unaffected by the addition of phloroglucinol, but the addition of pyrogallol to these systems yields derivatives of purpurogallin (flavanotropolones). These observations suggest that, following oxidation of the gallocatechins, a condensation takes place between the pyrogallol groups of two separate molecules.

Gallic acid and pyrogallol will not condense to form purpurogallincarboxylic acid unless both substances are oxidized, and this suggests that in the gallocatechin series the condensation takes place between two oxidized molecules. This is supported by the results of a study of the conditions required for the formation of purpurogallin.

The oxidations of (−)-*epi*gallocatechin and its gallate are followed by a linkage of two molecules of the resultant *o*-quinones to form the *o*-quinone of a bisflavanol with the two pyrogallol groups joined by a C—C linkage. Further condensations of this type are excluded on steric grounds, and it is suggested that the primary condensation products undergo either oxidation or reduction. Reduction leads to the formation of one of three possible bisflavanols, whereas oxidation, if a galloyl group is present, could lead to the formation of one of two purpurogallin derivatives. The available evidence supports the view that the theaflavins of black tea have these structures.

Prof. K. Freudenberg (Heidelberg) said that the term leucoanthocyani(di)n was a misnomer for those naturally occuring substances which on treatment with hot mineral acid either under aerobic or anaerobic conditions yield anthocyanidins. He proposed that they be named either 'pre- or pro-anthocyanins'.

Dr. T. Swain (Low Temperature Research Station, Cambridge), in introducing his paper on "Methods for the Investigation of Complex Leucoanthocyanins", also referred to the confusion in the nomenclature of leucoanthocyanins. He suggested that leucoanthocyanins of known structure be called by their systematic name, whereas polymers and co-polymers of hydroxyflavans ('flavols') be known as 'flavolans'. Those flavolans which yielded anthocyanidins on treatment with hot mineral acid would be known as 'flavylogens'. Dr. Swain then described methods for separating polymeric leucoanthocyanins into size groups and for analysis of their end groups.

Mr. W. E. Hillis (Division of Forest Products, Commonwealth Scientific and Industrial Research Organization, Australia), in his paper on the formation of condensed tannins in plants (read by Dr. E. C. Bate-Smith), recalled the probable role of shikimic acid and related alicyclic acids in the biosynthesis of polyphenols. Shikimic acid is present in appreciable quantities in the actively proliferating cambium of eucalypts. A linear relation exists between the amounts of shikimic acid and the weights of enlarging leaves of young *Eucalyptus sieberiana* trees, but this relationship does not hold for the fully-grown leaf; later the amount of shikimic acid in mature leaves diminishes with age. The final stages of the biosynthesis of shikimic acid can occur in the dark, and therefore shikimic acid present elsewhere in the tree need not necessarily originate in the leaves. The distribution of shikimic acid in leaves differs from that of the soluble polyphenols.

Comparative studies of the polyphenols in the cambium, sapwood and heartwood of three *Eucalyptus* species revealed the same general pattern of polyphenols, but shikimic acid was absent from the heartwood and only traces occurred in the developing sapwood. Catechin was less in the heartwood, whereas ellagic and gallic acids increased. On the basis of these facts a possible scheme for the biosynthesis of the heartwood polyphenols was outlined.

Mr. Hillis recalled that he had previously suggested (Society of Leather Trades Chemists Symposium on Vegetable Tannins, 1956, p. 127) that as certain tannins contain appreciable amounts of polymeric leucoanthocyanins, monomeric forms, originating in the leaves, could be the precursors of these substances. Present information, however, favours the formation of heartwood leucoanthocyanins *in situ*. Adaptation of the leucoanthocyanin reaction has enabled the distribution of leucoanthocyanins in plant tissues to be studied by means of coloured photomicrographs.

In dealing with flavans of the resorcinol series in relation to the chemistry of commercially important condensed tannins, Dr. D. G. Roux (Leather Industries Research Institute, Grahamstown, South Africa) said that an examination of previous work on wattle and quebracho extracts indicated that no direct evidence had been provided for the occurrence of catechins or flavan-3 : 4-diols as basic units in the corresponding tannins. The stereochemistry of the recently isolated black wattle catechin (—)-3 : 7 : 3′ : 4′ : 5′-pentahydroxyflavan and (—)-7 : 3′ : 4′-trihydroxyflavan-3 : 4-diol of quebracho heartwood was discussed. The progress of condensation of these compounds in the wood was examined by anthocyanidin formation, by number average molecular weights and by tannin analyses on radial and vertical drillings. These methods afford possible biochemical evidence of the presence of leucoanthocyanidins as intact flavan-3 : 4-diol units in these condensed tannins. The mode of cross-linkage in these condensed tannins must allow for its labile nature.

The chairman encouraged a vigorous discussion at the end of each paper, and among those participating were Drs. White and King (Forestal Central Laboratories), Bate-Smith, Thompson and Whalley.

J. W. T. Seakins

BAMBOOS AND NUTMEGS

TWO important taxonomic studies have recently been published in *The Gardens' Bulletin* (Singapore, 16, 1958), namely, "Bamboos of Malaya" by R. E. Holttum, and "A Revision of the Malayan Myristicaceae" by J. Sinclair.

Holttum has pointed out that the classification of the bamboos, as of other Gramineae, is based on inflorescence, flower and fruit characters; and in so far as such work tends to be done in herbaria, remote from the tropical collecting grounds, much information that would be of great use to the field botanist fails to be included. In fact, what the field botanist mostly sees are bamboos not in flower. Hence the value of vegetative characters, in particular the culm-sheaths, in field observations. This, indeed, is the kind of information possessed by the Malays, by whom the many kinds of bamboo are put to manifold domestic and other uses. Accordingly, in the present very full and informative work, classifications based on both vegetative and reproductive characters are given, together with many excellent line drawings. Botanists and foresters will note with interest an observation on the flowering of bamboos in Malaya. In the equable climate which prevails there, the simultaneous, gregarious flowering of single species in particular areas, sometimes at intervals of several years, which is a well-known phenomenon in India, apparently does not occur. On the contrary, the native Malayan species can continue to grow indefinitely, flower sporadically from time to time, or in some instances, flowering a little almost continuously; the gregarious dying-back after a heavy flowering, as in India, is at most only an occasional feature of the Malayan scene. Among others, an item of considerable interest is a close analysis and comparison of the inflorescences in bamboos and grasses.

In revising the Myristicaceae, Sinclair has pointed out that a regional flora of this group, as, indeed, of any other group, is likely to be unsatisfactory unless it is seen against the considerably wider background of the species present in the whole of the adjacent Malaysian region. Thus, many species formerly considered to be confined to Malaya are now known to occur in Sumatra and Borneo. The difficulties encountered in the systematic treatment of the group are discussed. In the present revision, 53 species, 5 varieties and 1 form are described, whereas, in Ridley's "Flora", the equivalent numbers were 45 species and 4 varieties. Six new species are described. The text is well illustrated with line drawings and with photographs showing bark characters.

AMERICAN ARACHNIDA

The spider family Dictynidæ has only recently been separated from the allied Amaurobiidæ, and its North American species are here revised and described. It is a family of world-wide distribution, with more than thirty genera and three hundred species, predominantly found in the north temperate zone. A dozen are British.

The spiders themselves are small spinners of cribellate webs in a variety of situations, and are unusual in that many species are gregarious, living together in very large numbers. In some areas in the States their thick communal webs choke ornamental conifers and evergreens and so give the spiders an economic importance. Their general habits and mode of life are but little known, and of their courtship and mating even less has been described. As a whole they seem to belong to the spring and summer, at which season alone males are to be found. The females lay only a few eggs, enclosed in lenticular cocoons, which are hung in the webs.

A recent paper by Prof. R. V. Chamberlin and W. J. Gertsch* describes eight American genera and 159 species, 119 of which are placed in the genus Dictyna. All these are fully described with the close attention to detail that modern arachnology requires, and distribution maps are added for many of the commonest species. The paper ends with 47 plates, carrying more than 600 admirable drawings, the work of Miss Marjorie Statham, whose artistry has enriched so many recent publications from the American Museum of Natural History.

It is obvious that this is one of the most painstaking revisions of a family of spiders that has appeared in recent years, and the authors must be congratulated on their achievement. At the same time its true significance can be properly judged only if two other points are mentioned. The first is that the authors themselves describe the revision as "still in many ways a preliminary one", since very large collections of Dictynidæ are now held both in New York and Utah. Here is an indication of the amount of systematic work which even a single family of spiders may involve.

The second point is that this paper recalls others, comparable if not quite so large, lately published in the *Bulletin of the American Museum of Natural History*. Dr. Levi's revision of the genus Enoplognatha and Dr. Muma's survey of American Solpugida are conspicuous examples. These have been supplemented by the smaller but no less desirable publications in the lively series, now some two thousand in number, called *American Museum Novitates*. No fewer than twenty-six of these, all dealing with the systematic side of arachnology, have come into my laboratory during the past few years. Obviously, there is a vigorous and fertile school of arachnology in America, which is taking its share, and more, in the very considerable task of ordering the Arachnida of the world in a coherent, reliable and accurate system. Theodore Savory

OXYGEN AS A PREREQUISITE TO THE ORIGIN OF THE METAZOA

By Dr. J. R. NURSALL
Department of Zoology, University of Alberta, Edmonton, Alberta

During recent years there has been a revival of interest in the problems of the origin of life. This has led to speculation and experimentation, mostly along biochemical and biophysical lines. Less attention has been focused on the problems of the next steps in organic evolution, namely, those attending the diversification of primitive living forms into the kingdoms of organisms recognized to-day.

One of the important questions concerns the sudden appearance of highly organized metazoans in the fossil record. To state this more specifically: Why are there no fossil records of animal life from earlier periods than the Cambrian, the lower reaches of which are characterized by trilobites ? These are far too complex to have been the first animals that appeared on Earth, yet we have no traces of primitive ancestors to them. In Pre-Cambrian rocks there have been found some things that may be fossil sponge spicules and worm burrows, but that is about all. Various theories have been advanced to explain the lack of Pre-Cambrian fossils[1], but none is really satisfactory. However, the general intimation is that a long period of animal evolution must have occurred prior to the appearance of the trilobites, even although no traces remain. Recently Axelrod[2] postulated that the late Pre-Cambrian fauna might have developed in the littoral and immediate shore areas of the seas ; these areas are subject to rapid and drastic erosion, a circumstance which does not favour the fossilization and preservation of their inhabitants. Hence Pre-Cambrian fossils should be rare, but they ought to exist. Axelrod suggests that particular care be used in seeking Pre-Cambrian deposits that can be identified as having originated in shallow seas, and that careful examination be made for the fossil remains of microscopic animals.

I wish to suggest that the lack of faunal remains in Pre-Cambrian deposits indicates the non-existence of a metazoan fauna for the greatest part of that period. I agree with Cloud[3] that there was a rapid (tachytelic) diversification of metazoans in late Pre-Cambrian times, and with Axelrod that the early forms were probably minute. But I wish to argue that the rapid diversification and increase in numbers was brought about by one specific ecological change, namely, by the addition to the environment of a surplus of free oxygen. To support this point of view the following facts and considerations can be marshalled.

In Pre-Cambrian rocks, fossil algæ have been found which precipitated calcium carbonate about themselves in various manners. Of these, *Collenia* is the best-known genus. One supposed alga, *Corycium enigmaticum* Sederholm, is of Archæan age which, if the correlation cited by Rankama[4] is correct, makes the organism 900–1,200 million years old[5]. In addition to such named forms, sporadically occurring carbon deposits have been taken to indicate that life was present and abundant in some Pre-Cambrian times, although of what form or degree of development we do not know.

It is, I think, generally considered that the early atmosphere of the Earth was reducing. Molecular oxygen was foreign to the environment, having been used up in inorganic oxidations. Various chemical reactions have been proposed to explain the advent of oxygen in the atmosphere, but the activities of green plants seem to offer the best explanation of its presence.

The exciting advances made during the past couple of decades in the biochemistry of photosynthesis have demonstrated how chlorophyl molecules could have been built up from inorganic substances through organic substances such as glycine and succinic acid to protoporphyrins and finally complex porphyrin compounds[6]. Photosynthetic reactions could originate anærobically, with oxygen being produced through the photolysis of water.

I suggest the following steps as a possible sequence of events. The primitive forms of life were heterotrophes, absorbing as their nutrients organic substances dissolved in the seas in which they lived. These heterotrophes may have been of several origins and existed in various habitats. Their subsequent evolution would involve considerable 'experimentation' in efficiency of anærobic metabolism. The next step was the development of protochlorophylls by certain types of organisms which would allow the utilization of the energy of sunlight for the reduction of carbon dioxide and its fixation in the form of carbohydrates. The organisms with this ability had thus become autotrophic. If, as has been suggested by several authors, the dissolved organic substances of the seas were becoming depleted after millions of years of forage by heterotrophes, these autotrophes possessed a competitive advantage, namely, freedom from dependence on these substances. They spread rapidly throughout the seas of the Earth. With them went an increasing concentration of an excretory product, oxygen. Oxygen spread through the waters and, by diffusion, into the atmosphere above the waters.

The development of the autotrophes ensured the survival of some heterotrophes as predaceous or carrion-feeding forms. The specialization and spread of autotrophic forms took further millions of years as the process of photosynthesis was improved. This would be the period of development and deployment of algæ. During this time, supported by these plants, there also lived a nondescript assemblage of heterotrophes. The heterotrophes were probably extremely small, perhaps in the form of colloidal aggregates. Of these as yet there has been found no identifiable trace.

Not until the concentration of oxygen in the hydrosphere and atmosphere reached a level at which it became a constant part of the environment did it exert a significant effect on the evolution of the heterotrophes. That is to say, not until there was more than enough oxygen present to take care of the continuing demand of inorganic oxidations was there sufficient to enable organisms to utilize it metabolically. To reach this level of free oxygen required the passage of vast periods of time. Not until the late Pre-Cambrian was this condition reached, but once oxygen became a constant element in the environment, oxidative metabolism with its advantages rapidly became established. Both heterotrophes and autotrophes could partake of these advantages. A variety of primitive forms could respond to the altered environment by using the new, more efficient method of extracting energy from their food. The consequence of such metabolic improvement was the development of metazoan and metaphytic forms through tissue differentiation. It is interesting to note that the fossil record indicates that animals developed earlier into varieties of complex forms than did plants. This suggests that some environmental factor was of more immediate use to animals than to plants. Oxygen was just such a factor.

To summarize, I suggest that (1) the lack of Pre-Cambrian metazoan fossils can be explained primarily by the assumption that there were few metazoans to be fossilized ; (2) the addition of free oxygen to the environment as a constant feature only some 600 million years ago initiated a tachytelic development of metazoans (Urey gives 800 million years ago as the latest time to which a reducing atmosphere could have persisted[7]) ; but the amount of free oxygen required to initiate oxidative metabolism as a prerequisite of life may well have been much more than that required to enter inorganic reactions, so one can picture a period of, say, 200 million years during which there existed barely minimal conditions for partially oxidative life; (3) life spent 1,000 million years or more becoming organized anærobically in the pre-Cambrian seas. This stage ended about 600 million years ago when the concentration of free oxygen reached a level sufficiently high to make it a constant feature of the environment; this enabled some organisms to undertake oxidative metabolism. The subsequent abundance and diversity of metazoan life formed the fossil record as we know it.

I am indebted to Dr. Hans Kalmus for many stimulating and clarifying comments made during the time these ideas were being put in order.

DEDUCTION OF IONOSPHERIC ELECTRON CONTENT FROM THE FARADAY FADING OF SIGNALS FROM ARTIFICIAL EARTH SATELLITES

By W. T. BLACKBAND, B. BURGESS, I. L. JONES and G. J. LAWSON

Radio Department, Royal Aircraft Establishment, Farnborough, Hants

ONE of the most marked characteristics of the radio signals received from the Earth satellites has been the complex fading of the received signal. It is here shown that from a study of the fading it is possible to deduce the electron content for the sample of the ionosphere between the satellite and the receiving station for a large section of the observed trajectory. This gives a sample across the sky, and can give information about the region above the F_2 maximum which is unexplorable by the methods of ionospheric sounding.

These fadings fall into two classes; first, those due to a change in the energy flux at the receiving aerial; and secondly, those accompanying a rotation of the plane of polarization of this energy. These two classes may be distinguished by the comparison of the signals received simultaneously on three orthogonal dipoles. For the first class, the fades will be in phase for all aerials, whereas for the second class there will be relative phase shifts depending upon the direction of arrival of the signal with respect to the dipole axes.

For signals received on a dipole from a satellite moving on a trajectory above an ionized layer, there will be a fading due to the variation in the Faraday rotation of the plane of polarization and also a fading due to the spin of the satellite. It can be shown that the variation in Faraday rotation can arise because of changes in: (*a*) electron content between satellite and receiver; (*b*) intensity of the Earth's magnetic field; and (*c*) angle between this field and the path of the ray in the ionized region.

Hence the rate of fading observed for transits in or above the F-region will be that due to the change in Faraday rotation which may be unmodified, increased or decreased by twice the spin-frequency of the satellite. During many transits a sudden change of twice the spin-frequency was observed in the rate of fading when the reception geometry changed; such a change appears in Fig. 1.

In order to evaluate the electron content corresponding to any part of the trajectory, it is necessary to know the absolute number of rotations of the plane of polarization due to the Faraday effect, as the signal travels from satellite to receiver. In the case of a ray passing normal to the Earth's magnetic field in the ionosphere, the Faraday effect will be very small and to a first approximation may be equated to zero.

This condition will occur at two points on any transit of the satellite, but they may be beyond the observer's radio horizon. However, for observers in Britain and trajectories such as those of the Russian Earth satellites, one of these points may be above the observer's radio horizon when the satellite is at a low angle of elevation north of the observer. The angle of elevation of this point increases as the observer moves farther south towards the magnetic equator. When one of these points is near or above the radio horizon, it is possible to count the number of Faraday rotations of the received signal as the

Table 1

Transit date, time, G.M.T.	n_s (Faraday rotation)		Ionogram		Geomagnetic latitude	$(h_s - h_m F_2)$ km.
	Farnborough	Cambridge	n_s	n_T		
October 18, 1957 03.30		8·2	7·0	4·6	Slough (54°)	40
		5·5	4·8	3·9	Inverness (60°)	10
October 19, 1957 03.30	6·4	6·8	6·9	4·0	Slough	50
	2·8	2·9	3·5	3·5	Inverness	0
November 7, 1957 14.00	31·8	28·2	47·5	14·8	Slough	240
	15·5	16·5	16·5	9·4	Inverness	160

n_T is the number of electrons ($\times 10^{-12}$) in a cm.^{2} vertical column up to the height of F_2 maximum as deduced from ionograms; n_s is the number of electrons ($\times 10^{-12}$) in a cm.^{2} vertical column up to the height of the satellite.

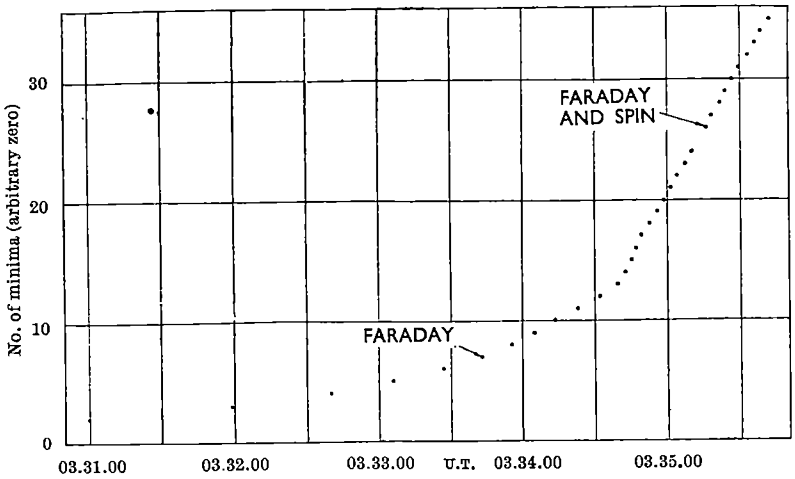

Fig. 1. No. of minima on the fading record taken on October 19, 1957. 40 Mc./s. signal

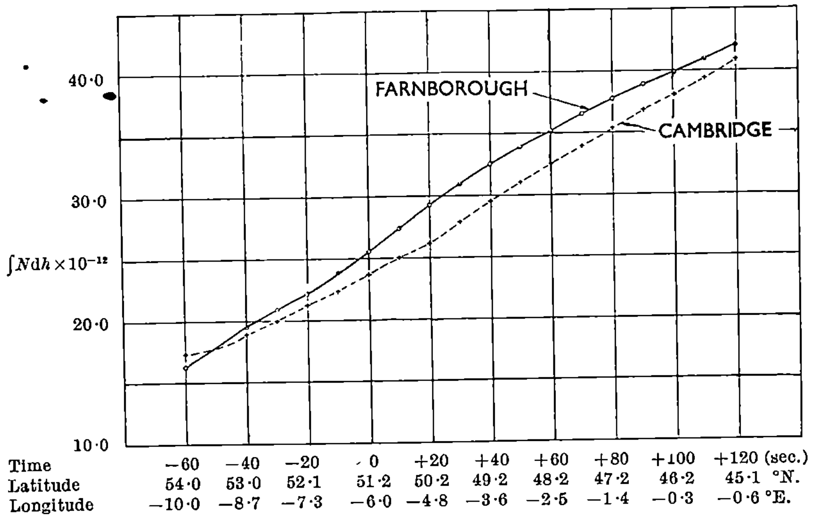

Fig. 2. $\int Ndh$ plotted as a function of position for Farnborough and Cambridge observations

satellite moves through this point to any point on the trajectory. From this number of rotations the electron content of that part of the ionosphere between observer and satellite can then be calculated for various points along the trajectory, and hence the variation of the electron content along a slice of the ionosphere can be determined.

This method has been used to interpret fading records of *Sputniks* 1 and 2 taken at Farnborough and Cambridge when the satellites were nearly overhead and at heights above the F_2 maximum of the ionosphere. The resulting values of electron content could be checked against those deduced from ionograms taken at Slough and Inverness. A comparison of the results is shown in Table 1.

On any one transit the satellite did not pass over both Inverness and Slough. The vertical-incidence results were therefore compared with observations when the satellite was at the corresponding geomagnetic latitude. Geomagnetic co-ordinates were chosen because the data for the critical frequency of the F_2-region over the Earth's surface correlate well with them[1]. Table 1 shows this comparison where n_s, Farnborough and Cambridge, relate to satellite observations, and n_s, Slough and Inverness, to vertical-incidence soundings. At Slough and Inverness n_s was estimated assuming a block of ionization of density NmF_2 extending from the height of the F_2 maximum (hmF_2) up to the heights of the satellite, h_s.

For the 03.30 transits of *Sputnik* 1 on October 18 and 19, 1957, the height of the satellite was only some 50 km. above hmF_2, and the estimated value of n_s (Slough and Inverness) should be only slightly larger than the values obtained from observations of the satellite. This conclusion is supported by the experimental results shown in Table 1. The slight discrepancies that arise can be attributed to errors in height of about 10 km. in either the satellite height or hmF_2.

In the case of the 14.00 transit of *Sputnik* 2 on November 7, 1957, the height of the satellite was well above hmF_2 (about 200 km.). The value of n_s obtained from the observations of the satellite would be expected to be markedly less than that deduced from the vertical-incidence soundings, assuming a block of ionization above hmF_2. The value of n_s (Slough) compared with the satellite observations made at Farnborough and Cambridge is consistent with the above view. In the case of this high transit, the ionosphere explored when the satellite was at the geomagnetic latitude of Inverness was a region south of this latitude. It is shown in Fig. 2 that the electron content decreases towards the north, so that the proper value of n_s (Farnborough and Cambridge), to compare with n_s (Inverness), should be smaller than the value given in Table 1. The satellite observations made on November 7 are therefore consistent with the vertical-incidence soundings.

A comparison of the values of electron content deduced from simultaneous observations made at Farnborough and Cambridge is shown in Fig. 2. At the ends of the transit where the ray paths would pass through the same part of the ionosphere on the way to either base, the measured values are in good agreement. The difference in values in mid-transit probably results from the fact that the rays to Farnborough and Cambridge then follow different paths, with the Cambridge path north of the Farnborough path.

The results presented here show good agreement for observations at different stations, and also agreement with estimates made by an independent method. We conclude, therefore, that the method of analysis is reliable, and further observations along these lines are in progress. The method provides a way of determining horizontal variations in the ionosphere both above and below the maximum of ionization, and has the advantages that the experimental technique and apparatus used are simple, while timing accuracy of about one or two seconds is sufficient.

In carrying out this work we have been helped greatly by the provision of ionograms from the Department of Scientific and Industrial Research stations at Slough and Inverness, and by the staff of the Cavendish Laboratory, who have computed total electron content from ionograms and most generously made available fading records to supplement those taken in our own Establishment. Acknowledgment is made to the Chief Scientist, Ministry of Supply, for permission to publish the communication.

EFFECTS OF WAVE-LENGTH AND TIME OF IRRADIATION ON INTERNODE LENGTH IN *PISUM SATIVUM* AND *TROPAEOLUM MAJUS*

By P. J. M. SALE and Dr. D. VINCE

University of Reading Horticultural Research Laboratories,
Shinfield Grange, Shinfield

THE relative effectiveness of red and blue radiation in controlling photomorphogenic responses of plants has been the subject of some disagreement. Workers at Beltsville have demonstrated a light reaction governing internode length, hypocotyl length, leaf expansion, seed germination, etc., which is mediated through a reversible red/infra-red system[1,2]. However, the effect of blue radiation is far from clear. Downs *et al.*[1], working with the second internode of *Phaseolus*, have claimed that supposed effects of blue radiation can be shown to be due to the relative levels of red and infra-red contamination in the source of blue light. For seed germination, however, an unequivocal effect of blue light, acting in the same direction as infra-red, has been demonstrated by Flint and McAlister[3]. Borthwick *et al.*[4] have suggested that both the infra-red and red-absorbing forms of the red/infra-red pigment have some absorption in the region 400–500 mμ, and that germination is promoted by blue light when the pigment is in the red-absorbing form and inhibited by blue light when the pigment is in the infra-red-absorbing form. The results of the Beltsville group have come mainly from short-term irradiation experiments with etiolated material of *Pisum*, *Phaseolus* and *Hordeum* grown in the dark. Workers in Europe have suggested that the relative effectiveness of blue and red radiation in determining final internode lengths varies according to the experimental technique, particularly the intensity of the light used and the duration of the illumination period[5]. Previous reports[6] from this laboratory have shown, however, that different results are obtainable when different species are given similar conditions of irradiation; shortest internodes occurred in red in *Pisum* and *Calendula*, and in blue in *Lycopersicon* and *Lactuca*. These relative differences in response held over a range of intensities, but very low intensities could not be used for the small-seeded 'blue-sensitive' species. However, the relatively large-seeded species *Tropaeolum majus* has been found to develop shorter internodes in blue than in red light and, accordingly, it has now been possible to measure the responses of the 'red sensitive' and 'blue sensitive' species over a much wider range of irradiances.

The plants used in the investigation were *Pisum sativum* Meteor and *Tropaeolum majus* Double Orange Gleam. The blue and red wave-bands isolated from coloured fluorescent lamps are those described previously[6]; the infra-red was obtained by filtering light from water-cooled 300-watt tungsten-filament lamps through a 1-cm. thickness of 0·1 per cent solution of naphthalene black in water. The wave-bands used are shown in Fig. 1. The red and blue sources were equated on the basis of equal incident quanta. Seedlings were grown at 21° C. and were irradiated from germination with times ranging from 15 min. to 24 hr. in each day. Measurements were made after 14 days; only fully elongated internodes were measured, that is, internodes 2 (first to second scale leaf), 3 and 4 in *Pisum* and internode 1 (soil to first node) in *Tropaeolum*. Results from two experiments at different energy-levels are presented in Fig. 2. The difference in the response of the two species is obvious. For short periods of irradiation red is the more effective in reducing internode extension in both species but, whereas in *Pisum* this effect is maintained for all times of irradiation, in *Tropaeolum* the relative effectiveness of red and blue radiation is reversed for times of irradiation of more than about 1½ hr.

In view of the red/infra-red system cited above, the effect of the near infra-red region on these responses was investigated. Times of irradiation of 4 hr. were chosen to bring the responses into the

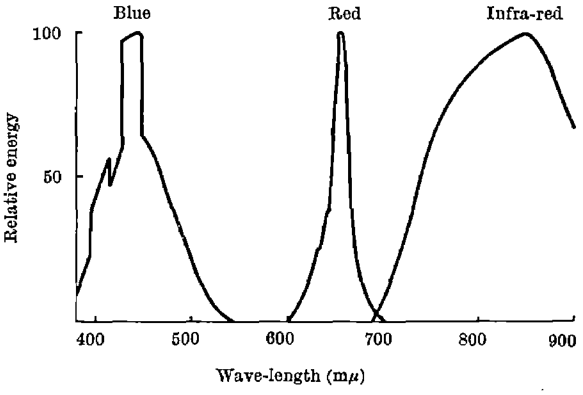

Fig. 1. Relative wave-length distribution of light sources

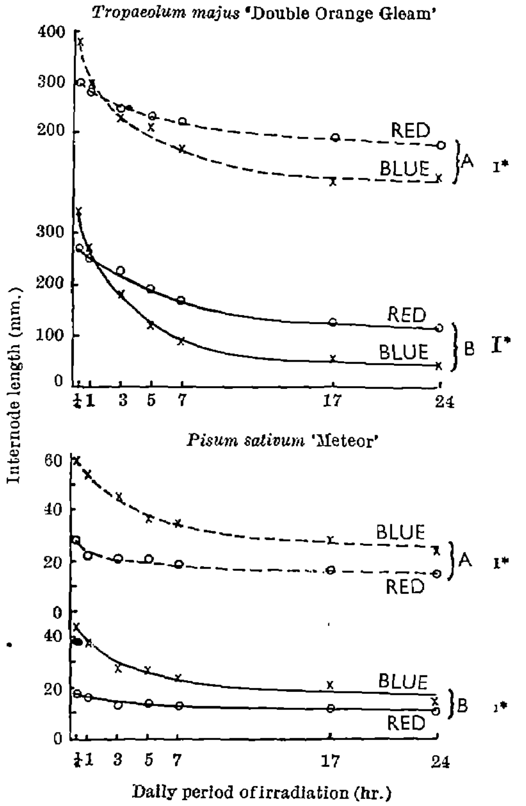

Fig. 2. Effect of irradiation on final internode length. Values for *Pisum* are means for internodes 2–4, for *Tropaeolum* are for internode 1 (see text)

(*A*) Energy-levels { Blue 900 ergs cm.$^{-2}$ sec.$^{-1}$; Red 900 × 0·68 ergs cm.$^{-2}$ sec.$^{-1}$ }
(*B*) Energy-levels × 5 those in (*A*)
Dark values: *Pisum* (*A*) 81·2 mm., and (*B*) 66·0 mm.; *Tropaeolum* (*A*) 556 mm., and (*B*) 593 mm.
* Significant difference at $P = 0{\cdot}05$

region of relatively greater blue effectiveness for *Tropaeolum*. The treatments listed in Table 1 were given every 24 hr. Fully expanded internodes were measured as before after 12 days and the results (mean of two experiments) are given in Table 1. Although differing in their response to blue or red light at these times of irradiation, the two species behaved in essentially the same manner with regard to the effects of one wave-band of irradiation on another. Preliminary treatment with infra-red did not affect the response to either blue or red radiation. The effect of red radiation was almost completely reversed by subsequent exposure to infra-red even with these rather long preliminary exposures to red, when some irreversible growth responses might be expected to have occurred (namely, 4 hr. compared with the usual exposure times to red of 2–5 min. in reversal experiments of this kind). The effect of blue radiation, on the other hand, was only slightly reduced by subsequent irradiation in the near infra-red.

Table 1

Irradiation treatments			Length* of fully expanded internode (mm.)	
4 hr.	4 hr.	16 hr.	*Pisum*†	*Tropaeolum*‡
Infra-red	Dark	Dark	54·0	295·4
Blue	Dark	Dark	27·7	135·5
Infra-red	Blue	Dark	26·4	125·0
Blue	Infra-red	Dark	35·1	156·5
Red	Dark	Dark	13·6	188·0
Infra-red	Red	Dark	15·7	173·5
Red	Infra-red	Dark	42·5	250·2
Blue	Red	Dark	12·5	84·3
Red	Blue	Dark	19·2	123·0
Blue	Blue	Dark	23·8	96·8
Red	Red	Dark	11·9	162·0
Significant difference at $P = 0{\cdot}05$			5·9	20·6

* Means from two experiments.

‡ Internode 1.

Energy-levels { blue, 5,650 ergs cm.$^{-2}$ sec.$^{-1}$; red, 5,650 × 0·68 ergs cm.$^{-2}$ sec.$^{-1}$; infra-red, 4,160 ergs cm.$^{-2}$ sec.$^{-1}$ }

The results presented are in accordance with the hypothesis that there are at least two photochemical reactions controlling internode expansion in these species. The preliminary low-intensity reaction (I) is the well-known red/infra-red reversible reaction established by the Beltsville workers. At longer times of irradiation in *Tropaeolum* a second system (II) becomes more important; this latter system is more sensitive to blue radiation and is not reversible by infra-red. The effects of these two reactions appear to be additive. The presence of the latter system in *Pisum* is indicated by the fact that, following exposure to blue, infra-red has relatively little effect; however, at all the times of irradiation used, internode elongation was more effectively suppressed in *Pisum* by red than by blue light.

The treatment blue–red (Table 1) is of interest since this treatment is more effective than red–blue in causing reduction in internode length, although quantitatively the treatments are the same. In *Tropaeolum*, blue–red is more effective than red–red or blue–blue; in *Pisum*, it is more effective than blue–blue and as effective as red–red. These results can be explained if we assume that, in addition to any effect in 'reaction II', some blue light in the region 400–500 mμ is absorbed by both forms of the red/infra-red reversible pigment, and that its action in this system will depend on whether the pigment is in the red- or infra-red-absorbing form at the start of the blue irradiation (as suggested for the promotion and inhibition of seed germination in lettuce by Borthwick *et al.*[4]). At the end of the 16-hr. dark period most of the red/infra-red pigment will be in the red-absorbing form. Then, in the blue–red treatment, during the blue irradiation there will be a positive effect in 'reaction II' and some of the red/infra-red pigment will be converted to the infra-red absorbing (that is, active form); the subsequent exposure to red will increase this conversion. Conversely, in the red–blue treatment, most of the pigment will be in the infra-red-absorbing form at the end of the irradiation with red light and subsequent exposure to blue will tend to reverse the red effect; there will, however, be a positive effect of blue in 'reaction II'. There is no measurable infra-red contamination present in the source of blue light used in these experiments.

Further experiments are in progress on the time/intensity reciprocity in these responses.

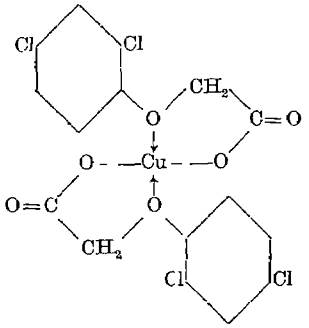
METAL-CHELATING PROPERTIES OF PLANT-GROWTH SUBSTANCES

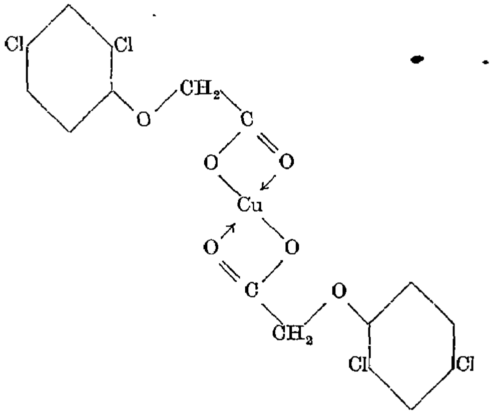
THE suggestion that plant-growth substances act by virtue of their ability to chelate metal ions has received some support from work reported recently by Cohen *et al.*[1] on the formation of copper complexes by indoleacetic acid and naphthalene-α-acetic acid. We wish to report experiments, prompted by their communication, which can be taken to contradict this general hypothesis and disagree in detail with some of the results quoted. We have formed and measured the stability constants of copper complexes of phenoxyacetic acids which have a wide range of growth activity. On the suggested hypothesis the copper complexes should show a similar wide range of stability constants, but we have found them to be indistinguishable.

The copper complexes of the following acids have been studied: 2 : 4-dimethylphenoxyacetic acid, 4-chloro-2-methyl phenoxyacetic acid and 2 : 4-dichlorophenoxyacetic acid, and the analyses of the complexes are shown in Table 1. We have also made measurements of the copper complex of naphthalene-α-acetic acid for comparison with earlier work. Attempts to obtain evidence of the formation of copper complexes in this series with an acid/copper ratio of 1 : 1 failed. The complexes isolated under various conditions were shown to be hydrates of the (2 : 1 : acid : copper) compounds. After dehydration at 140° C. and 0·1 mm., the anhydrous salts were quite stable and did not absorb moisture from the air even after standing for a week. The optical densities of 50 per cent ethanolic solutions containing increasing ratios of acid/copper were determined at wave-lengths where the copper complex absorbs relatively more than the free acids. Plots of optical density against the ratio of acid/copper showed only one break in the curve, at an acid/copper ratio of approximately 2.

Whether or not the materials described above are true complexes in which the organic component is doubly bound to the metal may be questioned. The alternative would be to regard them as simple copper salts. In view of the stability of the anhydrous materials, the formulation as salts would only be valid if the copper had a co-ordination number of 2. The usual co-ordination number of 4 would be consistent with complex formation, involving either one acid and one other oxygen atom as in I or the two acid oxygen atoms as in II. The latter structure has been established for the copper derivatives of fatty acids[2], and we regard it as likely also to be correct in the phenoxyacetic acid series.



(I)



(II)

The stability constants of the copper complexes were determined by pH titration measurements[3] in 50 per cent ethanol. The values in Table 2 were calculated from measurements made in the absence of a strong acid, following what was apparently done by Cohen *et al.*[1]. The *pKc* values differ very little and the copper complex of the acid with the least growth activity is the most stable. Our value for the *pKa* of naphthalene-α-acetic acid (5·76) differs from theirs (4·6), so that the calculated *pKc* which critically depends on the determined *pKa* is also different from their value of 5·4. In so far as our value is higher, it indicates a slightly greater stability for the complex. The presence of a strong acid, however, is theoretically important to the method of pH titration[4] and Table 3 lists the constants determined in 50 per cent ethanol in the presence of a strong acid (10^{-5} *M* nitric acid). It will be seen that the stability constants of the five copper complexes differ by insignificant amounts; indeed, the second figure is scarcely reliable, considering the assumptions made

Table 1

Copper complex	Found C	Found H	Formula for dehydrated complex	Calculated C	Calculated H	Hydrate	M.p. (°C.)
2 : 4-Dimethylphenoxyacetic acid	56·93	5·14	$C_{20}H_{22}O_6Cu$	56·94	5·26	$2 H_2O$	235–6 (decomp.)
2-Methyl-4-chlorophenoxyacetic acid	46·51	3·53	$C_{18}H_{16}O_6Cl_2Cu$	46·73	3·49	$2 H_2O$	247–9 (decomp.)
2 : 4-Dichlorophenoxyacetic acid	38·14	2·25	$C_{16}H_{10}O_6Cl_4Cu$	38·18	2·00	$5 H_2O$	254–6 (decomp.)

Table 2

Copper complex	Stability constants of copper complexes based on measurements in the absence of a strong acid			
	pKa	pK_1	pK_2	pKc
Naphthalene acetic acid	5·76	5·1	4·5	9·6
2 : 4-Dimethylphenoxyacetic acid	4·54	4·6	4·2	8·8
2-Methyl-4-chlorophenoxyacetic acid	4·36	4·3	4·0	8·3
2 : 4-Dichlorophenoxyacetic acid	4·20	4·3	3·8	8·1

pKa is the equilibrium constant of the acid; temperature, 21° C. (pK_1 and pK_2) = pKc, the chelate stability constant of the reaction: $2A^- + Cu^{++}\ (A)_2Cu$; all determinations made in 50 per cent ethanol.

Table 3

Copper complex	Stability constants of copper complexes based on measurements made in the presence of 10^{-5} *M* nitric acid				Growth activity of acid (dose in μgm. needed to give 50 per cent leaf repression)
	pKa	pK_1	pK_2	pKc	
Naphthalene-α-acetic acid	5·75*	5·2*	4·5*	9·7*	0·2±0·1
2 : 4-Dimethylphenoxy-acetic acid	4·53	4·6	3·9	8·5	28±2
2-Methyl-4-chlorophen-oxyacetic acid	4·39	4·4	3·8	8·2	0·15±0·02
2 : 4-Dichlorophenoxy-acetic acid	4·19	4·3	4·2	8·5	0·04±0·005

* Identical values obtained in independent experiments; temperature, 25° C.; all measurements in 50 per cent ethanol.

in calculating the *pKc*. Similar disagreement with the recorded *pKc* for indoleacetic acid – copper complex has been reported recently by Recaldin and Heath[5], although it is not clear what conditions were used for their measurement.

Parallel with the measurements of the stability of the copper complexes, we have made quantitative estimates of the growth-regulating activity of each of these growth substances by the method of Brown and Weintraub[6]. In the last column of Table 3 are listed the quantities of each acid required to depress the growth of the first trifoliate leaf of a *Phaseolus* seedling by 50 per cent. The percentage repression in this test is linearly related to the logarithm of the dose, and the figures for 50 per cent repression are inversely related to the growth activity. It will be seen that 2 : 4-chlorophenoxyacetic acid is almost a thousand-fold more active than dimethylphenoxyacetic acid, though its ability to bind copper is not measurably different.

We therefore suggest that in spite of some evidence in the literature for a relation between metal-complexing capacity and plant-growth activity, the properties by which certain molecules are specifically able to act as growth regulators still remain a mystery.

Our thanks are due to the directors of Imperial Chemical Industries of Australia and New Zealand for permission to publish this communication, and to Mr. D. Fieldhouse, Mrs. M. Markus and Mrs. V. Zangari for technical assistance.

IN putting forward the hypothesis that plant-growth substances might act as such through their metal complex-forming activities[1,2] we did not suggest that no other properties of the molecules concerned could modify their effects upon growth. We specifically raised the question of rate of penetration, and in view of the very various growth-promoting activities of the different agents tried (a variation by no means parallel with their metal-complexing capacities) we had in mind the possibilities that steric hindrance or toxicity might also be modifying the amount of growth promotion obtained.

One might well hesitate to accept that the 'growth-regulating activity' of 2 : 4-dichlorophenoxyacetic acid is almost a thousand times as great as that of dimethylphenoxyacetic acid on the basis of an assay test depending on the inhibition of growth, such as that used by Armarego *et al.* (preceding communication), but other work[3] suggests that their growth-promoting activities in the *Avena* cylinder test are in a similar ratio. Even if this is not, in fact, due to a difference in penetration, the binding of copper or some other metal may yet be concerned with the spatial configuration of the sites favouring one acid rather than the other.

The growth-promoting activity of ethylenediamine tetraacetate has been variously reported as similar to that of indoleacetic acid[1,4], or as much less[5,6], according to the techniques and plant material used; with the strain of wheat used by Fawcett *et al.*[6], and using their technique, we have been able to reproduce their results. However, even if the growth-promoting activity of these two agents be accepted as of the same order of magnitude, the fact remains that their *in vitro* complexing activity differs vastly. It is, in fact, surprising that so powerful a chelating agent as ethylenediamine tetraacetic acid does not disrupt the chemical organization of the cell at many sites; the growth-promotion obtained may be the net result of stimulatory and inhibitory processes due to competition with various chelating agents in some such way as that suggested by Burström and Tullin[7].

Evidence seems to be accumulating that known natural and synthetic growth substances can form complexes *in vitro*[8,9], but more important than this is the question whether they do so in controlling growth in the living plant. Some of the evidence for this was very briefly reported in the communications cited[1,2] and the results of these and other experiments will be published in detail as soon as possible.

LETTERS TO THE EDITORS

PHYSICAL SCIENCES

A New Ionospheric Phenomenon

In recent years, there have been reports[1–4] of sporadic radio-frequency radiation associated usually with auroral activity. However, it has always been difficult to establish an unambiguous identification because similar effects could be caused by man-made noise or interference. The special programme initiated at Jodrell Bank in October 1958 to study these unusual radiations provided a high degree of flexibility by using five separate total-power receivers, all on slightly different frequencies near 80 Mc./s., to monitor continuously various sectors of the sky. At present, two of the aerials are directed at 30° elevation above the northern horizon, one is directed at the zenith, one at 30° above the southern horizon and the other is rotated continuously so that Cassiopeia 23*N*5*A* is always in the beam. Three of the equipments are at Jodrell Bank and the others are on individual sites about 1 km. away. This experimental arrangement allows easy discrimination against localized interference at any one site, and against distant narrow-band radio signals.

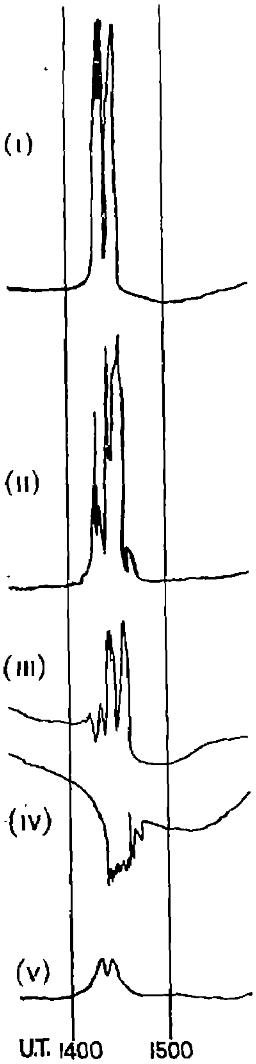

Fig. 1. Records from (I) northerly, (II) northerly (low sensitivity), (III) continuously following Cassiopeia, (IV) zenithal and (V) southerly aerials

Normal records from the equipments show the expected diurnal variation due to the galactic background and, in addition, the southern aerial records radio bursts and noise storms of solar origin. However, during the period January 3–10, 1959, there occurred about ten instances of isolated increases in the noise-level recorded by some of the instruments, together with *simultaneous decreases* in the others[5]. A further very striking isolated event occurred on March 25, 1959, at about 1400 U.T. The records are reproduced in Fig. 1. It can be seen that the northerly channels (i) and (ii) showed very strong enhancements in the signal level. The amplitude of (i) was greater than 150 per cent of the diurnal change in galactic level, and the increase in (ii) was 400 per cent of the diurnal galactic change. The former instrument was driven off-scale while the latter was operating at reduced sensitivity. The apparatus continuously following Cassiopeia (iii) with its aerial directed at this time toward the north-west showed a strong enhancement of approximately 50 per cent of the diurnal galactic range. The zenith instrument (iv) recorded a marked decrease of at least 50 per cent of the diurnal range of galactic intensity, while the south (v) indicated a weak increase of about 25 per cent. Since the back-to-front rejection ratio of the south-looking Yagi aerial is about 1 : 10, it is probable that the apparent southerly increase is spurious in view of the very strong northerly signal. At the time of this event the Sun was actually in the beam of the south aerial, hence one may conclude that direct solar radio-frequency radiation was negligible.

The Jodrell Bank magnetometer revealed a change in the horizontal component of the Earth's field coinciding with these observations. The change of about 50 gammas is the most significant fluctuation in an interval of 4–5 hr. However, the significance, if any, of the magnetic crochet is masked by the presence of other fluctuations of comparable size both earlier and later in the day.

This event, with its simultaneous radio-frequency emission and absorption in different sectors, is more intense than any observed in the January 1959 series. However, it has the same essential characteristics. The suggestion has been made[5] that this phenomenon is caused by passage through the ionosphere of streams of charged particles of very high velocity presumably of solar origin. In the upper ionosphere such particles stimulate the generation of radio-frequency energy while at lower levels the result is a net absorption of the background signal. The absorption mechanism is rather well established, especially in polar regions, and may be attributed to the production of abnormally dense ionization in the lower ionosphere. However, very little is known of processes which can generate radio-frequency noise in our atmosphere. It is believed that the impact of charged particles, both of high velocity and high density, is consistent with the environment for production of Čerenkov-type radiation. Other processes are also being considered.

Events of the type described seem to be rare. It is significant that both the first event of the group in January already reported, and the isolated event of March 25, seemed to be the precursors of a period of intense solar activity with associated terrestrial events such as magnetic storms and auroræ. A preliminary investigation has failed to reveal any unusual solar or other terrestrial effects which may be associated with this phenomenon.

We wish to acknowledge the continued interest and enthusiastic support of Prof. A. C. B. Lovell in this research.

Observations of Intense Ionization of Long Duration below 50 km. Altitude after some Strong Solar Flares

THE existance of ionized layers (the *C*-layers) in the lower and middle atmosphere (between 5 km. and 60 km. altitude) was suggested more than twenty years ago by several authors and such short-range echoes (20–50 km.) have also been reported in recent years. It seems doubtful, however, whether they were produced by ionization[1]. Landmark[2] has recently obtained a few echoes from a height of 65 km., which seem to have been of ionospheric origin. They appeared during periods of strong solar disturbances. Intense ionization at still lower heights was observed four times during the summer of 1958 at Kiruna Geophysical Observatory, Sweden.

The total non-deviative ionospheric absorption of 27·6 Mc./s. radio waves is being measured at the Observatory on a routine basis by means of a so-called 'riometer' (relative ionospheric opacity meter) designed by C. G. Little[3] at the Geophysical Institute, College, Alaska. The riometer is a self-balanced radio noise telescope using a vertical three-element Yagi antenna and having a so-called minimum detector, which makes measurements possible of the cosmic radio-noise level even in the presence of strong interference. The recorded cosmic-noise flux gives a relative measure of the overall absorption in the ionosphere.

On four occasions during the summer of 1958 very strong absorption was observed to start a few hours after the outbreak of solar flares of importance 3+. In three of these cases the maximum day-time absorption[4] exceeded 15 db. At the time of the first observation, July 7, 1958, it was midnight sun in Kiruna, but during the other three periods of observations, starting on August 16, 22 and 26 respectively, the shadow of the solid Earth reached from 62 km. on August 16 to 125 km. on August 26 above the Earth's surface at midnight.

The ratio of negative ion density to free electron number density is a function of the hour angle, as one of the processes determining the ratio is photodetachment of electrons from negative oxygen ions, and thus the absorption is smaller during the night than during the day. The electron affinity of the oxygen molecule is approximately 1 eV., which means that the photons of almost the whole solar emission spectrum have sufficient energy for the photodetachment reaction.

The riometer records for the nights of August 16–17, 22–23, 23–24 and 26–27 were all curves of the type shown in Fig. 1. During the evenings the absorption decreased to a minimal, and almost constant, night-time value, although the shadow of the solid Earth reached levels varying between 44 and 53 km. only (average of four values, 48·3 km.) above the surface of the Earth. Similarly, absorption started to increase again in the mornings when the shadow of the Earth had reached heights between 39 and 55 km. (average of three values, 48·3 km.). During the morning of August 24, a geomagnetic sudden commencement started before sunrise, and therefore no observations could be made.

In two of the seven cases the record is concave upwards (cf. Fig. 1) during the whole transition period between day-time and night-time conditions. In those cases the time of end and beginning respectively of the transition is estimated to be in error by only some ± 3 min. This corresponds to an uncertainty of height of less than ± 2 km. In the remaining five cases the uncertainty is about 5 km.

An explanation of the early arrival of the absorbing layer into the dark region may be that the effective shadow is not that of the solid Earth but of some layer in the atmosphere, for example, the ozonosphere. That explanation can, however, be ruled out by the following facts. It has been found at Stanford, California[5], that the intensity of reflexions on 325 kc./s. tends to increase when the solar rays tangential to the Earth strike the lower *E*-region, and the height of the lowest observed *E*-region reflexion on 100 kc./s. was found to drop appreciably at about the time when the region left the shadow of the solid Earth. These effects are attributed to electron photo-detachment, as in the cases under discussion here. Furthermore, the investigations of the distribution of ozone with height, using the eclipsed Moon as reflecting surface[6], are based on the fact that visible radiation, even in the Chappuis diffuse absorption bands of ozone, penetrates the Earth's atmosphere at the ozone-levels, reaches the eclipsed Moon and is reflected back to the spectrometer on the Earth's night-side. As all radiation of wave-lengths less than approximately 12,000 A. can produce free electrons by photo-detachment from O_2^- ions, the only remaining explanation of the fact that the illumination of the layers above the heights mentioned earlier does not result in any measurable radio-wave absorption in addition to that of the lower layers, seems to be that all but a negligible fraction of the ionization is situated below the heights in question. At such great depths in the atmosphere the absorption coefficient is in fact not increasing with depth as it is in higher levels, due to the fact that for very high values of the electron collision frequency the absorption decreases again. The transition-level is situated between 50 and 60 km.

If one takes into account the possible complete opacity of the lowest few kilometres of the atmosphere, the upper limits of the absorbing layers, given above, are not raised by more than the same small amount (a few kilometres).

The observations reported here support the hypothesis that the ionizing agent on the occasions under discussion was protons, emitted by the Sun during the solar flares (see ref. 4, Hultqvist, B.). The very low recombination coefficients found for this kind of ionization[7] may perhaps also be associated with the

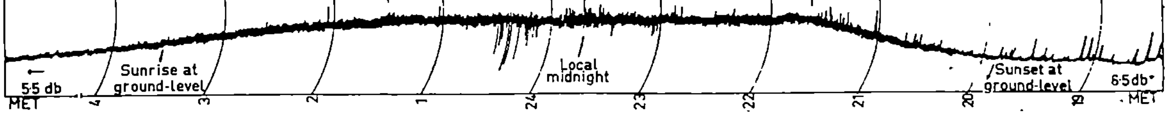

Fig. 1

fact that most of the ionization was situated within the ozonosphere, as is certainly the observed absence of magnetic effects of the ionization.

Radio Reflexions from the Moon and Solar Corona

The ionospheric Faraday effect has recently been used[1,2] to determine the total electron content of the ionosphere. The rotation of the plane of polarization is assumed to be given by:

$$\varphi = 4{\cdot}72 \times 10^4 (f^{-2} B \cos\theta \sec\delta \int_{H_1}^{H_2} N \,\mathrm{d}h) \qquad (1)$$

where the limits of integration correspond to the ionospheric region in which the electron density is large enough to make an appreciable contribution to the rotation (for notation see ref. 2).

On the other hand, the theory of 'whistlers', investigations on the solar corona[3] and also the researches on the first Russian satellite[4] have led to the assumption that there are some hundred electrons per c.c. in the space around the Earth. This necessitates modification of formula (1). If we assume a constant electron density N_0 along the path from the outer ionosphere ($r = r_E + H_2$) to the Moon ($r = r_M$) we have:

$$\varphi = 4{\cdot}72 \times 10^4 f^{-2} \left\{ B \cos\theta \sec\delta \int_{H_1}^{H_2} N \,\mathrm{d}h + N_0 \int_{r_E + H_2}^{r_M} B \cos\theta \,\mathrm{d}r \right\} \qquad (2)$$

or, to a good approximation:

$$\varphi = 4{\cdot}72 \times 10^4 f^{-2} B \cos\theta \left\{ \sec\delta \int_{H_1}^{H_2} N \,\mathrm{d}h + \tfrac{1}{2} . N_0 (r_E + H_2) \right\} \qquad (3)$$

With $(r_E + H_2) = 7{\cdot}4 \times 10^8$ cm. and $N_0 = 10^3$ cm.$^{-3}$, we get $3{\cdot}7 \times 10^{11}$ cm.$^{-2}$ for the second term, while $\int_{H_1}^{H_2} N \,\mathrm{d}h$ is about 100×10^{11} cm.$^{-2}$. Hence we can estimate that in many cases the error introduced by neglecting this second term will not be important, and that, for example, the results obtained on the new F-layer model[5] will not be influenced strongly. But at times of small solar activity, the electron density in the ionosphere will decrease considerably and then we cannot neglect the electrons in the space around the Earth. In these and some other cases (for example, in the polar regions) we must take the revised formula (2) into consideration.

Nature of Fluorescence of Uranium in Fused Sodium Fluoride

Although the property of fluorescence of uranium in sodium fluoride melts has been used to determine uranium quantitatively for the past 25 years, it is not known in what form the uranium exists in these melts. It has been the belief that the fluorescence in fused salts is due to a uranyl compound, but the evidence is not conclusive[1,2]. The intensity of fluorescence of the melts is so sensitive to slight variations in the fusion process that it is necessary to standardize all manipulations to obtain reproducibility. The cause of this sensitivity has not been explained. In an attempt to explain it several different uranium compounds were fused in different atmospheres. The intensities of fluorescence of the melts as well as fluorescence and absorption spectra were measured.

All the uranium compounds used for the experiments were made in this Laboratory. A sample of uranium tetrafluoride was also obtained from Harwell. A very high standard of purity is required as many impurities quench the uranium fluorescence. The sodium fluoride used was 'Baker analysed' and was specially prepared for use on the fluorimeter. This brand of flux was found to be entirely free of sodium carbonate, which is useful at times but not essential, as sodium fluoride–sodium carbonate flux mixtures are often used. Sodium fluoride decomposes during fusion to form small quantities of sodium carbonate when moisture and carbon dioxide are present in the atmosphere[3].

UO_3, U_3O_8, UO_2, UF_4 and $UO_2(NO_3)_2$ were fused with sodium fluoride in air at 1,160° C. and all melts fluoresced strongly. The high fluorescence of UF_4 was unexpected since uranium (IV) compounds have not been known to fluoresce. A test was devised to determine the valency of the uranium in the melt, using the property that cupferron precipitates uranium (IV) but not uranium (VI) in 10 per cent sulphuric acid solution.

Two separate portions of a solution containing uranium (IV) in 10 per cent sulphuric acid were treated with cupferron. Sodium fluoride had first been added to one portion, when a powdery green precipitate had formed. No further precipitation occurred on the addition of cupferron. The uranium (IV) in the second portion was immediately precipitated by cupferron. The sodium fluoride thus reacts with uranium (IV) probably forming a double fluoride, namely, $NaUF_5$ as reported by Katz and Rabinowitch[2]. This compound was found to be non-fluorescent.

This test was repeated using a melt in which uranium tetrafluoride had been fused in air with a low-melting mixture of sodium fluoride and sodium carbonate. When it was dissolved in 10 per cent sulphuric acid no green powdery precipitate settled out and the uranium was also not precipitated by cupferron. From this it was concluded that the uranium is oxidized to the hexavalent state during the fusion process.

The fluorescent species resulting from fused uranium tetrafluoride is therefore not tetravalent as the compounds examined by Zachariasen[2] appear to be.

The fusion of all the uranium compounds was repeated using an argon atmosphere in a tube furnace. All melts were fluorescent but intensities were much reduced. When oxygen was added to the atmosphere the intensities of the argon-fused melts increased in most cases. This seems to indicate that oxygen is required for high fluorescence. The initial fluorescence in argon, particularly of uranium tetrafluoride, appears to be due to the presence of minute quantities of oxygen which diffuse through the walls of the rubber tubing. This is very difficult to eliminate.

When sodium hydrogen fluoride is used as a flux in air with U_3O_8, UF_4 and $UO_2(NO_3)_2$, the usual high fluorescence is obtained, but when fusions are made in argon virtually no fluorescence occurs. This is ascribed to the action of hydrogen fluoride that is evolved from the flux on heating. Katz and Rabinowitch report that very small quantities of hydrogen fluoride are sufficient to prevent the oxidation of $UF_4.H_2O$ during dehydration at 400° C. Hydrogen fluoride also prevents the formation of oxy compounds[2].

The fluorescence spectra of the melts were examined and several variations were measured. The spectrum extended from approximately 5100 to 6500 A. Under certain conditions the lowest band limit ended at 5350 A. The main variations occurred in the violet region where bands appeared and disappeared according to the atmosphere, concentration, time of fusion and rate of cooling.

The spectra of uranyl salts do not vary in this manner. They consist of 6 or 7 bands extending from approximately 4600 to 6400 A. which shift nearer to or farther from the red region, depending on the composition of the salt.

The variation in the spectrum of the sodium fluoride – uranium melts appears to be the cause of the inconsistent intensities. It is not known what this variation is due to but it is suspected that an oxygenated uranium compound, with a variable constitution, is responsible.

The absorption spectra of argon-fused $UO_2(NO_3)_2$, UF_4 and U_3O_8 were measured on the Beckman *DU* spectrophotometer. Clear disks were obtained only when carbonate-free sodium fluoride was used. Melts fused in air became opaque due to the formation of sodium carbonate during fusion. These could not be measured on the spectrophotometer. The spectra of the pale yellow disks were measured against a blank of clear, colourless fused sodium fluoride.

In each spectrum maximum absorption occurred at 290 mμ. Absorption decreased steadily to 410 mμ and levelled off. No further peaks occurred, but each has a plateau from 350 to 360 mμ. Two of these curves are shown in Fig. 1.

Uranyl salts all have absorption peaks[4] in the region 400–500 mμ, while uranium (IV) absorbs in an entirely different manner[5]. The spectra of the fused melts resemble those of diuranates, which absorb strongly at 320 mμ with no further peaks occurring at higher wave-lengths[6].

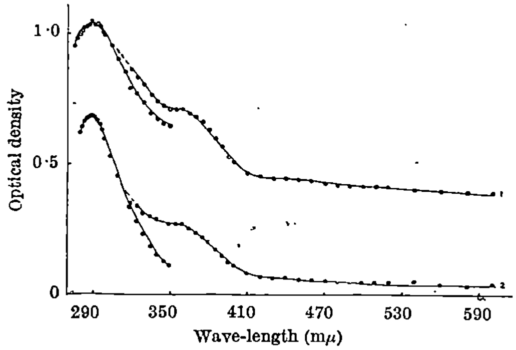

Fig. 1. Top, absorption spectrum of argon-fused uranyl nitrate using hydrogen and tungsten lamp sources; bottom, absorption spectrum of argon-fused uranium oxide (U_3O_8) using the same light sources

Uranyl salts are not stable at high temperatures. When ignited above 350° C. they decompose to form oxides. In the presence of a flux such as sodium fluoride which melts at 997° C. this decomposition must also occur, so that by the time the flux is molten the uranium is probably all present as U_3O_8. This then reacts with or dissolves in the molten sodium fluoride.

The fluorescent species formed does not resemble any of the parent compounds. It appears that any uranium compound can be fused with sodium fluoride at 1,200° C. to form the same or similar species provided that oxygen, moisture and several other constituents are present in the atmosphere. The best atmosphere for this is air.

CHEMISTRY

An Automatically Operating, Coulometric Titration Method for continually measuring Small Amounts of Water in Fluids

SEVERAL batch-wise methods for the determination of small amounts of water are known. However, most of these methods lack general applicability.

In the method described here we have applied the well-known and versatile principle of the Karl Fischer titration. According to this titration procedure, the water to be determined reacts with the so-called Karl Fischer solution, a mixture of sulphur dioxide, iodine, pyridine and methanol. The simplified net reaction can be represented as:

$$SO_2 + I_2 + H_2O \rightarrow SO_3 + 2\,HI \qquad (1)$$

Pyridine and methanol act both as solvents and as complexing agents.

However, contrary to the classical procedure, iodine is generated and measured coulometrically[1]. It is generated by anodic oxidation of a modified Karl Fischer solution, in which the iodine is replaced by hydrogen iodide. At the anode, the following reaction occurs:

$$2\,I^- \rightarrow I_2 + 2e \qquad (2)$$

Automatic and continuous operation is realized as follows: a constant sample stream (for example, an alcohol with a water content less than 2 per cent and a rate of flow ranging from 10 to 100 ml./hr.) is supplied to the coulometric cell (see Fig. 1). In this cell, iodine is generated at the platinum wire electrode, *w.e.* The anode compartment is separated from the cathode compartment by a sloping, sintered glass disk to avoid redox cycles. The magnitude of the generating current i_g is controlled by a combination of an amperometric system and an electronic control system, so that sufficient and no excess iodine is generated for reacting with all of the water entering the cell. In this case the generating current—which can be recorded in simple manner—is a linear function of the water content of the sample. From Faraday's law, 1 μgm./sec. of water supplied to the cell needs a generating current of 10·72 m.amp., provided the current—as well as the titration—efficiency of the electrochemical reaction is 100 per cent. It appears that 100 per cent current efficiency is obtained when the current density does not exceed a critical value, dependent on the conditions of flow. The titration efficiency is—as in the classical titration—not 100 per cent; it is, however, constant, the actual value being dependent upon the composition of the electrolyte.

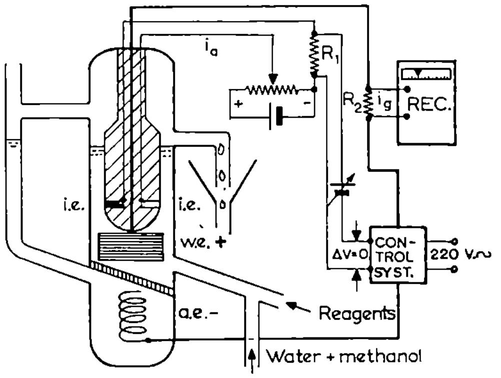

Fig. 1. Diagram of the hygrometer. *w.e.*, Working electrode (anode); *a.e.*, auxiliary electrode (cathode); *i.e.*, indicator electrode

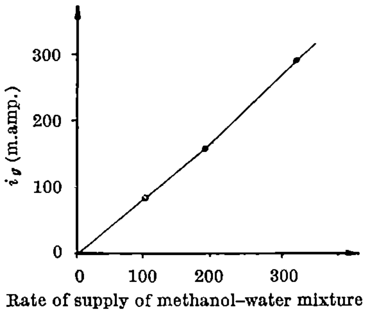

Fig. 2. Generating current i_g (in m.amp.) as a function of the rate of supply of a methanol–water mixture (in arbitrary units)

The amperometric system consists of two platinum electrodes, placed in an equipotential surface and provided with a potential difference of 25 mV. The generating current is so controlled that when the amperometric current i_a exceeds a fixed value of some microamperes (for example, when the water content of the sample decreases), the generating current decreases, etc. Environmental moisture must be excluded rigidly.

A laboratory apparatus built according to the above principles has worked satisfactorily. A typical graph is reproduced (Fig. 2) showing the generating current as a function of the rate of supply of a methanol–water mixture of a definite composition, the speed being expressed in an arbitrary measure.

While preparing this communication, our attention was directed to a recent paper by Meyer and Boyd[1], who have applied the same principle to the batch-wise titration of water.

Molecular Symmetry in *Cyclo*pentadienyl Thallium and Some Related Substances from their Microwave Spectra

It was recently found in this laboratory[1] that the symmetry of *cyclo*pentadienyl nickel nitrosyl is simply and unequivocally shown by its microwave spectrum. We have now applied the same method to demonstrate the symmetries of *cyclo*pentadienyl thallium, *cyclo*pentadienyl manganese tricarbonyl and benzene chromium tricarbonyl. The manganese compound had sufficient vapour pressure at room temperature, but the other materials were studied in a Stark modulation spectrometer operated at about 100° C.

Several transitions of each substance were measured between 20 and 40 Gc./s. The spectra are those of strictly symmetrical-top molecules, with values of B, in Mc./s., as follows: *cyclo*pentadienyl thallium-205, 1465·10 ± 0·05; *cyclo*pentadienyl thallium-203, 1467·98 ± 0·05; *cyclo*pentadienyl manganese tricarbonyl, 826·5 ± 0·5; benzene chromium-52 tricarbonyl, 729·8 ± 0·5. Fine structures were not resolved, but spectra of molecules in excited vibrational states occurred, especially for the carbonyls. For these, B refers to the state showing the strongest absorption, but it is not certain that this is the ground-state. For *cyclo*pentadienyl thallium the lines are sharper, and those due to vibrationally excited molecules occur at lower frequencies than the ground-state absorptions. Separate series of lines due to *cyclo*pentadienyl thallium-205 and thallium-203 are recognized from their pattern and intensities.

The spectra prove that the *cyclo*pentadienyl compounds have axes of C_{5v} symmetry perpendicular to the C_5- and H_5-rings, and passing through the metal atoms. In benzene chromium tricarbonyl the corresponding axis is doubtless one of C_{6v} symmetry but, so far as microwave spectra can show, the symmetry might be merely C_{3v}. The tricarbonyl groups $(CO)_3$, when present, have C_{3v} symmetry about these same axes. The structure of *cyclo*pentadienyl thallium is thus the 'half-sandwich' type favoured by Cotton and Reynolds[2] on the basis of infra-red spectra. The tricarbonyls each have eight structure parameters, and detailed discussion is not profitable; but the values of B are consistent with dimensions expected from the study of related molecules. *Cyclo*pentadienyl thallium has only four structure parameters and, while a complete determination is not yet possible, it is profitable to examine carbon–carbon and carbon–thallium distances which are permitted for all reasonably likely values of the parameters affecting the hydrogen atoms. The simplest preliminary assumption is that the C_5H_5 system lies in one plane. With this assumption only, the distance from the thallium to the centre of the ring is found as 2·41 ± 0·01 A. If, in addition, we take d_{CH} as 1·08 A., we obtain $d_{CC} = 1{\cdot}43 \mp 0{\cdot}02$ A. and $d_{CTl} = 2{\cdot}705 \mp 0{\cdot}005$ A. The errors stated are those which could arise from possible inaccuracy in measurement of the small thallium isotopic shift; effects of changes in zero-point energy have been neglected. A variation in the value assumed for d_{CH} of $\pm$ 0·02 A. leads to additional changes of only $\mp$ 0·004 A. in d_{CC} and $\mp$ 0·002 A. in d_{CTl}. We have also investigated the effects of allowing the CH bonds to be bent out of the C_5-plane. An angular displacement of 5 deg. away from the thallium atom in these bonds leads to an increase of 0·025 A. in d_{CC}, and a decrease of 0·007 A. in the distance from the thallium to the centre of the ring. The distance d_{CTl} is increased by only 0·003 A. Its effect on d_{CC}, and general considerations, suggest that such bending is of small magnitude.

On such a basis, the C_5-ring appears to be similar in size to that found in ferrocene[3], with the possibility of being somewhat larger. The carbon–thallium distance is certainly longer than anticipated by Cotton and Reynolds[2], but there is very little evidence on which to base a prediction. From available data[4], a length of 2·4 A. would not seem impossible for a simple Tl–C linkage, and a greater length is naturally expected in a complex of this type. The distance found, however, coupled with the estimates of overlap integrals by Cotton and Reynolds[2], strengthens the evidence that ionic binding is important in this linkage. From microwave data for metallic halides as ion-pairs, Honig, Mandel, Stitch and Townes[5] tabulate ionic radii for such systems. From these and similar results for the largely ionic gaseous thallous halides[6], the corresponding radius for Tl^+ must be close to 1·0 A. The structure $C_5H_5^-\ Tl^+$ would thus require the $C_5H_5^-$ ion to have an axial radius of about 1·4 A., which does not seem unreasonable. While the structure can scarcely be entirely ionic, a considerable ionic character would not be out of keeping with the findings for the thallous halides.

A detailed report, with fuller discussion, will appear elsewhere. We thank Prof. G. Wilkinson and Dr. M. C. Whiting for gifts of materials, the Royal Society for the loan of equipment and Prof. J. C. Robb for his interest in this project. Two of us (J. K. T. and A. P. C.) acknowledge maintenance grants from the Department of Scientific and Industrial Research.

Molecular Motion of Enclathrated Compounds as studied by Nuclear Magnetic Resonance

It has been known for some time that hydrogen-bonded crystals such as quinol and urea can enclathrate a variety of molecules. Many studies of the structures of clathrates by X-ray diffraction[1–4] and infra-red spectroscopic techniques[5] have yielded little information about the motions of the enclathrated molecules. In special cases, for example, oxygen and nitric oxide enclathrated in quinol, where the trapped molecule is paramagnetic, magnetic susceptibility measurements[6–8] have indicated that the trapped oxygen and nitric oxide molecules behave rather like free gas molecules.

For enclathrated molecules which are not paramagnetic it seemed that nuclear magnetic resonance spectroscopy would provide information about the motion of the trapped compound. We wish to report some preliminary results which we have obtained by studying the proton magnetic resonance signals from certain enclathrated hydrocarbons.

Though a wide range of clathrates are currently under investigation by a variety of methods, we shall give here only some results for magnetic resonance studies on urea hydrocarbon adducts, the hydrocarbon ranging from C_{7-13}, C_{16} and C_{26}. The urea/hydrocarbon adducts were prepared by the addition of the calculated amount of hydrocarbon to a saturated solution of urea in either methanol or in *iso*propanol. The solution was cooled slowly in a lagged Dewar vessel. The largest crystals (about 15 mm. long) were removed and dried. The proton magnetic resonance spectra were measured at 25° C. on a Varian 4300 *B* dual-purpose nuclear magnetic resonance spectrometer with a 12-in. magnet. The spectra were observed at a frequency of 40 Mc./s. and a magnetic field of 9,400 gauss.

All the adducts studied showed similar spectra. These showed a broad resonance line of 6·9–7·1 gauss half-width, mainly due to the protons of the urea cage, and a narrow line of about modulation width due to the protons of the enclathrated hydrocarbon molecules. By using minimum modulation (30 milligauss) and sweeping slowly through resonance (0·09 gauss/min.) the narrow resonance line observed for the urea/hexacosane adduct was estimated to be about 0·25 gauss wide. Fig. 1 shows a smoothed outline of a typical proton magnetic resonance spectrum observed for the hexacosane/urea adduct. Fig. 2 shows the proton magnetic resonance spectrum of hexacosane (m.p. 56° C.) itself under the same conditions. The main resonance peak is approximately 8·0 gauss wide, and the second peak is pre-

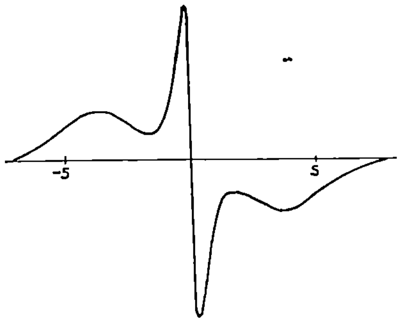

Fig. 1. Smoothed outline of derivative of typical proton magnetic resonance spectrum in *n*-hexacosane/urea adduct at 25° C.

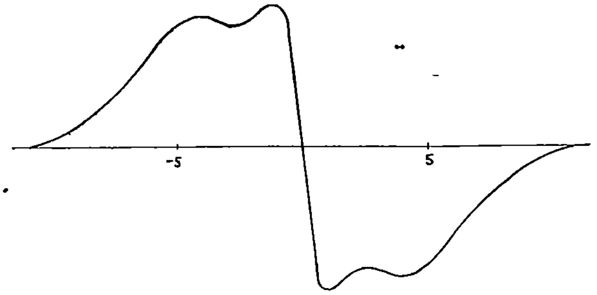

Fig. 2. Smoothed outline of derivative of typical proton magnetic resonance spectrum of n-hexacosane at 25° C.

sumably due to rotation of the terminal methyl groups.

To confirm that the narrow resonance line observed (Fig. 1) for the hydrocarbon/urea adduct was due to the protons of the enclathrated hydrocarbon we studied the proton magnetic resonance spectrum of the n-hexadecane/urea-d_4 adduct. Only a narrow line comparable with that shown in Fig. 1 was observed. This, of course, indicates that the enclathrated hydrocarbon molecules are rotating with some freedom, or executing torsional oscillations, about an axis parallel to the length of the channel in the urea complex.

In contrast to the results given above for urea/paraffin adducts we have observed that the thiourea/*cyclo*hexane clathrate spectrum at 25° C. has a line width of about 1·4 gauss due to the protons of the *cyclo*hexane molecule. *Cyclo*hexane[9,10] itself has, of course, a very narrow proton magnetic resonance absorption peak at 25° C. The broadening we observed when the *cyclo*hexane is enclathrated in thiourea is obviously due to the restriction of the motion of the *cyclo*hexane molecules in the thiourea cage. The crystal structure[4] of the thiourea/*cyclo*hexane clathrate is known. From this it is easy to see how the normal rotations of the *cyclo*hexane molecule at 25° C. are greatly restricted, or eliminated, when this molecule is enclathrated in thiourea.

We are continuing these researches and are determining the line-widths of the proton magnetic resonance signals over a wide range of temperatures. It is hoped that the results will provide useful information concerning the interaction between the matrix and the enclathrated molecules.

This work has been supported by grants from the National Research Council of Canada and we are most grateful to that body for its generosity.

BIOCHEMISTRY

Milk as an Eluant of Polycyclic Aromatic Hydrocarbons added to Wax

PROTEINS in aqueous solution have been demonstrated to elute polycyclic aromatic hydrocarbons from soot particles. The liberated hydrocarbons, although hydrophobic, are retained in solution by the proteins[1]. We wished to determine whether milk, a protein solution, would elute incorporated polycyclic aromatic hydrocarbons from paraffin waxes despite the hydrophobic nature of the hydrocarbons.

Dairy waxes as used commercially to impregnate milk cartons were selected as the vehicle for incorporation of polycyclic aromatic hydrocarbons. It should be emphasized that the elution results reported here relate exclusively to the polycyclic aromatic hydrocarbons which were *added*, rather than to those occurring naturally in dairy wax. However, an analysis of several dairy waxes revealed the presence of a small amount of 1,2,5,6-dibenzanthracene of the order of one part per million in one of them. No 3,4-benzpyrene could be detected at levels as low as 1 in 10^9. The two polycyclic aromatic hydrocarbons chosen for elution studies were 3,4-benzpyrene and 1,2,5,6-dibenzanthracene. Both belong to the group of polycyclic aromatic hydrocarbons usually associated with petroleum derivatives, and their presence in unrefined paraffin waxes from which dairy wax is made is probable. Both these hydrocarbons are potent carcinogenic agents. Our interest in 3,4-benzpyrene is related to its ubiquitous environmental distribution; 1,2,5,6-dibenzanthracene is pertinent because of its demonstration in a particular wax used for coating milk cartons.

Table 1. ELUTION OF ADDED CARBON-14–3,4-BENZPYRENE FROM DAIRY WAX (54 HR.)

	Temperature	
	20° C.	5° C.
Whole milk	94 per cent	63 per cent
Half and half*	91 ,,	43 ,,
Buttermilk	81 ,,	48 ,,
Skim milk	74 ,,	43 ,,

* Equal amounts of milk and dairy cream.

Waxed surfaces containing added amounts of both polycyclic aromatic hydrocarbons were prepared in test-tubes so that a surface area of 26 sq. cm., sufficient to hold 10 ml. of milk, resulted. This represents between 3 and 4·6 times the ratio of waxed surface to milk content found in commercially available milk cartons. The thickness of the waxed layer lining the tubes varied from 75 to 250μ, while in milk cartons thicknesses were 75–100μ. The waxed layers were removed from the tubes by freezing in solid carbon dioxide with subsequent thawing. A stereomicroscope was used for measurement. As anticipated, elution from thin layers regularly occurred more rapidly than from thicker layers.

Four types of milk were selected for study: homogenized milk, skim milk, buttermilk, and a milk-cream mixture obtained commercially as 'half and half'. Differences in fat content and pH in the four milks chosen were expected to yield clues relative to the mechanisms of elution.

Room temperature and usual refrigerator temperature (5° C.) were selected for comparative studies as these are the two commonly encountered in milk

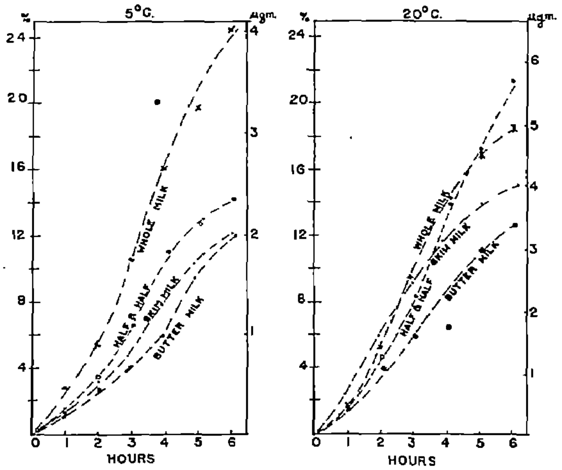

Fig. 1. Elution by milk of 3,4-benzpyrene added to wax

use. In numerous experiments we established that the elution at the two contrasting temperatures of 20° C. (room temperature) and 5° C. (refrigerator temperature) for the various milks was consistent and compatible. We therefore abandoned attempts at attaining identical thickness of wax and concentration of carcinogen when consonant results had been obtained.

The quantity of benzpyrene eluted by milk was determined at hourly intervals for the first 6 hr. of exposure by the difference in intensity of fluorescence between the maximum at 405 mµ and the minimum at 427 mµ. The increase in fluorescence intensity is given in Fig. 1 for each of the milks at room temperature and at 5° C. As we wished to obtain additional information on the completion of elution, the exposure of wax to the particular milks was continued for 24 hr. After the 24-hr. exposure, individual waxes were exposed to fresh samples of each type of milk for an additional 30 hr. At this time, fluorescence could be demonstrated primarily in the upper rim of wax which had not been in contact with the milk. At one extreme, for example, the total amount of benzpyrene retained in the wax after 54-hr. contact with a butter-milk sample was found to be 1·8 per cent. Carbon-14–1,2,5,6-dibenzanthracene was used rather than the unlabelled pure crystalline compound, as the minute amounts of the hydrocarbon used did not possess enough fluorescence energy to be detected.

Elution of benzpyrene and dibenzanthracene was observed in all milk samples studied. Homogenized milk was the best eluant, with the remaining three showing slightly less potency. There was almost total elution of polycyclic aromatic hydrocarbons during a 54-hr. period. The decrease in rate of elution incidental to the depletion of the waxes occurred as expected. At room temperature, the elution was more complete for all four types of samples.

The presence of the polycyclic aromatic hydrocarbons in milk cannot be attributed to a possible solubilization of the wax in milk. This was established by the addition of a strongly fluorescent wax to milk in all experimental circumstances and the subsequent failure to demonstrate fluorescence in the milk.

Milk, independent of its fat content, is an efficient eluting agent and solvent of benzpyrene and 1,2,5,6-dibenzanthracene from hydrophobic wax following the incorporation of these carcinogenic hydrocarbons into wax. This occurs in a manner that is compatible with both the temperatures usually encountered and the duration of contact of milk with the waxed carton.

This investigation has been supported by Grant *CS*–9156 from the Field Investigations and Demonstrations Branch of the National Cancer Institute and Grant *LC*–3 from the American Cancer Society.

Detection of Hydroxyl Groups in Porphyrins and Chlorins

THE behaviour of porphyrin *a* [1] and chlorin a_2 [2], the iron-free prosthetic groups of cytochrome *a* and a_3 and cytochrome a_2 respectively, when run as the methyl esters on paper chromatograms in various solvent systems, suggests that these compounds contain a strongly polar group in one of the side-chains. In the case of porphyrin *a*, the formyl group, which is known to be present, would not alone account for the R_F values obtained.

To test the possibility that the polar characteristics of these two tetrapyrroles were due to the presence of a hydroxyl group in the molecule, the following technique was devised. The porphyrin, or chlorin, was acetylated in a mixture of acetic anhydride and pyridine (1 : 10 v/v) at room temperature overnight, the mixture was then poured into ether and the ether washed well with 0·1 per cent hydrochloric acid followed by distilled water. Paper chromato-

13. 2-α-Hydroxymeso-phaephorbide *a*	0·10	0·78	0·34	0·72
14. Chlorin a_2	0·30	0·65	0·40	0·60

Compounds 3, 7, 8, 9, 13 and 14 were prepared according to known methods, compounds 1, 2, 4, 5, 6, 10, 11 and 12 by methods which will be published elsewhere in detail.

* *This compound contains only one hydroxyl group and one acetyl* side-chain (to be published elsewhere).

graphy of the acetates was then carried out in the chloroform–kerosene, or the propanol–kerosene systems of Chu *et al.*[3], and the R_F values obtained compared with those of the parent compound. These R_F values and those of a number of model hydroxylated porphyrins and chlorins and their acetates are given in Table 1.

The difference between the R_F value of a compound with a free hydroxyl group and that of its acetate is of some value in distinguishing between the presence of one or more hydroxylated side-chains in the molecule.

From the values given in Table 1 it is clear that porphyrin *a*, chlorin a_2, and dioxyprotoporphyrin[4], an irradiation product of protoporphyrin, each contain a hydroxylated side-chain, probably only one in each compound.

Further work is being carried out in this laboratory to determine the nature and position of the hydroxyl groups in these tetrapyrroles.

I wish to thank Dr. R. Lemberg for his interest and advice. This work was supported by a grant from the National Health and Medical Research Council of Australia.

Collagen Content of Normal Connective Tissue, of Tissue surrounding a Tumour and of growing Rat Sarcoma

There have been several studies of the qualitative and quantitative changes produced in different components of connective tissue after treatment of normal animals with carcinogens[1]. However, little attention has been paid to the changes in the connective tissue during the growth of a tumour. This communication reports studies in the collagen content of neoplastic tissue, as well as of the tissue surrounding the tumour, during the development of the neoplasm in rats. The quantities of collagen in subcutaneous tissue taken from the upper part of the abdomen (at a considerable distance from the tumour) were taken as controls.

The experiment was carried out on male and female white rats aged 2–4 months. A fragment of Guérin carcinoma was implanted subcutaneously into the backs of 11 male rats, which formed one group of animals, and a fragment of transplantable sarcoma (42nd passage) first induced by methyl cholanthrene was implanted into the second group of 30 rats comprising both males and females. At different intervals between 3 and 30 days after grafting the tumour the animals were killed, and specimens of the tissues mentioned above were taken for determination of collagen by the Neuman–Logan method[2]. The method was modified by shaking the sample with the same volume of ethyl acetate just before reading the absorption. In this way the coloured impurities originating in either the reagent or the extract were removed. Fig. 1 shows the collagen content of the tissues investigated. Every point represents the mean of three parallel analyses.

Curve *a* shows the dependence of collagen content in the neoplastic tissue on weight of tumour. In the first stage of development of the tumour there is a rapid decrease in the collagen content, after which its level remains unchanged. The levels of collagen in neoplastic tissue of male and female rats bearing sarcoma as well as of males bearing Guérin carcinoma are of the same order. There are no significant differences in the collagen content depending either on the sex of the host or on the kind of tumour.

Curves *b*, *c* and *d* represent determinations of collagen in tissue surrounding the tumour. In contrast to the neoplastic tissue, here the level of collagen depends significantly on the sex of the host. The collagen contents in males bearing sarcoma are almost twice as high as in females bearing the same tumour. Moreover, in males the tissue surrounding the carcinoma contains less collagen than that surrounding the sarcoma.

The line *e* at the top of Fig. 1 represents the arithmetic mean of the collagen determinations; it characterizes the quantity of collagen in the normal subcutaneous tissue of male tumour hosts. It is evident that the collagen-level in normal tissue is higher than that in the tissue surrounding the tumour. This suggests that the subcutaneous tissue reacts to the tumour either by decreased synthesis or by increased catabolism of collagen.

The significant difference in the level of collagen in tissue surrounding the tumour in male and female rats bearing the sarcoma probably is the result of hormonal differences. The findings described above are in agreement with observations on the inhibition of collagen fibril formation caused by the œstrogens[3] and on the decreased collagen synthesis in female rats as compared with males[4].

Glutamic–Aspartic Transaminase of Pig Heart Muscle

THE glutamic–aspartic transaminase of pig heart muscle has been more than 98 per cent resolved into apoenzyme and co-factor by carrying out a differential heat inactivation in phosphate buffer in the course of purification of the enzyme. The apoenzyme has been purified 64-fold, by relatively simple and reproducible techniques. The highest purification factor previously reported[1] for the apoenzyme is 26. The specific activity of the purified apoenzyme compares favourably with that of an electrophoretically homogeneous preparation of the holoenzyme[2]. Cammarata and Cohen's suggestion[3] that purification of the apoenzyme necessarily results in partial inactivation has been disproved, since it is possible to account for all the enzyme activity among the various protein fractions obtained at each step in the purification.

The initial rate of reaction between aspartate and α-ketoglutarate is linearly dependent on the concentration of the purified transaminase only up to 0·004 mgm. protein c.c.$^{-1}$. Above this level the dependence of reaction-rate on enzyme concentration deviates markedly from a linear relation. For the reverse reaction, the dependence of the reaction-rate on enzyme concentration is linear up to 0·01 mgm. protein c.c.$^{-1}$. This phenomenon has been reported for crude enzyme preparations[3,4]; but its consequences have not been considered in any kinetic studies reported hitherto. The following evidence does not support the suggestion[4] that the non-linear dependence of reaction-rate on enzyme concentration is due to the existence in solution of an equilibrium between active and inactive forms of the enzyme. First, the initial rate of reaction is unaffected by reagents known to break down protein aggregates, for example, benzene, ionic detergents and high salt concentrations. Second, when the same low concentration of pyridoxal-5′-phosphate (4γ c.c.$^{-1}$) is used for reactivation of a concentrated and dilute solution of the apoenzyme, equivalent amounts of enzyme taken from the two preincubation mixtures give the same initial rate of transamination on addition to the substrates. This shows that if aggregates are formed at high protein concentrations the aggregation is such that the sites occupied by the co-factor are not masked. Third, the proposed equilibrium between active and inactive forms of the enzyme must be established very rapidly since the observed initial rates of reaction depend only on the enzyme concentration in the reaction mixture and not on the concentration of the enzyme during the period of preincubation with the co-factor.

The variation of the rate of reaction with enzyme concentration is independent of the purity of the enzyme and is unaffected by the addition of a boiled extract of pig heart muscle. It is therefore unlikely that the non-linear dependence of reaction-rate on enzyme concentration is due to the presence of an inhibitor in the original protein extract.

Bonavita and Scardi[5] concluded that the co-factor was attached to the enzyme through the 4-formyl group and that this group was not free to take part in Schiff's base formation with the substrates as suggested by Snell and co-workers[6]. This conclusion was based on the absence of inhibition of transamination by cyanide ions when added, in excess, to the reactivated enzyme followed by 12 hr. dialysis before assay, whereas inhibition did occur when the cyanide ions were preincubated with the co-factor before reactivation of the apoenzyme. In the present work, using cyanide ions and pyridoxal-5′-phosphate in equimolar concentrations, the same degree of inhibition (75 per cent) was observed both when the cyanide ions were added to the reactivated enzyme and when the co factor was incubated with cyanide prior to reactivation of the apoenzyme.

The equilibrium constants for the reaction between the apoenzyme and the two forms of the co-factor have been measured under conditions in which there can be no shift in the equilibrium during the assay of the holoenzyme concentration. Previous determinations of the equilibrium constants[1,7] have been unsatisfactory because such precautions have not been taken. It appears that the true equilibrium constant for pyridoxal-5′-phosphate is some ten times greater than that for pyridoxamine-5′-phosphate.

Braunstein[8] has suggested that the equilibrium constant for the overall transamination reaction depends on the purity of the transaminase preparation used. The equilibrium constant has been determined using a highly purified enzyme solution, and the mean value of K, from some twenty determinations, is 6·50, in close agreement with the value of 6·74 found by Krebs[9] using a crude extract of horse heart muscle.

Deoxyribonucleic Acid Content of the Cell-Nuclei in the Adrenal Medulla after Exposure to Low Temperatures

As has been shown by H. Roels[1] in other endocrine glands, I have found that, in the adrenal medulla of the white rat, there is a correlation between the mean deoxyribonucleic acid content of the nuclei and cell activity. A preliminary communication on this topic[2] reports an increase of the nuclear deoxyribonucleic acid content after stimulation by means of daily injections of insulin, and also an important decrease in the resting gland after bilateral splanchnectomy.

The present communication is devoted to experiments on stimulation of the adrenal medulla by means of exposure to low temperature ; the stress produces hypersecretion of adrenaline.

Five male rats were kept for a fortnight in a refrigerator at nearly 4° C. They were killed, together with five controls. The adrenals and a control testis were simultaneously fixed in alcohol, formol and acetic acid (75 : 20 : 5), dehydrated and embedded. Sections (10μ) of the different objects were mounted on the same slide, in order to obtain homogeneous Feulgen staining. The deoxyribonucleic acid content of the individual nuclei was measured *in situ* by Lison's histophotometrical method[3]. As the deoxyribonucleic acid contents obtained were given in arbitrary units, we used as a standard a 'theoretical diploid value', being half the mean content of 50 spermatocytes I measured in the control testis. The results are summarized in Table 1.

Table 1

	$\bar{x}$	$\log \bar{x}$	s	$s \log \bar{x}$	n
Spermatocytes I	2,663	3·425	0·004	0·006	50
	Theoretical $2s$ value, 1,332				
Controls 284	1,308	3·116	0·046	0·006	50
285	1,366	3·135	0·067	0·009	50
286	1,200	3·079	0·045	0·006	50
287	1,210	3·082	0·055	0·007	50
288	1,267	3·102	0·053	0·007	50
Pool	1,268	3·103	0·052	0·003	250
Cold-treated 289	1,469	3·167	0·043	0·006	50
290	1,426	3·154	0·039	0·005	50
291	1,389	3·142	0·042	0·005	50
292	1,372	3·136	0·034	0·004	50
293	1,446	3·160	0·039	0·005	50
Pool	1,414	3·150	0·041	0·008	250

As the different individual deoxyribonucleic acid contents of the nuclei present a log-normal distribution, the statistical computations are made using the logarithms of these values.

Comparing cold-treated animals and controls, it is clear that the stimulation of the adrenal medulla is accompanied by an increase in the mean deoxyribonucleic acid content of the nuclei, which for the pooled results reaches 11·4 per cent ($t = 7{\cdot}0$; $P < 0{\cdot}001$).

This investigation was aided by a grant from the Belgian F.N.R.S.

New Types of Salting-out Paper Chromatograms of Antibiotics

ACCORDING to Miyazaki, Omachi and Kamata[1], antibiotics can be grouped according to their salting-out chromatograms. Pure antibiotics and materials containing antibiotics were examined by the aid of ascending paper chromatography. As irrigation solvents in each case and with each antibiotic, distilled water and rising concentrations of ammonium chloride (0·5, 1, 2, 3, 5, 10, 20 per cent and saturated) were used. Location of the spots of the antibiotics, that is, the R_F values, were ascertained bio-autographically.

Antibiotics were divided into four groups. In those of group *A* the R_F value is not correlated with the concentration of the ammonium chloride solution, identical values being found at all concentrations and in distilled water. To this group belong penicillin, grisein, chloramphenicol, aureothricin, and the special substance 2. In group *B* are those antibiotics which have an R_F value 0 in distilled water, and increasing R_F values with increasing concentrations of ammonium chloride. They are : streptomycin, streptothrycin, luteomycin, fuscomycin, xanthomycin and flaveolin. Group *C* is different from group *B*, displaying the highest R_F value in distilled water, and lowering of the values with increasing concentration of the solution of ammonium chloride. Members of this group are : actinomycin and griseoflavin. Group *D* consists of antibiotics which do not display any movement whatever in an irrigating solvent from the starting point ; eventually increased tailing tendency was observed with higher concentrations of the solutions of ammonium chloride. Aureomycin and terramycin are members of this group.

These results obtained by Miyazaki *et al.* have been confirmed by my experiments with salting-out paper chromatography of antibiotics. Moreover, I have been able to show the existence of other types of salting-out paper chromatograms of antibiotics with antibacterial action, of actinomycetal origin.

In group *E* are antibiotics which have an R_F value 0 in distilled water, and an initial increase with rising concentrations of the solution of ammonium chloride, the maximum being (R_F = nearly 1) in 5 per cent ammonium chloride. Thereafter a decrease occurs, as shown in Fig. 1. The line connecting the different R_F values is of the shape of a truncated parabola. This type of paper chromatogram was

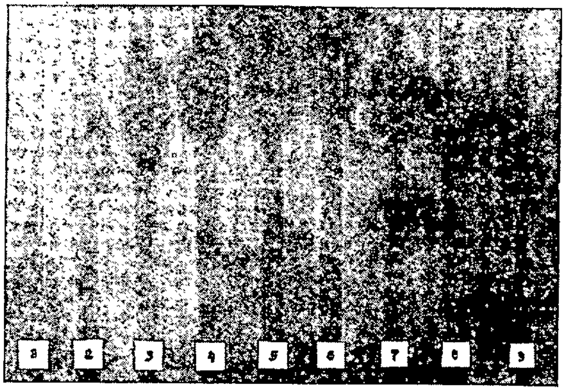

Fig. 1. The salting-out paper chromatogram of erythromycin. 1, Distilled water ; 2, 0·5 ; 3, 1 ; 4, 2 ; 5, 3 ; 6, 5 ; 7, 10 ; 8, 20 per cent ; and 9, saturated ammonium chloride solutions

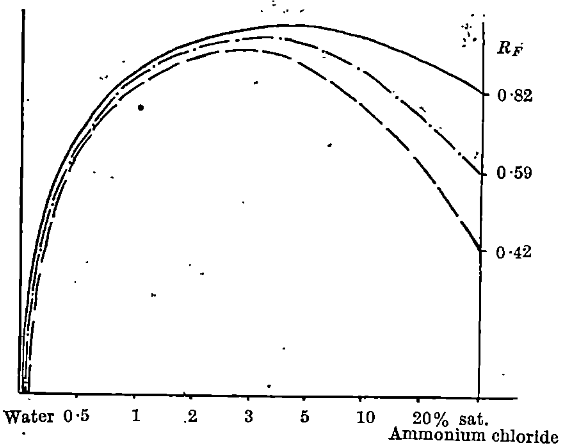

Fig. 2. Curves of the salting-out paper chromatograms of three macrolides. ———, Oleandomycin; –·–·–·, erythromycin; – – – – – –, carbomycin

found in the well-known macrolides (for example, oleandomycin, erythromycin and carbomycin). Within the group, further differentiation of these three macrolides was possible. The curvature of the truncated parabola—best demonstrated by the R_F value in saturated solution of ammonium chloride—is different in these three compounds. The slightest curvature occurred with oleandomycin, the R_F value in saturated ammonium chloride being 0·82; the maximal one with carbomycin (under identical conditions the R_F was 0·42). A midway position is occupied by erythromycin (R_F value being 0·59), as shown in Fig. 2. Obviously, the curvature of the truncated parabola is proportional to the molecular weight of these three macrolides. With the least curvature for oleandomycin is associated the least molecular weight (689); with the greatest curvature of carbomycin the highest one (844). As regards molecular weights, erythromycin is again midway between these (733).

At present, only one antibiotic can be placed in group *F*. This is desertomycin, produced recently by Úri *et al.*[2]. The characteristic feature of the salting-out paper chromatogram is the 0 value of R_F in distilled water. A rise of the R_F values is associated with increasing concentration of ammonium chloride up to 3–5 per cent; thereafter, however, R_F values decrease, and the value $R_F = 0$ is associated with saturated ammonium chloride solution. This type of chromatogram is shown in Fig. 3. By connecting the single R_F values, a paraboloid curve is obtained. This seems to unite groups *B* and *C* of Miyazaki *et al.*, the main representatives being streptomycin with primarily antibacterial activity, and actinomycin which is endowed with a cytostatic effect also. Desertomycin exerts an antibacterial as well as a cytostatic activity, as I have shown. Since this type of salting-out paper chromatogram has not been reported among antibiotics hitherto studied, in addition to its other characteristics, this feature is further proof that desertomycin is a new antibiotic.

ANIMAL PHYSIOLOGY

Thyroxine-releasing Effect of Salicylate and of 2,4-Dinitrophenol

THE fact that salicylate increases the oxygen consumption in man was first observed by Denis and Means[1] in 1916. This observation has since been corroborated by several other investigators[2]. The oxygen consumption of tissues removed from animals treated with salicylate is likewise increased[3].

Coincident with the increase in metabolic rate, there is a decrease in the protein-bound iodine of the serum, and the fractional rate of disappearance of injected radiothyroxine from the circulation increases[2]. Furthermore, salicylate causes a reduction in the uptake of radioiodine by the thyroid[2], but the uptake is increased after stimulation by thyrotropin[4]. Similarly, 2,4-dinitrophenol can induce a rise in basal metabolic rate and a coincident fall in protein-bound iodine in the serum[5]. In experiments with laboratory animals, it has been found that dinitrophenol may reduce the uptake of iodine-131 by the thyroid[6]. The mechanisms by which salicylate and dinitrophenol act have not been elucidated.

All these observations could, however, be explained by an increase in the plasma level of free thyroxine, that is, thyroxine not bound to protein. It is presumably the concentration of free thyroxine which controls the quantitative biological effect of the thyroid hormone[7].

Austen, Rubini, Meroney and Wolff[2] found no change in the concentration of thyroxine-binding protein after salicylate administration. They concluded that the effects of salicylate could not be due to a change in the binding of thyroxine.

I have recently described a method for direct determination of free plasma thyroxine[8] which has permitted a renewed investigation of this problem.

The interaction between thyroxine (*Tx*) and thyroxine-binding protein (*P*) may be expressed by the reaction scheme:

$$Tx + P \rightleftarrows TxP$$

where the equilibrium is displaced so far to the right that less than one-thousandth of the total thyroxine is free.

Application of the law of mass action gives:

$$[Tx_f] = k\frac{[PBI]}{[P_{\text{unsat.}}]} \tag{1}$$

where Tx_f denotes free thyroxine and $P_{\text{unsat.}}$ unsaturated thyroxine-binding protein. On the assumption that all organic iodine present is in the form of thyroxine, TxP has been replaced by PBI in the equation.

It should thus be possible to obtain an estimate of $[Tx_f]$ if the unsaturated protein could be determined in addition to the protein-bound iodine, which may be analysed chemically.

If a tracer dose of radiothyroxine ($Tx^{131}I$) is added to a sample of serum, the following relationship will be valid after equilibrium has been established:

$$\frac{[Tx^{131}I_f]}{[Tx_f]} = \frac{[PB^{131}I]}{[PBI]} \tag{2}$$

When the expression (1) for $[Tx_f]$ is inserted in this equation, we obtain:

$$\frac{[Tx^{131}I_f]}{[PB^{131}I]} = \frac{K}{[P_{\text{unsat.}}]}$$

Thus it is seen that the denominator of the fraction in equation 1 can be calculated by determining the fraction of the added quantity of radiothyroxine that is present in the free state. ($[Tx_f]$ can also be calculated directly from equation 2.)

The determination was carried out as follows. A 'Plexiglas' vessel consisting of two separate, identical parts was assembled with a 'Cellophane' membrane between the two halves. In one of the chambers thus formed was placed 10 ml. of serum, to which radiothyroxine was added (chamber *A*). In the other chamber was placed 10 ml. of serum to which the same quantity of normal thyroxine was added (chamber *B*). The assembly was incubated in a constant-temperature bath with adequate stirring of the solution containing the radiothyroxine.

The free $Tx^{131}I$ passes through the membrane at a rate proportional to its concentration. During the first 24 hr., two samples of 4 ml. or three of 3 ml. were withdrawn from chamber *B*. At the same time an equal volume was removed from chamber *A*.

Since the $Tx^{131}I$ employed contained some inorganic iodine-131, the samples had to be washed carefully[9], after which the content of $Tx^{131}I$ was determined in a well-type scintillation counter. The result is expressed as per cent of the total $PB^{131}I$ in chamber *A*. Details of the experimental procedure are described elsewhere[8].

The results are shown in Fig. 1 and in Table 1.

Table 1. Effect of Addition of 2,4-Dinitrophenol

2,4-Dinitrophenol added (mgm./100 ml.)	Percentage increase of free thyroxine
0·5	9
1·0	18
3·0	25
5·0	38

As can be seen from Fig. 1 the salicylate evidently causes a substantial increase in the amount of $Tx^{131}I$ passing through the membrane. According to the above considerations this must be due to an increase in free thyroxine.

The thyroxine-releasing effect of salicylate and of dinitrophenol is probably a result of binding of these substances to some of the thyroxine-binding sites of the plasma proteins. Whether this is true only of the albumin or whether it also applies to the specific thyroxine-binding protein cannot be decided on the basis of the present investigations.

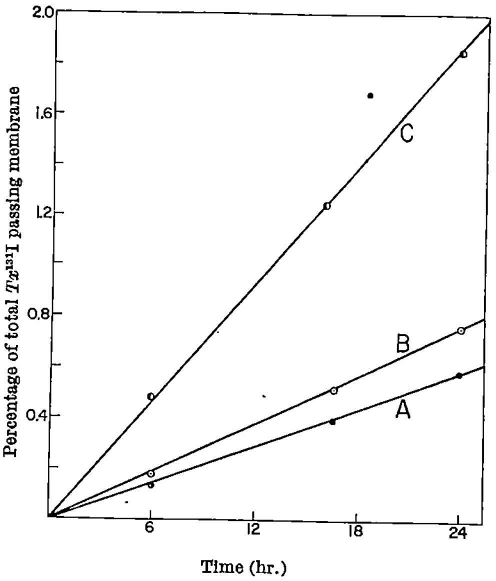

Fig. 1. *A*, Amount of $Tx^{131}I$ passing through the membrane at various times; *B*, effect of 10 mgm. sodium salicylate per 100 ml. added to both chambers; *C*, as *B* with 50 mgm. sodium salicylate

After administration of an ordinary dose of salicylate, the level in the plasma is in the range[2] 20–50 mgm./100 ml. Thus the above experiments can explain the rapid calorigenic action of salicylate, and also the fact that the action is transient. The increase in free thyroxine explains the increased fractional rate of disappearance of injected radiothyroxine and the fall in *PBI*. Furthermore, the fall in the uptake of radio-iodine by the thyroid, and the increase after administration of thyrotropic hormone, may be explained by the increase in free thyroxine.

Thus, the experiments definitely support the idea that it is the free plasma thyroxine that regulates the pituitary effect on the thyroid.

The dose of dinitrophenol that causes a calorigenic effect in man is 200–300 mgm./24 hr. period. This dose may well give rise to plasma concentrations of dinitrophenol within the concentration-range in Table 1. Possibly dinitrophenol also has a direct effect on the uncoupling of oxidative phosphorylation[10]. The effect may even be a more important factor in its calorigenic effect. However, the fall in protein-bound iodine and the possible fall in the thyroid uptake of radioiodine can presumably only be explained by the increase in free thyroxine.

Influence of Dietary Cod-liver Oil and Some Fractions of Cod-liver Oil on Serum Cholesterol-level of Rats

FROM numerous experiments with humans and experimental animals it is known that the cholesterol content of the blood is greatly influenced by the amount and kind of dietary fat. In general, the relatively unsaturated vegetable fats decrease the serum cholesterol-level, while an increasing influence is observed with the relatively saturated animal fats. The highly unsaturated oils from marine animals, however, exert a potent cholesterol-lowering activity. This effect was observed in humans following the consumption of seal oil[1], sardine oil[2], whale oil[3] and pilchard oil[1,4] and also in rats fed sardine oil[5].

So far it is not yet decided what compounds of the fats are responsible for the action on cholesterol. The polyenoic acids, linoleic acid and arachidonic acid, applied in pure form, were found to be very active in lowering serum cholesterol-levels[6], whereas hydrogenation of highly unsaturated fats was accompanied by a decrease in activity[3,7]. These findings suggest that the fatty acid fraction is responsible for the effect observed. However, other experiments suggest that the unsaponifiable fraction of vegetable oils possesses cholesterol-lowering properties[8,9].

We have studied the cholesterolemic properties of cod-liver oil and some fractions thereof by feeding them to groups of 10–12 newly weaned rats in a hypercholesterolemic basal diet of the following percentage composition: casein 15, potato starch 10, wheat starch 57·5, minerals 4, vitamin mixture 2·1, choline chloride 0·2, hydrogenated coconut oil 10, cholesterol 1·0 and cholic acid 0·2. Different fats or fractions of cod-liver oil were added at the expense of equal amounts of wheat starch. Fractions of cod-liver oil were prepared after saponification with potassium hydroxide in the presence of ethanol. The soap was split by the addition of hydrochloric acid and the resulting fatty acids washed and dried in a centrifugal separator. The fatty acids were then allowed to crystallize for 24 hr. at 15° C. and filtered through a bag filter at the same temperature. The fatty acid fractions were esterified with ethyl alcohol in the presence of sulphuric acid and the resulting esters refined, washed and dried under vacuum. The unsaponifiable matter was isolated by extracting a diluted solution of cod-liver oil soap with methylated ether. After three extractions, the solvent was removed from the washed extract by evaporation, the residue re-saponified and extracted with ether. The ethereal extract was then washed with dilute potassium hydroxide solution, followed by water washes until neutral, evaporated and dried under vacuum. The aqueous soap solution from which the unsaponified matter had been extracted was freed from dissolved ether, the soap split with acid and the fatty acids purified and esterified as above to give the fatty ester fraction free of unsaponifiable matter.

After feeding the experimental diets *ad lib.* over four weeks, the amount of total serum cholesterol of each rat was determined by the Liebermann–Burchard reaction.

The results presented (Table 1) show that the growth-rate was very poor, that is, only half that obtained on a stock ration. This may be ascribed to the sub-optimal protein content and the high fat content of the diet and to the presence of cholesterol and cholic acid. With corn oil in the diet, growth-rate was highest and somewhat higher than with cod-liver oil. The esterified fatty acid fractions caused a decrease in food intake which was paralleled by a slower growth-rate.

Table 1. MEAN GAIN IN WEIGHT, FOOD CONSUMPTION AND SERUM CHOLESTEROL

Addition to basal diet	Per cent	Daily weight increase (gm.)	Daily food consumption (gm.)	Total serum cholesterol (mgm./100 ml.)
Hydrogenated coconut oil	10	1·6	6·5	784
Corn oil	10	2·3	7·2	430
Cod-liver oil	10	2·1	7·0	196
Ethyl esters of fatty acids liquid at 2° C.; iodine value 189	10	1·6	5·9	241
Ethyl esters of fatty acids liquid at 15° C.; iodine value 161	10	1·7	6·3	240
Ethyl esters of fatty acids solid at 15° C.; iodine value 135	10	1·7	6·3	277
None		2·0	8·8	884
Cod-liver oil	10	1·7	6·6	205
Unsaponified matter	0·4	2·0	8·0	750
Ethyl esters of fatty acids	10	1·2	5·9	281
Unsaponified matter + ethyl esters of fatty acids	10	1·5	6·2	321

The serum cholesterol-level obtained with corn oil was much lower than with hydrogenated coconut oil. With cod-liver oil a significantly lower value was obtained than with corn oil ($P = 0{\cdot}003$ according to Wilcoxon's test). The ethyl esters of cod-liver oil fatty acids decreased the cholesterol content to nearly the same degree as did whole cod-liver oil. The mean serum cholesterol values obtained with the cod-liver oil fractions with different melting points were not significantly different. This may be the result of incomplete separation or of equal cholesterol-lowering properties of the various fatty acids present in the different fractions. The unsaponifiable fraction, in an amount equivalent to the level present in the whole cod-liver oil, exerted no distinct hypocholesterolemic action. The combination of unsaponified fraction with the esterified fatty acid fraction resulted in a mean value not significantly different from that obtained with whole cod-liver oil ($P > 0{\cdot}05$).

From these results it is concluded that cod-liver oil has a higher cholesterol-lowering activity than corn oil. The fatty acid fraction accounts for most if not all of the activity. The unsaponifiable fraction shows no distinct activity.

Serological Relationships in the Genus *Gadus*

Little information is available concerning the serological relationships of fishes, and virtually nothing is known concerning the serology of the economically important genus *Gadus*.

Three species from this genus have been investigated in our laboratory, namely, the cod (*Gadus callarias* L.), the haddock (*G. aeglifinus* L.) and the pollack (*G. pollacius* L.). Blood was obtained from these three species by opening the animal after stunning, and taking it directly from the heart. The blood was allowed to clot, the serum separated, and merthiolate added to give a concentration of 1 : 10,000. The stock of rabbits used proved rather refractory, and the potency of the antisera was lower than might have been hoped. Three moderately satisfactory antisera were obtained, the first an anti-haddock serum *R* 71, and two anti-cod sera *R* 72 and *R* 712. Each of these antisera was produced after a course of intravenous injections of the fish serum. In the case of the anti-haddock serum, the intravenous course was followed, after a month's rest, by one series of intraperitoneal injections. In the case of the anti-cod serum, *R* 712, the second series of injections were subcutaneous. Anti-cod serum *R* 72 was produced by a single course of four intravenous injections. The amount used for each injection was 0·25 ml. of serum, and a course consisted of either three or four injections, given on alternate days. The characteristics of the antisera are shown in Table 1.

Table 1. Characteristics of the Antisera

Antiserum	Serum used from :	Reciprocal of homologous titre	Homologous photroner curve area
R 71	Haddock	1,000	107
R 72	Cod	1,000	84·5
R 712	Cod	10,000	92·8

The serological correspondence between the various species was determined using the photronreflectometer as described by Boyden and Delfaco[1]. The relationship ratios are given in Table 2. These ratios are calculated by expressing the area under the curve ($\sigma\tau$ value) of the second of the pair being compared as a percentage of the first. The reciprocal figures are also included (asterisks). Thus the cod/pollack ratios are derived from curves for antisera *R* 712 (100 : 21) and *R* 71 (27 : 100). The curves obtained from antiserum *R* 71 are shown in Fig. 1.

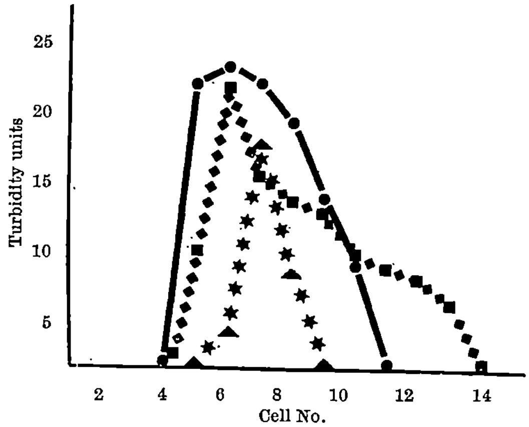

Fig. 1. ■, Haddock ; ◆, pollack ; ★, cod

Table 2. Relationship Ratios

	Antiserum used	Ratio	Mean
Cod / Haddock	*R* 712	100 : 24	25·3
	R 72	100 : 37	
	R 71	100 : 25*	
Cod / Pollack	*R* 712	100 : 21	24·0
	R 71	100 : 27*	
Haddock / Pollack	*R* 71	100 : 94	90·5
	R 712	100 : 87*	

* Reciprocal figures.

It will be seen that serologically haddock and pollack are closely related and that the cod is about equally remote antigenetically from both.

We are grateful to the Medical Research Council of Ireland for a grant to purchase the photronreflectometer used in these studies and to the Director, and Mr. R. J. Beverton, of the Lowestoft Fisheries Laboratory for sending fish sera and for enabling me to visit the Arctic in the summer of 1956 to collect the cod and haddock sera.

Cephalotoxin : the Crab-paralysing Agent of the Posterior Salivary Glands of Cephalopods

The presence of a substance, toxic to crabs, in the posterior salivary glands of cephalopods (*Giftdrusen* of the German authors) has been known for a long time[1]. When a drop of saliva collected from *Octopus* is injected into a crab, a sequence of reactions is observed followed by complete paralysis of the animal[2]. Active substances have been extracted from the posterior salivary glands of octopuses[3], and their presence has been demonstrated in external and internal secretions[4]. Most of these substances have a powerful action on crabs and upon isolated organs of molluscs and other invertebrates[5]. Tyramine, the substance first isolated from the glands by Henze[6], was, and still is, believed to be the toxic agent[7]. However, none of the extractive substances found in the posterior salivary glands of cephalopods, even tyramine, can reproduce the paralysing action of the crude extracts or of saliva. The observations of Livon and Briot[8], recently confirmed by me[9], claim a more complex composition. The active principle is inactivated by heating, does not pass through dialysing membranes and can be purified by precipitation with ammonium sulphate.

From the posterior salivary glands of *Sepia officinalis* we have now purified a protein which, when injected into crabs, has the same effect as the dialysed extract from the same organ. The active protein has been called cephalotoxin.

As a measure of purification an arbitrary unit was taken which is defined as the amount of toxin which paralyses in 15 min. a crab weighing 40–50 gm. The animal used in all the experiments was the crustacean decapod *Eriphia spinifrons*. Control animals were injected with equal amounts of extract previously heated at 100° C. for 5 min. Specific activity was calculated as units per mgm. of protein. The protein content was determined colorimetrically with the Folin-phenol reagent[10].

After several attempts the simplest and easiest procedure for extraction and purification of cephalotoxin was found to be the following.

The organs are homogenized in a Waring blendor with 2 vol. cold 0·5 per cent potassium chloride, extracted for 4 hr. in the cold with continuous stirring and centrifuged at 800*g*. The precipitate is suspended again in 1 vol. potassium chloride solution, extracted, centrifuged as before and then discarded. The combined supernatants give: units per ml. 15; protein mgm. per ml. 23·0; specific activity 0·6. The extract is brought to *p*H 4 by careful addition of 2 *M* acetic acid. The precipitate is discarded by centrifugation at 15,000*g*. The supernatant is neutralized with 1 *N* sodium hydroxide and the new precipitate is centrifuged off and discarded. (Units per ml. 15; protein mgm. per ml. 14; specific activity 1·0.) The clear supernatant is dialysed against water for 24 hr. A white precipitate is formed which is discarded by centrifugation. (Units per ml. 15; protein mgm. per ml. 8·0; specific activity 1·9.)

The final extract can be concentrated in the cold or freeze-dried. The powder, redissolved in a small amount of water, gives a positive biuret and ninhydrin reaction and an ultra-violet absorption with a maximum at 276–278 mμ. After electrophoresis on starch gel[11] at *p*H 8·5, four bands are observed migrating towards the cathode. Further purification of the extract can be achieved by adsorption on calcium phosphate gel at neutral *p*H: three components are now visible after electrophoresis. Treatment with trypsin at 37° C. and neutral *p*H produces complete loss of the activity and disappearance of the bands within 3 hr.

Cephalotoxin can be extracted from the posterior salivary glands of *Octopus vulgaris* and *O. macropus* by a procedure similar to that described for *Sepia*.

PLANT PHYSIOLOGY

Effect of Heavy Water on the Growth of *Chlorella vulgaris*

SEVERAL investigators have studied the effect of heavy water on the growth of algae[1–3]. All workers find that heavy water inhibits growth and, in concentrations approaching 100 per cent, no growth occurs. We have found recently that, while autotrophic growth of *Chlorella* is inhibited completely in 90 per cent (v/v) heavy water, growth on glucose, either in light or in darkness, is inhibited to a much smaller extent.

Chlorella vulgaris (Pearsall's strain) was grown in pure culture in medium buffered at *p*H 6·1[4]. Glucose was added, when required, in a final concentration of 1·0 per cent. The cultures were shaken at 25° C. either in darkness or in continuous light provided by fluorescent tubes giving a light intensity of 900 foot-candles. Growth was measured by a turbidometric method which was checked by hæmocytometer counts. Growth was exponential over several days and the growth constant, *k*, was calculated from $k = 24(\log_{10}n_2 - \log_{10}n_1)/t_2 - t_1$ where n_1 and n_2 are the number of cells present after t_1 and t_2 hours growth respectively.

When cultures containing glucose were shaken in light, growth was inhibited by heavy water. Not only was the rate of exponential growth reduced but also the lag period was increased (Table 1). Attempts to increase the growth-rate in 90 per cent heavy water by adaptation were unsuccessful, unlike those of Moses *et al.*[3]. In our experiments the growth-rate in 90 per cent heavy water was the same after three sub-cultures as it was originally.

Table 1. GROWTH OF *Chlorella vulgaris* IN DIFFERENT CONCENTRATIONS OF HEAVY WATER (D_2O)

Percentage D_2O (v/v)	Growth constant *k*	Approximate lag period (hr.)
0	0·70	20
50	0·46	20
70	0·35	150
90	0·20	160

The cultures contained 1·0 per cent glucose and were shaken at 25° C. in light of 900 foot-candles intensity.

In normal medium, *Chlorella* grows well in light without added glucose, and with our culture conditions, light stimulated growth even when glucose was added. However, when the medium contained 90 per cent heavy water, light inhibited growth; the cells grew fastest on glucose in darkness and illumination depressed the growth-rate. No autotrophic growth occurred at all (Table 2).

Table 2. EFFECT OF LIGHT ON THE GROWTH OF *Chlorella vulgaris* IN 90 PER CENT (v/v) HEAVY WATER (D_2O)

Glucose	−	+	+
Light	+	−	+
k—in normal medium	0·54	0·52	0·81
k—in medium with 90 per cent D_2O	0	0·23	0·17

The cultures were shaken at 25° C. The light intensity was 900 foot-candles. The concentration of glucose, when this was added, was 1·0 per cent.

The value of the growth constant, *k*, is given. Each value is the mean of two values obtained from two similar cultures.

Heavy water also had a marked effect on synthesis of chlorophyll. The illuminated cultures grown with glucose in 90 per cent heavy water were a bright orange colour. The pigments were extracted with ethanol and separated into carotenoids and chlorophylls. The absorption of the carotenoids was measured at 448 mμ and that of the chlorophylls at 660 mμ. These measurements indicated that the carotenoid content (per unit dry weight) of the orange cells was much the same as that of the normal cells but that the chlorophyll content was only one-fifth of normal.

Heavy water probably inhibits one of the dark reactions of photosynthesis[5,6]. In our experiments, the complete inhibition of autotrophic growth, which is entirely dependent on photosynthesis, compared with the partial inhibition of heterotrophic growth, indicates that the photosynthetic mechanism is more sensitive to heavy water than many other reactions. Nevertheless, reactions other than the photosynthetic ones are inhibited, and the fact that illumination reduces the growth-rate of cultures growing on glucose in 90 per cent heavy water suggests that a substance produced by the photolysis of heavy water is more inhibitory than heavy water itself.

This investigation was assisted by a grant from the Atomic Energy Authority.

Effect of Phosphorylated Methyl-naphthohydroquinones on the Response to Radiation in Barley Roots

It has been shown by Mitchell and Simon-Reuss[1-3] that some phosphorylated methyl-naphthohydroquinones are radiosensitizers of radiation-induced mitotic inhibition in chick fibroblast tissue. It seemed possible that these chemicals might be of value in the induction of mutations in plants as they afforded a means of modifying response to radiation. Accordingly, experiments were carried out to see if any of these compounds are radiosensitizers in plant tissues.

Tetra-sodium 2-methyl-1 : 4 naphthohydroquinone diphosphate (compound 1) and tetra-sodium 2 : 3 dimethyl-1 : 4 naphthohydroquinone diphosphate (compound 28), both known to be radiosensitizers in animal tissues, were used in these experiments. X-rays were provided by a 220 kV$_p$. 'Maximar' unit working at 15 m.amp., giving radiation of wavelength 0·22 A. A 1-mm. aluminium filter was used. The nominal dose-rate was 156 r./min. at a distance of 20 cm.

Seeds of barley (var. Earl) were germinated on filter paper moistened with distilled water, in Petri dishes in light at a temperature of 20 ± 2° C. Germination was apparent after 24 hr. and seeds were selected for uniformity at this stage. They were transferred to Petri dishes with filter paper moistened with 2 ml. of the chemical, and 18 hr. later irradiated as described above.

With doses less than 300 r., mitosis is at a minimum 3 hr. after irradiation, and root tips were fixed in glacial acetic acid at this time for studying mitotic inhibition. This was done by hydrolysing root tips in N hydrochloric acid at 60° C. for 12 min. and staining with Feulgen's reagent. Root tips were squashed and counts made of the number of cells in the different stages of mitosis. The seedlings were grown in the Petri dishes for up to five days after irradiation, and each day 50 seedlings were analysed for weight and length of root and shoot.

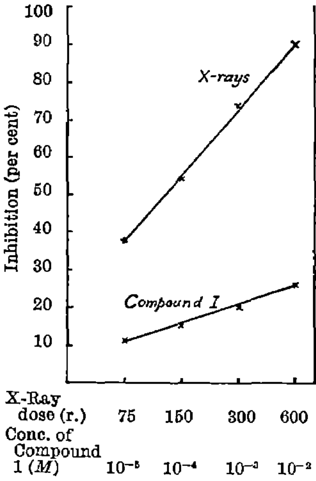

Fig. 1. Mitotic inhibition 3 hr. after irradiation

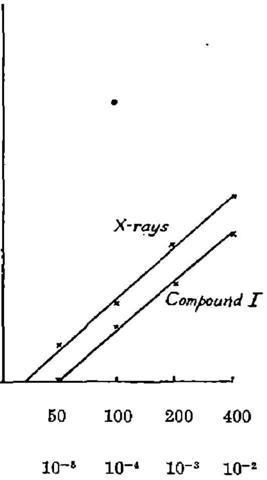

Fig. 2. Inhibition of increase of root fresh-weight 5 days after irradiation

Mitchell and Simon-Reuss[1] pointed out that to test for potentiation rigorously it is necessary to compare the effect of half-amounts of the two agents with the mean effect of the agents acting independently, and that there must also be a linear or sigmoid relation up to 50 per cent effect between response and dose for the separate agents. The effect measured with each of the agents acting alone should not be greater than 50 per cent. Figs. 1 and 2 show that there is a linear response to X-rays and compound 1 with mitotic inhibition 3 hr. after irradiation and with inhibition of weight of root five days after irradiation. Throughout these experiments the increases in weight and length of roots and shoots showed parallel responses to the treatments, so that only results for weights of roots are quoted.

Table 1 shows that compound 1 and X-rays have an additive effect on root growth five days after irradiation. Since growth is the product of many factors, it is not surprising that no potentiation can be demonstrated when measuring such a complex function. Five days after irradiation was chosen as the time to look for potentiation, as it is the earliest time at which the individual dose responses are linear. In fact, on the day after irradiation there is a stimulation of growth over the controls in all treatments, this effect gradually vanishing until on the fifth day the linear inhibition appears. Irrespective of the time after irradiation that root measurements were taken, no potentiation was observed. Compound 28 was not used for the experiments on growth measurements because of these difficulties of interpreting the results.

The examination of mitotic inhibition revealed the effects of the two chemicals and X-rays a short time after treatment, when responses should still be apparent and not masked as in the study of the increase of root weight and length several days after treatment. No measurements were made of chromosome abnormalities, but Bora[4] showed in broad bean roots that although these two chemicals do not cause chromosome breaks they increase the frequency of breaks induced by X-rays.

It is clear from Table 1 that compounds 1 and 28 have a radiosensitizing action on the mitotic inhibition induced by X-rays in barley roots. Both chemicals are themselves mitotic inhibitors, compound 28 being the more powerful. Compound 28 causes

Table 1

Treatment	Mitotic inhibition (per cent)	Potentiation factor	Treatment	Inhibition of fresh weight of root (per cent)	Potentiation factor
100 r. X-radiation	49·6		400 r.	49·1	
10^{-2} *M* Compound 1	26·7		10^{-2} *M* Compound 1	40·5	
5×10^{-3} *M* Compound 1	59·9	1·57 ± 0·16*	5×10^{-3} *M* Compound 1, followed after 18 hr. by 200 r.	46·1	1·03 ± 0·11
10^{-3} *M* Compound 28	38·8				
5×10^{-4} *M* Compound 28, followed after 18 hr. by 50 r. X-radiation	71·2	1·61 ± 0·18*			

* Significantly greater than 1 at 0·1 per cent level of probability. These figures are the means of five separate experiments.

metaphase accumulation, a finding which agrees with that of Mitchell and Simon-Reuss[2].

It appears from the above results that these two phosphorylated methyl-naphthohydroquinones act as radiosensitizers for mitotic inhibition in barley roots, and that this action is similar to that reported for chick fibroblasts in tissue culture and other animal tissues. Because they afford a means of modifying radiation response, they will be used to study the effect on X-ray induction of mutations in plants.

This work was carried out under a Nuffield Foundation grant and in collaboration with Prof. J. S. Mitchell, of the Department of Radiotherapeutics, University of Cambridge.

Synthesis of Long-Chain Fatty Acids from 2-^{14}C-Acetate and ^{14}C-Glucose in *Trichoderma viride*

Although the synthesis of saturated fatty acids by the formal condensation of acetate units is well established, less attention has been paid to the formation of the common unsaturated acids (oleic, linoleic and linolenic) and their relationship to the saturated acids. The similarity in structure of oleic, linoleic and linolenic acids suggests a linked synthesis, and two processes have been considered: first a desaturation process leading from oleic via linoleic to linolenic acid, and secondly a hydrogenation process operating in the opposite direction. *Trichoderma viride*, a fungus which readily synthesizes palmitic, stearic, oleic, linoleic and linolenic acids, was chosen for studies with substrates labelled with carbon-14 in an attempt to obtain further information on the synthesis of unsaturated acids.

Mycelium was grown at 25° C. in a shaken 2 per cent glucose/acetate medium (*p*H 6·8), containing per litre: ammonium nitrate, 5·0 gm.; dihydrogen potassium phosphate, 3·5 gm.; crystalline magnesium sulphate, 2·5 gm.; ferric chloride, 0·08 gm.; zinc sulphate, 0·025 gm.; D(+)-glucose, 20·0 gm. and 5 ml. acetic acid neutralized with sodium hydroxide. After either two or four days growth the fungus was transferred to a single flask and equilibrated (4 hr.) with non-radioactive medium of similar salt composition containing, for the acetate experiments, 10 gm. D(+)-glucose and 0·25 gm. sodium acetate per litre, and for the glucose experiment 5 gm. D(+)-glucose and 0·125 gm. sodium acetate. At the end of this time 2-^{14}C-acetate or generally labelled ^{14}C-glucose was added, and after a suitable time the mycelium was removed by filtration and killed in boiling ethanol. Lipids were extracted in the usual way and the fatty acids obtained were separated by reversed-phase column chromatography[1], plated out and counted. Oleic and palmitic acids are not separable by this method, and the figure for palmitic acid was obtained from a second separation following removal of oleic acid after its conversion into short-chain acids by oxidation with alkaline permanganate. The figure for oleic acid was calculated by difference from that for the mixed oleic and palmitic acids.

The results in Table 1 show that radioactivity is incorporated into all the long-chain fatty acids within 3 hr. Closely similar results were obtained with 1- or 5-hr. periods. In every case the two saturated acids present (palmitic and stearic) and one of the unsaturated acids (oleic) had relatively high specific activities, whereas the other unsaturated acids (linoleic and linolenic) had much lower specific activities. This result obtained both in 2-day-old mycelium, which is rapidly synthesizing fatty acids, and in 4-day-old mycelium, in which fat synthesis is slow. Analysis of the free fatty acids (2·2 per cent of the total fatty acids), phosphatide fatty acids (41·4 per cent) and glyceride fatty acids (56·3 per cent) also showed the same distribution of radioactivity.

Table 1. Incorporation of Radioactivity into Long-Chain Fatty Acids after 3 hr. Growth on 2-^{14}C-Acetate or Generally Labelled ^{14}C-Glucose

Fatty acid	Age of mycelium and radioactive substrate					
	2-day glucose		2-day acetate		4-day acetate	
	c.p.m./mgm.	gm./100 gm. fatty acid	c.p.m./mgm.	gm./100 gm. fatty acid	c.p.m./mgm.	gm./100 gm. fatty acid
Palmitic	508	20·9	9,628	20·9	1,129	21·3
Stearic	367	5·4	2,570	5·4	940	5·6
Oleic	329	29·0	7,509	29·0	701	24·0
Linoleic	53	42·3	1,522	42·3	149	44·0
Linolenic	65	2·2	434	2·2	48	5·0
Total c.p.m. supplied	$54 \cdot 3 \times 10^6$		$17 \cdot 4 \times 10^6$		$14 \cdot 5 \times 10^6$	

These results indicate clearly that oleic acid is the first of the unsaturated acids to be formed and give little support to the hydrogenation hypothesis in which it is assumed that the most unsaturated acid is formed first. In view of the fact that similar results were obtained using either radioactive glucose or radioactive acetate as a carbon source it also seems unlikely that triose units are involved, as has been suggested, in the synthesis of unsaturated acids. A more probable explanation of the results would be that glucose is broken down into C_2 units before its incorporation into fatty acids.

In a further experiment 2-day-old mycelium, after being fed for 3 hr. with 2-^{14}C-acetate (see Table 1), was transferred, after careful washing, to a similar but non-radioactive medium for a further 2 days. During this time mycelium dry weight and lipid weight approximately doubled. At 4 days the material was harvested, and the following specific activities (c.p.m./mgm.) were obtained: palmitic acid, 9,612; stearic acid, 2,924; oleic acid, 6,406; linoleic acid, 5,939; and linolenic acid, 2,309. None of the fatty acids showed any significant decrease in specific activity, and this is accounted for by the fact that there was a rise in the total count in the fatty acids from $44 \cdot 9 \times 10^4$ c.p.m. at 2 days to $72 \cdot 2 \times 10^4$ at 4 days. This could be the result of insufficient washing at the 2-day stage or it may be caused by the formation of a 'pool' of radioactive precursor within the tissue[2]. It is interesting, however, that whereas the specific activities of palmitic, stearic and oleic acids show only a small change, those of linoleic and linolenic acids have increased severalfold. This again indicates that these acids are formed later than oleic acid, and is consistent with synthesis by successive dehydrogenation of oleic acid, although other explanations cannot be dismissed on the present evidence. These results will be reported and discussed in detail elsewhere.

We are most grateful to Dr. D. W. Turner (Department of Chemistry, Imperial College, S.W.7) for access to a proportional counter and for guidance in its use.

Effects of Gibberellic Acid on Winter Pasture Production

The problem of restricted winter growth of pastures is of agronomic importance in many countries. This is especially true over large areas of Australia where fodder conservation, as one solution, is not economic. The possibility, inherent in the work of Morgan and Mees[1,2], Leben and Barton[3], Wittwer *et al.*[4,5] and Corns[6], that gibberellic acid might increase winter growth of continuously grazed pastures, does not appear to have been exploited beyond an initial experiment of Scurfield and Bull[7]. Results of that experiment were sufficiently encouraging to warrant our pursuing the matter further.

Experiments were carried out during the winter of 1958 on grazed pasture of *Phalaris tuberosa* and *Trifolium subterraneum,* sown twelve years previously. Four sites were chosen at random and, within each of these, four sub-sites. On each sub-site, sixteen plots (each of four sq. lk.) were located at random (subject only to the restriction that each had complete foliage cover). In each group of sixteen plots, four at random received nitrogen (as ammonium sulphate =224 lb./acre), four an aqueous solution of gibberellic acid (=3·69 oz./acre), four gibberellic acid plus nitrogen, and four were untreated (controls). Prior to treatment, all plots were clipped to ground-level. After treatment, they were clipped to this level on four occasions: the harvest data (lb. dry matter per acre) are given in Table 1.

Compared with controls, plots treated with gibberellic acid produced a greater yield of both grass and clover at harvests I and II, an equivalent yield of grass and a lesser yield of clover at harvest III, and a lesser yield of both at harvest IV. Over the four harvests so far taken, there was a significant increase in total yield of dry matter. This result confirmed that obtained previously[7], but not that of Morgan and Mees[1,2]. They found, after applying gibberellic acid (=2 oz./acre) to pastures at various times from spring to autumn "in no case any net increase of yield over two or more cuts". More interesting, however, than an overall increase in yield was the stimulation of growth at a time of normally slow growth. Continuous meteorological records kept for the site showed that this alteration could be achieved under conditions of adequate rainfall and minimum temperatures as low as −9·5° C. (grass) and −4·5° C. (screen) (compare the records of Leben and Barton[3] and Wittwer and Bukovac[4]).

Changes in the botanical composition of the harvested material were of interest. Treatment with gibberellic acid caused a significant ($P < 0 \cdot 05$) depression of percentage clover in the material harvested on the second and third occasions. How far this was a direct effect of gibberellic acid and how far it reflected an altered competitive status of the species present was uncertain. The result failed to confirm that of Morgan and Mees[2], who found treatment with gibberellic acid to cause no change in the botanical composition of swards over a period between treatment and a third cut.

There were significant ($P < 0 \cdot 001$) reductions in percentage total nitrogen of *P. tuberosa* (from 4·25 to 3·66 at harvest I, 5·37 to 4·13 at harvest II and 4·57 to 4·20 at harvest III) as a result of gibberellic acid treatment. This confirmed earlier results[1–3,7] (not, however, those of Wittwer *et al.*[5]) obtained with other grasses. Despite such reductions, the total yield of nitrogen (Table 1) over all four cuts was significantly greater from plots treated with gib-

berellic acid than from control plots. Analyses have so far failed to demonstrate any similar effect of gibberellic acid on the nitrogen content of the clover.

The leaf 'burning' caused by the added ammonium sulphate makes the interpretation of the yield results from such plots somewhat uncertain, but evidently the quantitative effects of added nitrogen upon yield did not resemble those of gibberellic acid. Regarding the effects of nitrogen and gibberellic acid added together, no evidence of interaction between the two in relation to total yield was obtained. It was noted that both *Phalaris tuberosa* and *Trifolium subterraneum*, irrespective of simultaneous nitrogen application, showed chlorosis and other symptoms of gibberellic acid treatment[8,9], though by harvest IV chlorotic symptoms at least had disappeared.

An initial grazing experiment using Merino wethers on a similar pasture to the above has so far: (*a*) confirmed that treatment with gibberellic acid (=1·6 oz./acre) could increase late-winter pasture growth and (*b*) provided no evidence of a deleterious effect of herbage so treated on either the health or live weight of sheep after two months grazing. This latter fact supports the finding of Peck *et al.*[10] that gibberellic acid, administered in various ways directly to small animals, was non-toxic.

The results of the above experiments will be considered more fully elsewhere.

We are grateful to Mr. G. A. McIntyre for the statistical analysis of the data in Table 1.

Geotropic and Morphological Alterations in Rice Seedlings caused by Plant Growth Regulators

During some investigations into the effects of gamma-BHC on rice seeds a number of experiments were carried out to test whether BHC was behaving in a similar way to plant growth substances in producing abnormalities. These experiments were carried out because it was found that gamma-BHC inhibited root growth at low concentrations (for example, in aqueous solutions at 10^{-5} *M*, root growth was reduced to half that of the controls) and because of a recent suggestion by MacLagan[1] that some of the chlorinated hydrocarbons, including BHC, might behave in a similar way to auxins in plant tissue. It has now been found (unpublished work) that BHC does not behave as an auxin so far as rice seedlings are concerned. Nevertheless, during these experiments some results were obtained which may shed some light on current theories of geotropism and also on the effects that auxins have on morphogenesis.

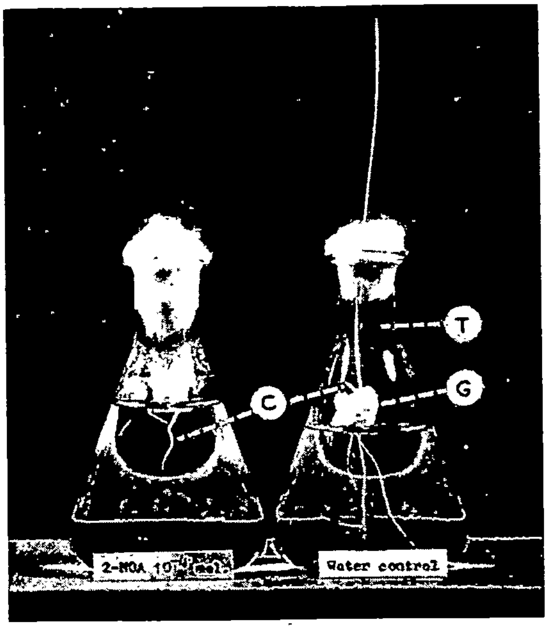

Fig. 1. Rice seedlings 7 days old growing in 10^{-4} *M* 2-naphthoxyacetic acid (left) compared with control (right). *C*, coleoptile. The apparatus consists of a 100-ml. conical flask containing 100 ml. of the test solution; the seed is held at the surface of the solution in a 10-mm. bore glass tube (*T*) the end of which is covered by cotton gauze (*G*); a cotton-wool plug holds the tube in position

Rice seedlings were germinated and grown for seven days in the apparatus shown in Fig. 1. The seeds were held at the surface of aqueous solutions of substances which have auxin activity and 'anti-auxins'; distilled water was used as control. Ten replicates were used for each treatment. Linear growth measurements and photographic records were made at the end of the experimental period. The substances with auxin activity were β-indolylacetic acid, naphthalene-1-acetic acid, methyl*iso*butylcarbonyl ester of 2,4,5-trichlorophenoxyacetic acid (2,4,5-T MIBC ester) (a crude preparation containing 71 per cent w/w) and 2-naphthoxyacetic acid. The substances used which are usually classed as anti-auxins were 1-naphthoxyacetic acid, 2,3,5-tri-iodobenzoic acid and α-(1-naphthylmethylsulphide)-propionic acid.

All the substances with auxin activity showed very similar effects on the seedlings though the concentrations necessary for the various effects differed. The three most obvious effects were inhibition of root growth, the production of an epicotyl (not present in the controls) and the reversal of shoot geotropism. The lowest concentrations required to produce an epicotyl and reverse shoot geotropism were as follows: 10^{-3} *M* indolylacetic acid, 10^{-4} *M* 2-naphthoxyacetic acid, 10^{-5} *M* naphthalene-1-acetic acid and 10^{-6} *M* 2,4,5-T MIBC ester. At these concentrations at least 60 per cent of the coleoptiles showed complete reversal of geotropism on all three occasions when these substances were tested. The epicotyls produced at these concentrations were 2–4 mm. long. In a large number of germination tests carried out in this laboratory on moistened filter paper or sand

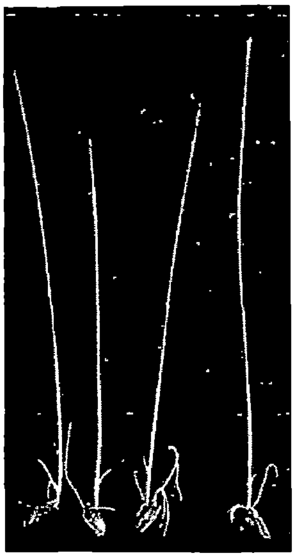

Fig. 2. Photograph of 7-day old rice seedlings showing the reversal of root geotropism caused by 10^{-4} *M* 1-naphthoxyacetic acid. Note that secondary roots have the normal positive geotropic response

trays both in the light and in the dark there has never been any evidence of the production of an epicotyl. However, additional experiments have now been carried out in which rice seeds were placed in beakers and submerged beneath various depths of water from 3 to 10 cm.; under these germination conditions in the dark, epicotyls 4–6 mm. long were produced, but under the same conditions in diffuse daylight no epicotyls were found. Continuous aeration of the water in the case of submerged-germination tests in the dark decreased the size of the epicotyls to 2–4 mm. It would seem, therefore, that an epicotyl is normally produced under dark, poorly aerated conditions, but that high concentrations of substances with auxin activity are capable of inducing its formation even under light, well-aerated conditions. Microscopic examination of transverse sections showed that there were no distinguishable anatomical differences between epicotyls produced by the dark, poorly aerated conditions or by application of substances with auxin activity. This similarity would be expected if epicotyl formation is due to a rise in auxin concentration. Yamada[2] has shown that rice coleoptiles grow to a greater length under water than in the air, and has presented evidence which suggests that this is due to the reduced capacity of the tissues to destroy auxin when submerged; submersion, he found, was equivalent to a 20–30-fold increase in indolylacetic acid. The absence of an epicotyl in the light, even in submerged seedlings, would fit in with the demonstrated presence in plant tissues of the light-stimulated indolylacetic acid oxidizing system, originally shown by Galston[3] in etiolated pea epicotyls.

One of the most general effects of the substances with reputed anti-auxin activity was inhibition of root growth at and above the following concentrations: 10^{-5} *M* 1-naphthoxyacetic acid, 10^{-8} *M* 2,3,5-tri-iodobenzoic acid, and 10^{-8} *M* α-(1-naphthylmethylsulphide)-propionic acid. In this way they showed a similarity with the auxins, but unlike the experiments with auxins, there was never any evidence of an epicotyl being induced to form. Neither α-(1-naphthylmethylsulphide)-propionic acid nor 1-naphthoxyacetic acid reversed coleoptile geotropism, though 2,3,5-tri-iodobenzoic acid did cause a positive response in approximately 20 per cent of the seedlings at 10^{-6} and 10^{-7} *M*. The most interesting result was obtained with 10^{-4} *M* 1-naphthoxyacetic acid: when seeds were grown at the surface of a solution of this strength, 60 per cent or more of the seedlings showed a reversal of root geotropism, and the roots grew upwards into the air away from the solution (Fig. 2). In the cases where root geotropism was reversed, the roots were strongly inhibited and showed only 20–30 per cent growth compared with the controls. This reversal of root geotropism was obtained on all three occasions when this concentration of 1-naphthoxyacetic acid was tried.

These results are considered to support the classical theory of geotropism in which it is postulated that the shoot contains sub-optimal concentrations of auxin, whereas the roots contain optimal or supra-optimal concentrations. It follows that if the effective concentration of auxin in the shoot is raised to a supra-optimal level it should behave geotropically as a root; conversely, if the effective concentration of natural auxin in the root is reduced—for example, by an anti-auxin—to a sub-optimal level, then the root should behave as a shoot. It is interesting to note that out of the five 'anti-auxins' which Street[4] tested, 1-naphthoxyacetic acid was the most effective in counteracting the effect of a natural auxin which accumulates in excised tomato roots and causes 'ageing'. It may be significant, therefore, that 1-naphthoxyacetic acid was the only substance used in the present investigations which reversed the geotropism in rice roots.

These results will be discussed more fully in a later publication.

Grateful acknowledgment is made to Mr. S. J. Wakka for technical assistance and to the Director of Agriculture, Sierra Leone, for allowing publication of this work.

Prolonging Dormancy in *Vitis vinifera* with Gibberellin

At Davis, California, grape buds developing on the basal portions of shoots normally enter a dormant stage about September. By the following April the buds usually begin rapid growth. Both a small amount of cold and a certain interval of time are required for dormancy to break. If the dormant buds could be made to grow in the autumn, the crop of the following year could be estimated. Since gibberellin has been reported to break the dormancy of buds in peach[1] and potato[2,3], and of epicotyls in the tree peony[4], it was tested for this purpose on grapes.

The potassium salt of gibberellic acid, supplied by Merck and Co., contained about 80 per cent active ingredient.

In one experiment, Zinfandel vines were sprayed with gibberellin at 0, 10, 50 or 250 p.p.m. on September 6, 1957, two vines per treatment. At this time the foliage was still green and the percentage of total

Table 1. GROWTH OF SHOOTS ON APRIL 19, 1958, ON ZINFANDEL VINES SPRAYED THE PREVIOUS AUTUMN WITH GIBBERELLIN

Concentration of gibberellin (p.p.m.)	Average length per shoot (in.)	No. of shoots per vine on spurs	No. of water sprouts* per vine
0	3·0	18	56
10	1·7	14	34
50	1·7	3	8
250	1·6	1	2

* Water sprouts refer to shoots arising from wood more than one year old.

soluble solids of fruit was about 20. After the leaves had fallen, in November, buds in all treatments were still dormant. In January 1958 vines were pruned to 9–11 spurs, each bearing 2–3 buds[5]. On April 19, control shoots were about 3 in. long (Table 1). The number of shoots decreased with increasing concentration of gibberellin, indicating that dormancy had been prolonged by gibberellin. Results were comparable in an experiment with the Tokay variety.

In a second type of experiment, cuttings of Tokay canes about 16 in. long were taken from the vineyard on December 4, 1957, and placed in a greenhouse with their bases in solutions containing 0, 0·01, 0·1, 1, 10 or 100 p.p.m. of gibberellin. The solutions, about 3 in. deep, were changed each week. There were thirty cuttings per treatment. At later intervals the cuttings were examined to see whether buds had begun growth. A cutting was said to have initiated growth when green was visible on one or more buds of a cutting. The results (Table 2) show that the higher the concentration of gibberellin, the longer the development was delayed. With one exception, no buds began growth by February 20 on cuttings placed in gibberellin in the range 1–100 p.p.m. This experiment was repeated with other sets of cuttings after they had been stored at a temperature of about 32° F. for two, four or six weeks. The trends were similar.

Table 2. NUMBER OF TOKAY CUTTINGS OUT OF THIRTY THAT SHOWED BUD GROWTH ON VARIOUS DATES AFTER BEING PLACED IN SOLUTIONS OF GIBBERELLIN ON DECEMBER 4, 1957

Concentration of gibberellin (p.p.m.)	Date of readings		
	Jan. 23, 1958	Feb. 6, 1958	Feb. 20, 1958
0	7	9	17
0·01	3	8	17
0·1	1	5	13
1	0	0	0
10	0	0	0
100	0	0	1

It is of interest that gibberellin prolongs dormancy of buds of *Vitis vinifera* despite the fact that growth of shoots is greatly stimulated[6]. Gibberellin may be of use for retarding bud break in the spring in regions of early frosts.

This work was supported financially by a grant from Merck and Co., Rahway, New Jersey.

BIOLOGY

Acquired Immunological Tolerance of Heterografts

ACQUIRED immunological tolerance of heterologous cells is of much lower degree than tolerance of homologous cells[1]. In experimental embryonal parabiosis[2], a large quantity of powerful antigenic stimulus is administered; this acts for a relatively long time during the 'adaptive period' and usually results in the formation of cell chimeras. A relatively high degree of heterologous tolerance was sometimes obtained by this method, for a prolonged survival of heterografts has been found in turkey–chicken parabionts[1], and an interspecific blood chimera demonstrated[3].

The degree of tolerance to heterografts has now been studied in further turkey–chicken parabionts. In one turkey parabiont, a chicken skin graft survived for three months and grew feathers. No chicken erythrocytes were demonstrated during this period in the turkey's blood. It is possible that no erythrocyte chimera was formed in this parabiont, or that, if it was formed, it disappeared from causes other than the immune reaction.

Skin heterografts from two chickens were applied to one turkey parabiont with persistent erythrocyte chimerism at the age of one year. Neither of the donors was the partner in the embryonal parabiosis. The grafts survived for 80 days, when the recipient died. A skin homograft from a turkey had been applied at the same time. This also survived for the whole 80 days. In control turkeys, skin homografts survive for only 10–14 days. Gamma-globulins were demonstrated by paper electrophoresis in the serum of this parabiont; it was therefore not a case of agammaglobulinæmia. Moreover, a guinea-fowl heterograft was destroyed by the turkey in the normal time. Immunological reactivity against heterografts from other species was thus maintained.

This example of a high degree of heterologous tolerance shows that in tolerance between turkeys and chickens, the immune reaction against individual antigenic differences within the donor species is lost, as well as its response to the individual antigens of the recipient's own species.

We then studied the occurrence of interspecific blood chimerism in turkey–chicken parabionts. Agglutination by specific antiserum revealed the presence of turkey erythrocytes five weeks after hatching in six chicken parabionts out of eight, and in four seven weeks after hatching. In one chicken, turkey erythrocytes were present up to the tenth week after hatching. Taking into account the length of the life of avian erythrocytes[4], most of these cases cannot represent a mere survival of the partner's erythrocytes exchanged during embryonal parabiosis, but must involve a repopulation by the partner's transplanted hæmatopoietic cells. They are therefore interspecific erythrocyte chimeras.

In one turkey, chicken erythrocytes were demonstrated up to the time of the bird's death at the age of 14 months, and actually comprised the majority of its erythrocytes. Chicken erythrocytes were also demonstrated in a specimen of blood taken after death.

The question arises whether this may not have been a case of pseudochimerism, as observed in avian bird embryos after transplantation of adult spleen cells[5]. Transplantation of prospectively immunologically active cells from the chicken parabiont to the turkey partner might have occurred during embryonal

Table 1

Plasma taken :	Chicken plasma No.:	Erythrocytes of chicken No.: 728	734	882	883	885	886	2911	Titre of anti-turkey hæmagglutinins

	2300	–/–	–/–	–/–	–/–	–/–	–/–	–/–	64

Chick No. 2120 immunized with blood of chimeric turkey parabiont (age one year). Chick No. 2300 immunized with blood of control turkey. Citrated plasma used for agglutination reactions undiluted, if not stated otherwise. Isoagglutination read after 30 min./24 hr.; titre of anti-turkey hæmagglutinins determined after 30 min.

* Plasma diluted 1 : 10.

parabiosis. These cells could probably acquire tolerance to the host's antigens. Later in life, however, they might lose this tolerance and form antibodies against turkey agglutinogens, which would then combine with the host's erythrocytes. Agglutination of these sensitized turkey erythrocytes by antiserum against chicken blood would thus simulate the presence of chicken erythrocytes—a case of pseudochimerism. In order to exclude this possibility, chicken agglutinogens were demonstrated in the blood of this chimera by means of immunization. Chickens do not possess natural agglutinins and do not form them even when immunized with turkey blood. Immunization of chickens with the blood of the chimera, however, resulted in the formation of *iso*agglutinins which also agglutinated the erythrocytes of other chickens in a relatively high titre (Table 1). Individual chicken antigens must have been present in the blood of the chimera to induce the formation of these antibodies. The demonstration of chicken antigens thus showed that this was actually a case of prolonged interspecific chimerism.

Table 2

Serum	Titre of serum: Non-absorbed	Absorbed: With normal erythrocytes of turkey No. 41	With normal erythrocytes of chicken No. 735	With erythrocytes released after agglutination with chicken isoimmune serum of turkey No. 10/11 (chimera)	With erythrocytes released after agglutination with chicken isoimmune serum of chicken No. 725
Against turkey erythrocytes	16	< 4		16	
Against chicken erythrocytes	16		< 4		< 4

Plasma diluted 1 : 2 and absorbed with equal volume of 33 per cent erythrocyte suspension (final dilution 1 : 4).

Another question investigated was whether erythrocytes with *both* chicken and turkey antigens occurred in the turkey chimera, in addition to chicken and turkey erythrocytes. Erythrocytes of the chimera were exposed to antisera against chicken erythrocytes. Clumped erythrocytes were separated from free cells by differential centrifugation, thus separating erythrocytes with chicken agglutinogens from those without them. The clumps were then broken up mechanically. Although the cells were free in physiological saline, they agglutinated in any serum, including their own. It was thus an example of the agglutination of sensitized erythrocytes in a protein medium. An attempt was therefore made to demonstrate turkey agglutinogens in these cells by absorption of chicken serum against turkey blood. This, however, did not reduce the agglutinin titre (Table 2). Erythrocytes containing turkey and chicken agglutinogens simultaneously were thus not demonstrated in the blood of this chimera by the method used in the present experiment.

Antibody Formation in Tissue Culture

While the production of antibodies by explanted tissues or cells from immunized animals is readily demonstrable, most attempts to initiate antibody formation *in vitro* have met with failure. Only recently has the original claim for success[1] been substantiated by the observations of Stevens and McKenna[2], who found that normal rabbit spleen produced antibody to bovine γ-globulin after exposure to this antigen *in vitro*, but only if either the rabbit or the spleen had previously been treated with *S. typhi* endotoxin.

This report describes the *in vitro* initiation and production of two different antibodies in cultivated lymph node cells of normal rats: one reactive with the bacteriophage *T*2, the other with hæmocyanin (busycon canaliculum). In order to induce the formation of the *T*2 antibody, it was necessary first to expose the virus to the cells of a rat peritoneal exudate obtained 48 hr. after intraperitoneal injection of beef infusion broth[3]. These cells (90 per cent macrophages) were washed once with buffered saline and then were packed by centrifugation. The packed cells (approximately 1·4 × 10^8) were suspended in 5 ml. buffered saline containing 10^3 *T*2 phage. The mixture was incubated at 37° C. for 30 min. The cells were then sedimented by centrifugation at 1,000 r.p.m., washed twice with buffered saline, ground in a Ten Broeck homogenizer and passed through a Seitz filter.

2 ml. of this cell-free filtrate were distributed among eight Esmarch dishes which contained rat lymph node cells maintained in Trowell's synthetic medium[4]. Preparations of untreated bacteriophage in comparable dilution, and of suspensions of normal rat macrophages alone, were added to other lymph node cultures. The plates were incubated at 37° C. under a 4 per cent carbon dioxide atmosphere. The supernatant fluids from these cultures were removed after varying periods of time and to one volume of fluid was added one volume of saturated ammonium

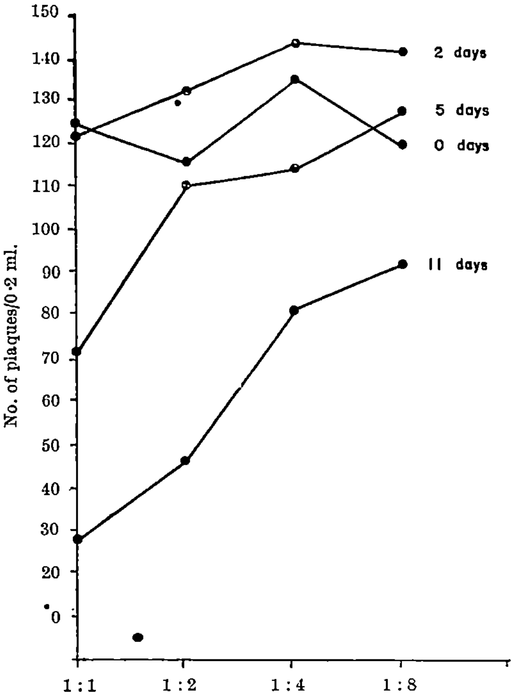

Fig. 1. Effect of length of incubation on the formation of *T2* bacteriophage neutralizing antibody from rat lymph node cell tissue cultures exposed to rat macrophage-treated *T2* bacteriophage

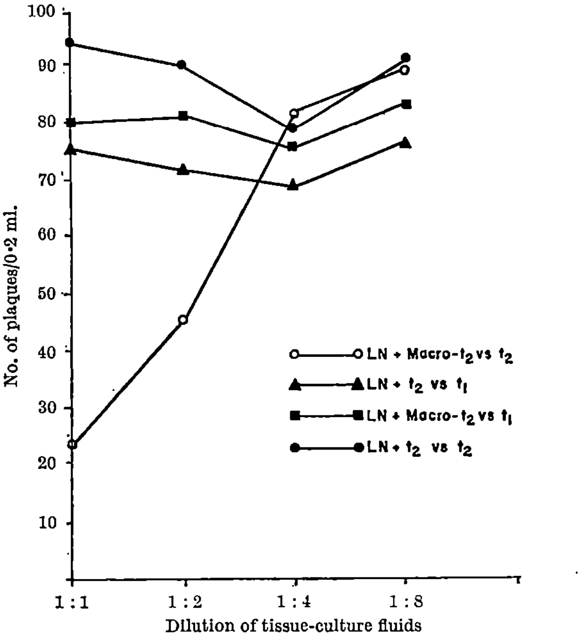

Fig. 2. Neutralization of *T1* or *T2* bacteriophage by fluids from rat lymph node cell tissue cultures exposed to either *T2* bacteriophage or rat macrophage-treated *T2* bacteriophage

sulphate. The resulting precipitate was dissolved in one-eighth the original volume and dialysed overnight against buffered saline of *p*H 7·6. These concentrated fluids were tested for phage neutralization by adding dilutions of the fluid to constant numbers of *T2* phage, incubating for 30 min. at 37° C., plating on *E. coli B*, and counting plaques after 24 hr.

Phage neutralization was found only with fluids from lymph-node cells that had been exposed to macrophage-treated phage particles. As may be seen in Fig. 1, the neutralizing substance appeared on the fifth day and increased in titre to the eleventh day, after which the cells began to lose viability. Fluids which neutralized *T2* did not neutralize *T1* as shown in Fig. 2. The pretreatment of the virus by rat macrophages could not be replaced by treatment with rabbit macrophages or with HeLa cells. It was also found that the treatment of the phage with rat macrophages which had been damaged by freezing and thawing or by exposure to the Mickle vibrator was ineffective. However, a homogenate from rat macrophages prepared by the use of a Ten Broeck grinder could be substituted successfully for intact macrophages.

A primary antibody response to hæmocyanin was induced in lymph-node cells from normal rats by the addition to the culture of a cell-free filtrate from a mixture of hæmocyanin and rat macrophages (0·25 mgm. nitrogen/ml. hæmocyanin and approximately $1 \cdot 4 \times 10^8$ cells were used). Hæmocyanin alone again failed to elicit antibody formation. The titres of concentrates of tissue culture fluids, prepared in the same manner as above, are shown in Table 1. The hæmagglutination method of Boyden[5] was employed. If the tissue-culture fluids were freed of protein with perchloric acid, hæmagglutination activity was lost.

Table 1. HÆMAGGLUTINATION TITRES OF TISSUE CULTURE FLUIDS AGAINST HÆMOCYANIN

Post-incubation time (days)	Hæmagglutination titres Antigen added to rat lymph node tissue cultures	
	Hæmocyanin	Macrophage-treated hæmocyanin
0	0†	0
4	0	0
7	0	1 : 10
11	0	1 : 80–1 : 160

† Titre less than 1 : 10.

Further work is under way to characterize the *T2* phage-neutralizing substance.

Glutamine Metabolism of Normal and Malignant Cells cultivated in Synthetic Media

PREVIOUS communications from this Laboratory[1,2] have reported changes in the amino-acid content of synthetic medium *M* 150 during cultivation of a variety of freshly explanted tissues and have established a characteristic pattern of change with each tissue studied[3]. Cultivation of strain *L* (Earle) cells of mouse fibroblastic origin revealed a pattern of changes in the synthetic medium differing significantly from that of the freshly explanted tissues in regard to the metabolism of glutamine[4]. These studies have now been extended to a number of cell lines of malig-

Table 1. CHANGES IN GLUTAMINE CONCENTRATION OF SYNTHETIC MEDIUM DURING CULTIVATION OF VARIOUS CELLS AND TISSUES

Tissue cultures	Change in glutamine content of medium*

J-96 (human leukæmic)	– – –
J-111 (human leukæmic)	– – –
J-128 (human leukæmic)	– – –

* +, Increase –, decrease. Changes are based on most active period of metabolism of each culture type.

nant origin and appear to have established a consistent difference between the two types of cultures. All cultures of freshly explanted tissues so far examined accumulate glutamine in the culture medium, while all established cell lines studied utilize this amide from the surrounding fluid.

The composition of the synthetic medium and the methods of tissue cultivation have been described previously[1–5]. Samples of the culture medium were removed at appropriate intervals, pooled, and aliquots analysed by paper chromatography[1,2], using both one-dimensional and two-dimensional methods for separating completely the amino-acids of the culture medium. The results of these experiments are summarized in Table 1.

It is evident that the freshly explanted tissues show a marked increase in the glutamine content of the medium. On the other hand, the established cell strains, which are largely of human malignant origin, bring about a marked decrease in the glutamine concentration. This decrease is greatest with the HeLa cell strain and the three lines of human leukæmic cells, while the human kidney, human amnion, and strain *L* cells show the same change to a lesser degree. The behaviour of monkey kidney cells appears to depend on the method of preparation of the cultures. Primary cultures prepared from freshly explanted fragments cause a slight increase in glutamine content of the medium, while primary cultures prepared by trypsinizing the tissue to a cell suspension bring about a slight decrease in glutamine concentration. Similar variation in glutamine metabolism by monkey kidney cells cultivated in media supplemented with serum has been observed by Eagle *et al.*[6].

The completely synthetic medium used in these experiments supports the survival of freshly explanted tissues for more than 30 days and maintains the established cell strains for somewhat shorter periods. The results presented in Table 1 were obtained, therefore, under conditions of survival and active metabolism, but not of rapid propagation. It should also be noted that synthetic medium *M* 150 contains a high level of glutamic acid in addition to glutamine, but that the changes in glutamine content of the medium have been demonstrated previously[4] to be independent of glutamic acid.

The present observation that established cell strains, of predominantly malignant origin, reduce the glutamine content of the culture medium is in accord with the report by Roberts and Borges[7] that tumour cells are generally distinguishable from normal tissues by their low levels of free glutamine. It should also be pointed out that the present status of the established cell strains is somewhat uncertain. Those now available, whether of normal or malignant origin, appear to possess certain malignant characteristics, and it is considered that alterations in cell type or properties have occurred during the period preceding their establishment as cell lines[8,9]. The present observation that such cell lines can utilize glutamine may be interpreted, accordingly, either as a possible metabolic difference between normal and malignant cells, or as a possible alteration in cell metabolism associated with the establishment of permanent cell lines in tissue culture.

We wish to thank Dr. S. F. Kitchen, Dr. R. C. French, and Mr. L. F. Guerin, of the Virus Section of this Laboratory, for cultures of human kidney and human amnion and for monkey kidney tissue; and Dr. E. E. Osgood, of the University of Oregon, Portland, for the human leukæmic strains.

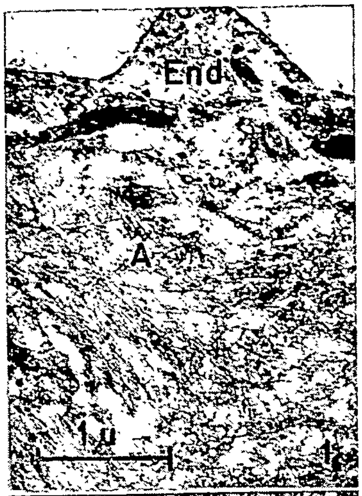
Electron Microscopic Observations on a Fibrous Component in Amyloid of Diverse Origins

AMYLOIDOSIS in man and animals may be associated with other disease entities or may occur spontaneously. The relationship, if any, of the different forms of amyloid has proved difficult to ascertain, and the chemical nature of amyloid has not been established. Previous studies have indicated that it is predominantly protein in nature[1,2] and have suggested that the protein is not primarily collagen[3] or γ-globulin[4]. No chemical differences have been noted in amyloid of different sources. The precise definition of the amyloid protein has, however, been hampered by its insolubility in organic solvents.

Polarization microscopy in this laboratory as in others[5] has demonstrated that unstained and congo red stained accumulations of amyloid of a variety of sources exhibit positive birefringence with respect to the long axis of the deposit. This suggests that amyloid is not as structurally amorphous as it appears in the light microscope. To explore this possibility, electron microscopic studies were undertaken.

The following materials were used: (1) kidneys of 6 rabbits with casein-induced amyloidosis obtained immediately at the time of killing; (2) skin and subcutaneous tissue biopsy material from a patient with proved primary amyloidosis; (3) kidney of a patient with amyloidosis of parenchymal organs (liver, spleen, kidney) obtained 3 hr. post-mortem.

The tissues were immediately cut into specimens about 1 mm.^{3} and were fixed in both Dalton's solution



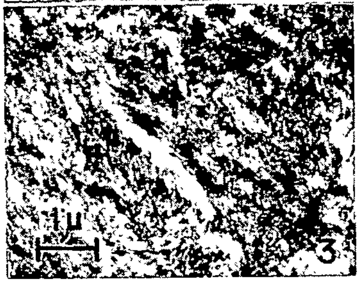


Fig. 1. Portion of rabbit glomerulus demonstrating amyloid fibrils in haphazard pattern. *A*, Amyloid; *End*, glomerular endothelial cytoplasm. (× *c*. 17,500)

Fig. 2. Portion of subcutaneous tissue biopsy of patient with primary systemic amyloidosis. Amyloid fibrils arranged in curved bundles. (× *c*. 23,500)

Fig. 3. Portion of renal tubular interstitial area of kidney obtained 3 hr. post-mortem. Fibrils in amyloid in swirls. (× 8,000)

and buffered osmium tetroxide in sucrose, then dehydrated in alcohol. Alternate specimens were put through 1 per cent phosphotungstic acid in absolute alcohol. The tissue was embedded in *n*-butyl methacrylate, and polymerized overnight with benzoyl peroxide at 60° C. Thin sections 250–500 A. thick were cut on a Porter–Blum microtome and examined in an *RCA-EMU-2B* electron microscope. Successive thick sections (up to 0·5μ thick) were cut from the same blocks and studied with the phase microscope; and, after staining, with the light microscope in order to determine the exact location of the amyloid. Formalin-fixed sections of the same material which had been prepared simultaneously with the osmium fixation were also cut, stained with hæmatoxylin and eosin, crystal violet, congo red and van Gieson dyes, to permit estimation of the amount of amyloid present. All three types of amyloid-containing tissues studied, bound congo red and exhibited metachromasia with crystal violet.

In the rabbit kidneys, the appearance of the amyloid was striking. It was localized between the basement membrane and the endothelial cell cytoplasm and in specimens fixed without phosphotungstic acid, had a fine granular appearance with delicate filaments running through it. In the material stained with phosphotungstic acid the filaments were more clearly defined and in several areas there was a suggestion of beading along the strands. The distribution of the filaments was either haphazard (Fig. 1) or, in areas near endothelial cell cytoplasm, in bundles. Although limitations imposed by sectioning prevented the precise delineation of fibril dimensions, they appeared to range in length from 1200 to 5000 A., and in width from 50 to 120 A.

The biopsy specimen of the patient with extensive primary amyloidosis also showed wavy bundles of delicate fibrils in the electron microscope. These correlated with the areas of amyloid as seen in the phase microscope and in stained sections. The dimensions were similar to those seen in the rabbit amyloid. The width varied from 70 to 140 A. and long strands up to 16,000 A. were measured. No cross-banding was apparent. These fibrils were often seen near collagen fibrils in the same section but were easily distinguished from them since the latter had a greater width and characteristic cross-banding. Fig. 2 demonstrates the delicate, wavy nature of the amyloid filaments as seen at a magnification of *c*. 23,500.

The amyloid in the kidney of the patient with parenchymatous involvement also demonstrated fine bundles of filaments similar to those noted above. Fig. 3 represents a 8,000-magnification of an area of amyloid in the renal interstitial area. The fine curved nature of the fibrils is again apparent.

Thus amyloid of diverse origin had similar submicroscopic structural characteristics. The fibrils as observed thus far appear to be morphologically distinct from collagen, thus corroborating previous chemical studies[3]. Further isolation and characterization studies of this fibrous element should contribute to our understanding of amyloid.

Support of these investigations has been received in large part from the National Institute of Arthritis and Metabolic Diseases, U.S. Public Health Services Grant *A*-1064 (*C*-3).

Relationship between Salinity and Breeding of *Anopheles gambiae* in North-Eastern Tanganyika

A FEATURE of interest in the transmission of malaria in the Pare area of Tanganyika, before residual spraying, was the low sporozoite rate in *A. gambiae*, infections of less than 1 per cent normally occurring. Two factors thought to contribute to the low sporozoite-rate were facultative feeding on cattle, and a low survival-rate in the vector[1,2]. A further possibility, that could not be excluded, was that the local strain of *A. gambiae* was also relatively resistant to infection or exhibited some innate difference in behaviour that reduced its chance of acquiring an infection, compared with strains in other areas. The existence of a low sporozoite-rate in salt-water *A. gambiae* on the humid coast of Tanganyika[3] gave rise to speculation as to whether the presence of saline soils in the Pare area was not associated there also with the low sporozoite-rate.

In the vicinity of rivers that descend from the South Pare Mountains, there are porous alluvial fans that are not saline. Surrounding these fans are much older impermeable soils from which rainfall and seepages from the mountains evaporate to a much greater extent, and are therefore saline. Salinification of the soils is particularly marked along the edges of fans where river seepages are held up by impermeable soils. 17 soil samples were obtained from different points along the valley between the South Pare and Usambara Mountains. The salinity of each sample was indicated by its conductivity in a 1–5 soil/water suspension at 25° C., and the results expressed as micromhos/cm. Conductivity of soil was 200 by a river, 950 to more than 3,000 in the swamp area, and more than 3,000 micromhos/cm. at the edge of an alluvial fan.

The chloride content of water in which *A. gambiae* was found breeding was estimated by the method of Sinton and Kehar[4], and the results expressed as parts of chloride per 100,000 of solution and as per cent sea-water chloride. Among 42 samples, the parts of chloride varied from 2·5 to 170 or, in terms of chloride concentration in sea water, a range of 0·13 per cent to 8·95 per cent. The distribution of saline breeding places coincided with that of saline soils. Parts of chloride were 2·5–5 near a river, 2·5–55 in the swamp area, and 20–170 at the edge of an alluvial fan.

Recently hatched larvæ from the eggs of 7 *A. gambiae* from huts, and 11 from outdoor box shelters, were subjected to Ribband's test[3] and none survived. Observations were then made, at 30-min. intervals for 8 hr., on mortality of recently hatched larvæ in a series of saline concentrations. The results (Table 1) show that the larvæ survived chloride concentrations equal to 30 per cent sea water for 8 hr., but died within 7½ hr. at 34 per cent.

Table 1. MORTALITY OF *A. gambiae* LARVÆ IN A RANGE OF SALINITIES

Parts Cl/100,000	1,450	1,050	850	800	650	550	525	500
Sea water (per cent)	77	55	45	42	34	30	28	26
Survival (hr.)	0·5	1·0	2·5	3·5	7·5	8·0	8·0	8·0

Ribbands[5] found that *A. melas* on the west coast could develop in 150 per cent sea water, whereas the maximum concentration in which freshwater *A. gambiae* underwent complete development was 37½ per cent sea water. Muirhead-Thomson[3] found evidence that salt-water *gambiae* at Dar es Salaam would not survive salinities higher than 83 per cent sea water, although they survived Ribbands's test. *A. gambiae* from Pare did not survive Ribbands's test or salinities higher than 34 per cent sea water. It is concluded that *A. gambiae* in the Pare area is typical freshwater *gambiae*, and that resemblances in sporozoite rate between *A. gambiae* in Pare, and salt-water *A. gambiae* on the east coast, are not related to the occurrence of saline soils in the former area.

We acknowledge with grateful thanks the help given us by Dr. T. E. Fletcher in providing apparatus and reagents for chloride estimations. We also owe thanks to Dr. D. Bagster Wilson for helpful criticism.

Relationship between Epiphytic Algal Species and their Macrophytic Hosts

EPIPHYTES on the submerged parts of macrophytes have long been studied, but mainly from the taxonomic point of view. Little is known about the relationship of epiphytes with their host plants, or more particularly, whether certain species of algal epiphytes are associated with certain species of macrophytes. From observations made in Scotland, Sudan and in Malaya, I think that there is possibly some association. Mention was made of this in 1955[1], but since then there seems to have been no published information concerning this aspect of algal ecology.

Field observations are often marred by the fact that it is difficult to separate the effect due to decay from the natural epiphytic flora on healthy growing parts. The answer to such problems is to use healthy plants completely free from epiphytes, and to watch what develops on them in a particular environment. The difficulties in getting such 'clean' plants are innumerable. Dissected growing points are very slow to develop, while seeds of aquatic plants are often difficult to germinate. The use of algicides, such as copper sulphate and potassium permanganate, may not suppress fungi as well unless used in such quantities as may damage the growing points of the macrophytes. A solution to the problem was found by using 'Katadyned' water, which contains free silver ions in active form.

The plants chosen, *Enhydrias angustipetala*, *Naias graminea* and *Utricularia* sp., were all plants common in paddy swamps and in the fish ponds at this Station. Young healthy shoots were washed with a jet of water to free them as much as possible from attached algae, and each species was then placed in a large jar of 'Katadyned' water to which had been added some 'Sterasyl' or silver-coated gravel to maintain the content of silver ions in the water. The new young shoots which grew were completely free from epiphytes, and they in their turn were detached and transferred to fresh 'Katadyned' water. In this way healthy 'clean' plants were obtained.

A good length of the younger shoots of each species was transferred to a large fish pond, and sunk by weighting the lower end with a stone. Each plant was protected by a wire cage to exclude macrophyte-eating fish, but not smaller animals such as Crustacea, Rotifera and Protozoa. The pH of the water was 6·9. At the end of a fortnight the plants had increased in size and were coated with epiphytes.

They were carefully lifted, rinsed in water to free them from loose material, and then preserved in 5 per cent formalin.

A quick observation showed that, apart from some loose filaments of *Mougeotia capucina* (Bory) Agardh, the main epiphytic flora consisted of the diatoms *Gomphonema*, possibly *G. gracile* E. and *Eunotia*, probably *E. pectinalis* (Kz) Rbh. var. *elongata* V.H. and also attached plants of an undetermined species of *Oedogonium* (since no reproductive stages). As wide a selection of leaves as possible was taken, avoiding only the very youngest newly opened ones, which were still devoid of epiphytes. Twenty leaves from each species were examined; in the case of *Utricularia* a leaf consisting of several leaflets. The approximate area of each leaf was determined, and a systematic count of the epiphytes made. The results were expressed as density per sq. mm., the diatoms as cells, *Oedogonium* as attached whole plants. As was expected, the older leaves bore the heavier crops of epiphytes.

Table 1. ANALYSIS OF DENSITIES OF *Gomphonema*

	Total	Mean	Variance	
Macrophyte	Σx	$\bar{x}$	σ^2	$\log_e(\sigma^2)$
Utricularia	280·94	14·05	205·0380	5·32301
Naias	40·91	2·05	2·4217	0·88438
Enhydrias	36·60	1·83	2·2520	0·81182

From the results given in Table 1 it seems at first glance that the density of *Gomphonema* is much higher on *Utricularia* than on the other two species of macrophyte. Applying Bartlett's test for χ^2 it can be shown that this difference is significant.

$$\chi^2 = B/C, \text{ where } B = kn.\log_e S^2 - n\Sigma\log_e(\sigma^2)$$

and $C = 1 + (k + 1/3nk)$

Then $\chi^2 = 108{\cdot}718/1{\cdot}023 = 106{\cdot}26$

For 2 degrees of freedom at the 5 per cent level $\chi^2 = 5{\cdot}99$.

The three *Gomphonema* communities cannot be drawn from one and the same population.

Comparing only *Naias* and *Enhydrias* for *Gomphonema* we have $\chi^2 = 0{\cdot}0496$. For one degree of freedom at 5 per cent level $\chi^2 = 3{\cdot}84$. There is therefore no difference between the density of *Gomphonema* on *Naias* and *Enhydrias*.

No *Eunotia* was found on *Utricularia*, so only *Naias* and *Enhydrias* need be compared.

Table 2. ANALYSIS OF DENSITIES OF *Eunotia*

	Total	Mean	Variance	
Macrophyte	Σx	$\bar{x}$	σ^2	$\log_e(\sigma^2)$
Naias	95·37	4·77	147·9761	4·99721
Enhydrias	1·42	0·07	0·0234	−3·75502

$\chi^2 = 135{\cdot}4$. For 1 degree of freedom at 5 per cent $\chi^2 = 3{\cdot}84$. There is therefore a significant difference between the densities of *Eunotia* on *Enhydrias* and *Naias*.

Since no *Oedogonium* was found on *Utricularia* and only one specimen on all the leaves of *Naias* examined, it is obvious that there is a significantly higher population on *Enhydrias*.

The above results suggest therefore that *Enhydrias* favours the growth of *Oedogonium*, *Naias* that of *Eunotia*, while *Utricularia* bears the heaviest density of *Gomphonema*. These experiments were only preliminary and of short duration, and further experiments will be necessary. However, nothing is known about the physiological relationship, if any, between the host plants and the epiphytes, nor is it known what determines which species of epiphyte shall develop. Should the associations prove true, they must play a very important part in the productivity of waters. In the case of algal-feeding fish, such as *Tilapia mossambica*, the epiphytic flora may play a very important part in its diet; since there is evidence concerning the varying digestibility of the different groups of algae, any factor that may determine which species predominate may be of vital importance in the culture of the fish. It would therefore be of great interest to learn if any other similar experiments and observations have been carried out elsewhere.

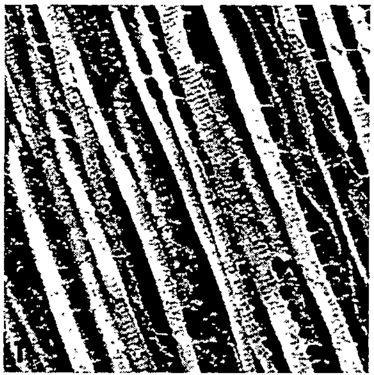
Improved Preservation of Tendon for Electron Microscopy through Wet Freeze-drying

MOST of the information on the fine structure of biological tissues as revealed through electron microscopy has been gained from sections of material fixed with buffered osmium tetroxide, dehydrated in alcohols, and embedded in plastics. The degree of preservation of intracellular detail attained by such handling has been in general very consistent, and the preparatory techniques have been widely accepted as adequate. It has become evident in our recent work that, while some extracellular structures are also regularly well preserved, others seem to suffer considerable damage when processed in like fashion. This has especially been true in the case of tendon, where the component microfibrils appear to become widely separated (Fig. 1). The particular tendons under study are found in the leg of the domestic turkey, and they are of interest to us because they undergo calcification. It is obvious that in order to investigate the relationships between collagen fibrils and mineral crystallites tissue preservation is of the utmost importance.

In our efforts to determine whether or not the structural pattern shown in Fig. 1 represents a true picture of the fibrillar organization of intact tendon, specimens were subjected to different preparatory methods for purposes of comparison. One possibility which was explored arose from a purely physiological observation reported by Mueller and Szent-Györgyi[1]. They noted that when muscle fibres were dehydrated by immersion for three weeks in chilled acetone, transferred to cold ethyl chloride for one week, and then dried in air, they could still be made to contract after rehydration. This suggested that a remarkably high degree of structural preservation must have been attained, and led us to investigate the potentiality of this procedure as applied in histological technique. We have found that when similar treatment with acetone and ethyl chloride is substituted for the osmium tetroxide fixation and alcoholic dehydration steps or for the fixation step alone, sections from methacrylate-embedded tendon fibres present a quite different appearance under the electron microscope (Fig. 2). The collagen microfibrils are in close contact and form wide bands with a definite alignment of the 640 A. striations. The sheet-like configuration resembles that seen in preparations of both teased native collagen fibrils[2] and reconstituted collagen[3].



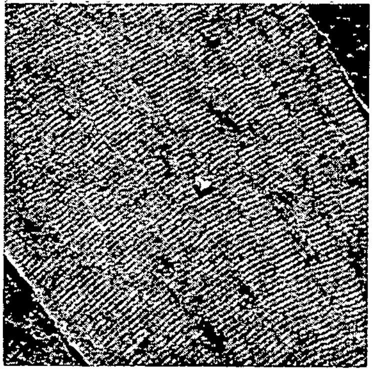


Fig. 1 (top). A thin section of uncalcified tendon from the leg of an 8-week old turkey; fixed in buffered 1 per cent osmium tetroxide, dehydrated in alcohol, embedded in methacrylate

Fig. 2 (below). A thin section of similar tendon which was simply treated with chilled acetone and ethyl chloride before embedding in methacrylate (both *c.* × 11,670)

We believe that this microscopic picture reflects a more intact state of tissue preservation, and more nearly represents the true structure of tendon fibrils than has hitherto been observed in sectioned material.

BACTERIOLOGY

Bacterial Action in Pond-stored Logs

Extreme porosity was found in sapwood lumber produced from logs of *Pinus ponderosa* and *P. lambertiana* which had been stored in a pond from one to several months. The extreme porosity resulted in substantial over-absorption of water-repellent preservative solutions which are normally applied to millwork, with consequent difficulties in painting and utilization.

Investigation showed that bacteria operating under anaerobic conditions rapidly increased the permeability of the sapwood without substantially affecting strength. The attack was characterized by: (1) removal of parenchyma ray cell contents; (2) corrosion and eventual destruction of parenchyma, particularly in ray tissue. With the assistance of Dr. E. McCoy of the University of Wisconsin, at least one group of the destructive bacteria was identified as *Aerobacillus polymyxa* (flax retting bacteria) and related species. Unidentified bacteria in pond-stored logs have been previously reported by Stutz and Stout (Western Pine Association)[1] in connexion with brown-stain development in pine.

Many bactericidal and related treatments were applied to pond water. In preliminary laboratory tests the most economic and practicable controls found to date are acidification of infected water with sulphuric acid or application of sodium chloride.

Subsequent surveys indicate that this attack is widespread, at least in mill-ponds in California, but not generally recognized. There were some indications that causative bacteria may be present in sound logs before entry into the storage pond but attack was only found in ponded logs.

This work will be reported in detail in the *Journal of the Forest Products Research Society*.

Cell-Wall Composition of *Leptotrichia* spp.

The status of the genus *Leptotrichia* has long been a matter of controversy, and in the current edition of Bergey's "Manual"[1] it is omitted completely. Nevertheless, there is no doubt of the existence in the oral flora of micro-organisms corresponding to the descriptions of *Leptotrichia*, and entirely distinct from other genera to which they have at various times been relegated by systematists. Two types are commonly found in the mouth, to both of which the name *L. buccalis* has been applied; these were distinguished by us as two species, *L. buccalis* and *L. dentium*[2]. Both are relatively large, filamentous, Gram-positive bacteria, but they differ considerably in morphology and metabolic characters, and the salient question arising from their recognition and distinction is whether they are sufficiently alike to be retained even in the same genus.

To the solution of this problem we have applied the technique of cell-wall analysis, according to the methods of Cummins and Harris[3], with certain modifications.

Sugars and amino-sugars were obtained from whole-cell hydrolysates, and analysed by descending, one-dimensional paper chromatograms using Whatman No. 1 paper and either *iso*propanol (160)/water (40) or phenol (80)/water (20) as solvents. Amino-acids were obtained from cell-wall fractions of cells broken by ultrasonic vibration, and chromatographed as for sugars, using *iso*propanol (70)/water (20)/acetic acid (10), or phenol (80)/water (20) + ammonia.

Leptotrichia buccalis and *L. dentium* yield exactly identical cell-wall amino-acid patterns, consisting of alanine, glutamic acid and DL- or DD-diaminopimelic acid as major components, and traces of glycine, serine, lysine and leucine. From our own comparative studies and the results of Cummins and Harris[4] this pattern appears to be representative of the genera *Nocardia*, *Mycobacterium* and *Corynebacterium*.

Sugar analyses showed arabinose and glucose as the major components of *L. dentium*, but only glucose in *L. buccalis*. Both gave small amounts of hexosamine (probably glucosamine) and ribose. The characteristic sugars of *Nocardia, Mycobacterium* and *Corynebacterium* are arabinose and galactose, which distinguish *L. dentium* from these genera. *L. buccalis* is even more clearly differentiated by its lack of arabinose.

From the evidence so far available it thus appears that the two species described by us[2] may reasonably be retained in the same genus, although it must be recognized that the taxonomic significance of amino-acid and sugar patterns in bacterial cell walls is yet poorly understood. There is already considerable variation in the literature regarding the taxonomic levels, that is, species, genera, etc., at which these patterns function as diagnostic characters. For this reason, the question of relationships between *Leptotrichia* and other groups still cannot be answered with any confidence. On the basis of morphology and cell-wall patterns, relationship to the *Nocardia, Mycobacterium, Corynebacterium* group of genera seems reasonable, whereas upon metabolic characters and cell-wall pattern, relationship with *Lactobacillus plantarum* is possible ; it may be that this apparent divergence in relationships will be reconciled by future work. No relationship to *Fusobacterium* or *Actinomyces* is indicated by our studies of cell walls in these genera.

Synthesis of Deoxyribonucleic Acid during the Division Cycle of Bacteria

In bacterial cultures undergoing synchronous growth, deoxyribonucleic acid has repeatedly been shown to be synthesized during part of the division cycle only (see review by Campbell, ref. 1). This could, however, be due to the physical or chemical operations used to induce synchronous division and need not reflect the normal pattern of synthesis of deoxyribonucleic acid. We have tested this possibility by examining autoradiograms of cells from uninfluenced cultures growing exponentially which had been exposed to thymidine labelled with tritium for short periods. Tritiated thymidine has already proved useful in studies of the mechanism of replication of deoxyribonucleic acid in bacteria[2]. The present experiments indicate that during normal exponential growth, synthesis of deoxyribonucleic acid is virtually continuous.

Two strains of *Escherichia coli* requiring thymine, namely, $15T^-$ (from the laboratory of Dr. S. S. Cohen) and *B*3 (from Dr. S. Brenner), were employed. These strains differ in morphology, mobility, rates of growth and sensitivity to penicillin. In addition, a wild-type strain of *Salmonella typhimurium* was used. Table 1 lists the media employed and the rates of growth obtained at 37° C. Tritiated thymidine (Schwarz Laboratories, Inc.) with a specific activity of 360 mc./m*M* was added to these media to a concentration of 3–5 μgm./ml. for *E. coli* and 12 μgm./ml. for *S. typhimurium*. Before addition of the labelled compound, exponential growth had been maintained at a constant rate for several generations in the presence of 0·5–1·0 μgm./ml. of unlabelled thymidine. Samples were removed at different times, treated with cold 0·5 *N* perchloric acid for 30 min., washed and resuspended in saline. This suspension was placed on agar blocks and, after the liquid had been completely imbibed, impression smears were made by touching the surface with 'subbed' glass slides (Ilford, Ltd.). The slides were covered with stripping film (autoradiographic film, *AR* 10, Kodak, Ltd.) according to the technique of Doniach and Pelc[3]. The time of contact with the film was selected to give an average of 3–5 grains per bacterium, and after development the bacteria were stained—through the film—with crystal violet.

Control experiments showed that the number of grains produced by the bacteria was reduced to the background value (about 1 grain/$100\mu^2$) after treatment with 100 μgm./ml. deoxyribonuclease for 30 min. at 37° C. Treatment with 0·5 *N* perchloric acid at 70° C. for 20 min. reduced the number of grains by 80–90 per cent, whereas the routine treatment with cold perchloric acid had no demonstrable effect. We therefore assume that nearly all the radioactivity which remains in the cells after extraction with cold acid resides in the deoxyribonucleic acid. Possible deoxyribonucleic acid-precursors of high molecular weight cannot be taken into consideration, since no chemical or genetic test has yet been developed which would distinguish such entities from deoxyribonucleic acid proper.

Table 1 summarizes nine experiments designed to show whether, during a fraction of the average generation time (see column 4), all or only part of the cells of a growing culture incorporate thymidine into their deoxyribonucleic acid. For each experiment the distribution of grains per cell was fitted to a Poisson distribution with the same mean value. This preliminary analysis revealed no systematic deviation from the Poisson distribution (see the *P* values of the last column), and it may therefore be

Table 1

Organism	Culture medium	Average generation time (min.)	Incorporation time as fraction of the average generation time	No. of cells counted	Average No. of grains per cell	Fraction of cells with zero grains	*P* per cent (of fit to Poisson distribution)
E. coli $15\ T^-$	Glucose–salts–thymidine	45	0·1	301	3·36	0·047	20–30
E. coli $15\ T^-$	Glucose–salts–thymidine	45	0·2	240	2·65	0·083	80–90
E. coli *B* 3	Glucose–salts–thymidine	48	0·1	257	2·58	0·112	5–10
E. coli *B* 3	Glucose–salts–thymidine	48	0·2	300	3·27	0·083	0·1–1
E. coli $15\ T^-$	Casamino acids–salts–thymidine	28	0·2	292	3·52	0·058	0·1–1
E. coli $15\ T^-$	Rhamnose–salts–thymidine	64	0·1	283	3·03	0·060	5–10
E. coli $15\ T^-$	Rhamnose–salts–thymidine	64	0·2	140	4·87	0·007	60–70
S. typhimurium	Glucose–salts–thymidine	50	0·2	203	3·29	0·044	80–90
S. typhimurium	Glucose–salts–thymidine	50	0·2	213	4·05	0·009	60–70

concluded that roughly equal amounts of tritiated thymidine are taken up by individual cells during a short period of exposure.

A detailed analysis, to be published elsewhere, has led us to the conclusion that synthesis of deoxyribonucleic acid takes place over more than 80 per cent of the division cycle; it was not possible to decide whether the rate of synthesis remains constant or increases during the cycle. The model on which the analysis was based allows for the fact that some of the cells divide during the period of incorporation of labelled thymidine, and it could be shown that such sources of error as trackiness in the autoradiograms and variation in the individual generation times do not invalidate the interpretation.

Our results indicate that the pattern of synthesis of deoxyribonucleic acid found in synchronous growth experiments is artificial, and great caution must therefore be exerted in interpreting data from such experiments in terms of the normal division cycle. The rapidly growing bacterial cells apparently differ, with respect to their synthesis of deoxyribonucleic acid, from animal and plant cells, where this process seems to be restricted to part of the interphase period.

Adaptation of Marine Bacteria to Growth in Media lacking Sodium Chloride

THE adaptation of marine bacteria to the ability to grow on ordinary nutrient media prepared with distilled water instead of sea water has been observed in stock cultures; but, paradoxically, procedures designed to acclimatize these forms have not been successful[1,2]. The techniques previously reported have involved successive cultivation of the organisms in media progressively diluted with distilled water. A possible reason for the failure of these trials seems to be the complex nature of the adaptive changes required to allow for the simultaneous reduction or omission of all the components of sea water. Accordingly, the possibility of adapting marine bacteria to growing on media prepared with a synthetic sea water lacking only sodium chloride has been tested.

The cultures employed were isolated from samples of water from the Atlantic Ocean (St. Augustine, Florida) and the Gulf of Mexico (Cedar Key, Florida). All cultures required media prepared with sea water, and their cells lysed when suspended in distilled water. None of the organisms grew in media prepared with synthetic sea water from which sodium chloride was omitted; but on the other hand, sodium chloride alone failed to satisfy their mineral requirements. The synthetic sea water employed was compounded as follows: sodium chloride, 2·4 per cent; hydrated magnesium chloride, 0·53 per cent; hydrated magnesium sulphate, 0·70 per cent; potassium chloride, 0·07 per cent. The organisms grew adequately in media prepared with this salt mixture. The nutrient base in all media was 'Trypticase' (B.B.L.) 1·0 per cent, supplemented with 1·0 per cent fresh yeast infusion (10 per cent yeast). Media from which sodium chloride was omitted contained no added sodium ions, contained less chloride ions and had a lower tonicity; consequently even this single omission posed a complex problem in adaptation.

A number of attempts to adapt these marine cultures to non-dependence on sodium chloride by the dilution of growing cultures failed. These efforts were arranged to permit the optimum opportunity for the induction of the entire population to non-dependence on sodium chloride similar to the reported behaviour of *Escherichia coli* toward increased concentration of sodium chloride[3]. On the other hand, when heavy suspensions of the cultures were plated on the nutrient media prepared with artificial sea water from which sodium chloride had been omitted, a small proportion of the cells grew and produced colonies. These were capable of growing in subsequent culture in the absence of sodium chloride. When similar aliquots were plated on nutrient media prepared with fresh water, no colonies were obtained from any of the cultures tested. The frequency with which the cells independent of sodium ions occurred was compatible with their resulting from mutational events (Table 1). From each of the cultures a representative adapted colony was selected, purified by streaking and was maintained in stock on the medium free from sodium chloride.

Table 1. INCIDENCE OF SODIUM CHLORIDE-INDEPENDENT CELL IN ORIGINAL CULTURES AND STABILITY OF ADAPTED STRAINS

Culture	Incidence of sodium chloride-independent cells in unadapted cultures*	Percentage of adapted cells reverting after growth in sodium chloride†
I	$1\cdot3 \times 10^{-8}$	68·0
II	$1\cdot2 \times 10^{-8}$	0·0
III	$6\cdot3 \times 10^{-8}$	99·2
IV	$3\cdot4 \times 10^{-10}$	99·6

* Incidence is calculated as the ratio of the viable count obtained on the medium lacking sodium chloride to that obtained on the medium prepared with complete synthetic sea water.
† Values are the percentage of cells not capable of forming colonies in the absence of sodium chloride.

Table 2. OSMOTIC FRAGILITY AND GROWTH IN SODIUM CHLORIDE-FREE MEDIA OF ADAPTED AND UNADAPTED CULTURES

Culture	Per cent lysis in distilled water*		Growth in sodium chloride-free medium†	
	Unadapted	Adapted	Unadapted	Adapted
I	79	22	0·04	0·31
II	50	12	0·02	0·35
III	57	29	0·02	0·30
IV	56	28	0·01	0·35

* Per cent lysis is the percentage reduction in optical density resulting when a standardized heavy suspension in sea water is diluted 100 times in distilled water. The standard of comparison is a similar dilution in sea water.
† The values recorded are optical densities of the cultures after 24-hr. growth.
Optical densities were measured by means of a Bausch and Lomb 'Spectronic' 20.

The adapted strains were osmotically less fragile than were the original cultures, although some lysis still occurred when the cells were suspended in distilled water. This residual fragility was not surprising since the medium retained a relatively high salt content despite the omission of sodium chloride. As would be expected, growth in media lacking sodium chloride was better with the adapted forms (Table 2). All the adapted strains were able to grow in media prepared with distilled water, although the initial colonies had apparently been unable to develop in such media. Thus it appeared that strains which had grown in the absence of sodium chloride had developed the additional capacity of growing in media prepared with distilled water. All the strains when grown in such media produced green or blue-green water-soluble pigments.

If the adaptation to non-dependence on sodium chloride in these isolates resulted from the selection of mutants, then logically the adapted character should be retained after being grown in the presence of sodium chloride. Accordingly, the adapted cells were grown in media prepared with sea water and were then tested for reversion. All but one of the cultures indicated some degree of reversion to the wild form, and in two cases it was quite marked (Table 1). This was reflected in the osmotic and growth properties of the cultures as well as a reduced percentage of cells independent of sodium chloride in the culture. These changes occurred during a single cultivation lasting 12 hr. The terminal cell population was about 10^{10} cells/ml. An obvious difficulty exists in the interpretation of these results, since the inclusion of sodium chloride in the medium was probably as rigorous a selecting force as was its omission.

The observations suggest, although by no means prove, that cultures of marine bacteria contain mutant individuals capable of developing in the absence of sodium chloride. Such cells are not able to initiate growth in the nutrient media prepared with distilled water, but require some other mineral component of sea water. For some reason as yet unexplained, the osmolysis of many marine bacteria usually does not occur in the presence of magnesium ions in the concentrations found in sea water[4] (that is, 0·05 M). As a possibility, it is suggested that such mutants growing in sea water media, although genotypically capable of growing in the absence of sea water, are phenotypically osmotically fragile. For their development in the absence of sodium chloride they must grow in the presence of magnesium ions to permit the initial maintenance of the cells. Once grown, such cells have the ability to develop in media prepared with distilled water. The testing of this hypothesis is planned.

GENETICS

Homozygosity and *S* Gene Mutation

The S locus governing gametophytic self-incompatibility in plants is particularly suited to mutation studies. Pollen grains having an unmutated allele are unable to grow through a style carrying the same allele. In contrast 'mutant' grains produce pollen-tubes which may overcome the incompatibility barrier. Thus, mutation can be scored simply as seeds produced in normally sterile matings, and then subjected to confirmation by progeny phenotypes. Studies of S locus mutations have been confined to heterozygous plants[2-4] as homozygotes are difficult to obtain in many species. Since pollen S phenotype is a gametophytic character, it has been implied that mutation frequencies of alleles in homozygous plants would simply reflect those of alleles in the corresponding heterozygotes. The present study does not support this postulate.

Five S alleles (S_1, $S_2 \ldots S_5$) in *Petunia inflata* L. were assembled into the corresponding five homozygotes and ten heterozygotes at both $2n$- and $4n$-levels. Homozygotes are obtained readily in this self-incompatible species by self-pollination of young buds prior to S gene action in the style. Results will be reported for the five $2n$ homozygotes and three of the $2n$ heterozygotes—S_1S_2, S_1S_5 and S_3S_4. Two or more plants were used of each genotype, where possible, comprising a total of 16 different plants and their clonal propagants. X-rays were delivered to flowers and buds of pollen-parent plants at 250 kV., commonly with a filter of 1/4 mm. copper and 1 mm. aluminium. Pollinations were made exclusively with unirradiated flowers as females, since appreciable ovular damage occurred in flowers treated pre-meiotically (54 per cent abortion at 500 r., 88 per cent at 1,000 r.). Plants were grown and pollinations entirely made in bee-free control chambers at 22·5° C. Results are summarized as proportions of incompatibly pollinated flowers which produced seed-containing pods. Incompatible matings included both self- (for example, $S_1S_1 \times S_1S_1$) and cross-pollinations (for example, $S_1S_3 \times S_1S_1$).

A most impressive feature of the results was the differential response of homozygous and heterozygous clones (Table 1). Homozygous plants rarely set seed in incompatible matings (about 1 seed per 100,000 viable pollen grains), whether irradiated or untreated. In contrast the heterozygotes produced seed-containing pods in 6·8 per cent of the incompatible matings of untreated males and up to 42·0 per cent of those with X-rayed males (Table 1). No significant differences were observed among genotypes within either group. An average of 5·1 seeds per pod was obtained from the 286 selfed pods on treated and untreated heterozygotes, while compatible crosses on the same plants ranged from 180 to 240 seeds per pod. The proportions of seed-containing pods on heterozygous plants varied greatly depending on the time of treatment (Table 1). However, there was no significant variation with time among X-rayed homozygous flowers (heterogeneity $\chi^2 = 9\cdot 2$, $P = 0\cdot 30$). Meiosis occurred about ten days prior to anthesis (range 9–11 days).

Buds treated after meiosis did not differ significantly from the controls in mutation output, in accord with Lewis's observations[3]. The low S mutability of such post-meiotic buds on heterozygous

Table 1. Percentages of incompatibly pollinated Flowers which produced Seed-containing Pods

* Number of days from X-irradiation to anthesis.

plants has been interpreted to indicate that S gene action occurred immediately following meiosis[2]. However, this low mutability in post-meiotic haploid cells would be accounted for if a major proportion of S mutation somehow depends on S allelic heterozygosity within the target cell. This sheds doubt on the validity of employing S mutation frequencies (in heterozygotes) to define the time of S gene action. An alternative argument is that S gene action in the pollen occurs as late as the second mitotic division—a timing which could account for the difference in place of inhibition of bi- and tri-nucleate grains[1].

The following mutation frequencies per million viable pollen grains were calculated from the data (11–12 days prior to anthesis is ±pre-meiotic interphase): 9·9, homozygote control; 21·4, homozygote—1,000 r. at 11–12 days; 84·0, heterozygote control; 1,320·0, heterozygote—1,000 r. at 11–12 days.

These values may serve as rough indices of mutation-rates. Variables influencing these calculations include: (*a*) the number of pollen grains, which ranged from 1,800 to 4,500 per pollination for the clones used; (*b*) pollen viability *in vitro*, which dropped to 46 per cent of control-rates in flowers treated between 9 and 16 days with 1,000 r. In addition: (*c*) seed sets averaged 3·0 for control pods, while pods from heterozygotes treated at 9 days or less averaged 3·0 seeds, from 9 to 14 days averaged 5·0 seeds and for greater than 14 days, 6·4 seeds. Finally (*d*) of the 36 'mutant' progeny grown approximately two-thirds have reacted as S mutants.

Twelve of these mutants studied have shown part inactivation of pollen, a phenomenon which led Lewis[3] to postulate that the S locus is bipartite with separable pollen and stylar units. One other mutant plant was of particular interest, for it reacted as if the mutant allele was a cross-over recombinant with the pollen activity of gene S_1 and the stylar activity of allele S_2.

These observations could be interpreted to suggest that the relatively high S mutability of heterozygous cells may occur as a result of genetic interchange. Equal crossing-over or gene conversion would be expected to produce mutants only in S heterozygotes, a significant possibility if the locus is a pseudoallelic aggregate or a composite of separable sub-units. Alternatively, if the S locus comprises synaptically equivalent stylar- and pollen-units, unequal crossing-over could lead to part mutation of pollen in heterozygotes by assembling on the same chromosome two alleles or pollen-units which interact by competition in the pollen (competition interaction leading to full self-fertility occurs in all ten heterogenic pollen classes of tetraploids derived from the heterozygous diploids studied). Unequal crossing-over also would produce partly deficient pollen gametes in both homozygous and heterozygous plants. It is hoped that a detailed investigation of mutant alleles will shed light on the relative significance of these events.

This investigation was conducted at Brookhaven National Laboratory under the auspices of the U.S. Atomic Energy Commission.

Possibility of Assortive Mating in the Arctic Skua

Data have recently been collected in Caithness and Shetland on the numbers of the different mating types, dark × dark, dark × pale and pale × pale, of the colour phases of the Arctic skua, *Stercorarius parasiticus*. Although on Fair Isle intermediates, very similar to darks, are recognized; in the remainder of these data, this distinction is not made: for this reason, the intermediates in the Fair Isle data have likewise been added to the darks.

The observations at present available are given in Table 1, together with the date and names of collectors. The Fair Isle data were extracted directly from the record books there.

Table 1

	$D \times D$	$D \times P$	$P \times P$
Fair Isle, 1954–58 (Williamson, K., and Davis, P. E.)	64	34	10
Foula, 1948 (Venables, L. S. V., and Venables, U. M. (ref. 1))	9	7	2
Unst, 1948 (Venables, L. S. V., and Venables, U. M. (ref. 1))	36	15	4
Yell and Fetlar, 1948 (Yeates, G. K. (ref. 2))	36	25	5
Noss, 1946 (Perry, R. (ref. 3))	21	9	7
Caithness, 1953 (Pennie, I. D. (ref. 4))	9	11	1
Totals	175	101	29

D, dark; P, pale

In the Caithness data, the single pale × pale mating was described as a pale × intermediate pair. The description of the intermediate, however, showed that this bird was in fact what would have been called a 'dusky' pale at Fair Isle. This means that the neck and belly are cream rather than white; but these matings have always produced apparently normal pale-phased chicks and are thus included with the pales: what are called 'intermediates' at Fair Isle lack the pale belly.

In the analysis given in Table 2, 2 × 2 contingency tests of independence have been employed: χ^2 for one degree of freedom with Yates's correction has been calculated.

Table 2

Locality	χ^2	Locality	χ^2
Fair Isle	1·99177	Yell and Fetlar	0·0078391
Foula	0·028800	Noss	5·04175
Unst	0·79781	Caithness	0·27320
	Total data	5·34064 (deviation χ^2)	

The χ^2 value calculated for all the data is thus found to be significant at just above the 2 per cent level. It is therefore important to test whether any significant heterogeneity is present. By summing all the separate χ^2 values, χ^2_{total} for 6 degrees of freedom is found to be 8·1412. The heterogeneity χ^2 is now obtained by subtracting $\chi^2_{\text{deviation}}$ from χ^2_{total}. We thus find,

$$\chi^2_{\text{het.}}\ (5 \text{ degrees of freedom}) = 2{\cdot}8005$$

This value clearly does not approach significance.

The conclusion to be reached from these results is that a strong possibility of a departure from random mating among the phases of the Arctic skua exists: a significant excess of like over unlike matings is present, thus indicating a tendency towards homogamous mating.

It is interesting to speculate on the advantages to be gained from this tendency towards homogamy. Fisher[5] says of homogamy in man: "Its principal biometric effects seem to be to increase the genetic variance produced by a given number of Mendelian factors with given gene ratios, and so to increase in a fixed proportion the intensity of the selection to which each is exposed". In this sentence, Fisher is, of course, discussing quantitative variation. It would seem likely, however, that homogamy involving major genes will act in a similar manner by affecting the modifiers of these genes and thus increasing the variability of the expression, especially of the heterozygote. This must lead to a more rapid evolution of dominance: indeed, at Fair Isle, it has been noted that dark appears to be semi-dominant.

Fisher also suggests that the causes of homogamy are scarcely to be distinguished from those which, in sexual preference, produce direct selective effects. Sexual preference might have evolved directly, by the lessening of competition among the more variable families; but there also appears to be the possibility of the evolution of sexual preference by a form of sexual selection. On Darwin's theory of sexual selection in monogamous birds, Fisher[5] says: "He [Darwin] supposes in effect that there is a positive correlation in the females between the earliness with which they are ready to breed, and the numbers of offspring they rear, variations in both these variates being associated, as Darwin suggests, with a higher nutritional condition. Whether this is so in fact it is difficult to say, but it should be noted that the dates of the breeding phenomena of a species could only be stabilized if birds congenitally prone to breed early did not for this reason produce more offspring. The correlation required by Darwin's theory must be due solely to non-hereditary causes, such as chance variations of nutrition might supply. Whether or not there is such a correlation, it would seem no easy matter to demonstrate".

If the sexual preference in question were correlated with early breeding, then clearly the evolution of this preference would prove fairly rapid. On the other hand, if no such correlation were initially present, sexual selection might still result in the enhancement of the sexual preference. The early females must have a wide choice of mates not only in respect of preference for like-phased matings but also for characters like quality of display, physique, or other plumage characteristics. Thus, though it is true that if the proportion of females tending to homogamy is the same in late as in early breeding birds, then the same proportions in the phases of the males will be available to the late as well as the early females: yet, the males left for the late females may be deficient in other respects, thus leaving the late females with a more limited choice of mates; moreover, random fluctuations in the numbers of the different phases must further cut down the choice. This theory demands that there should be congenital variations in the sexual preference in relation to breeding time. It should be noted that in the Arctic skua, birds generally pair for life—divorces are fairly rare—and so this form of selection must be much slower than in a species in which new pairs are formed each year.

Recoverable Lethal Mutations in *Drosophila* Sperm

In an experiment with fractionated irradiation of *Drosophila melanogaster* males Lüning and Hannerz[1] showed that there was induced the same rate of chromosome breaks at anoxia as in air, but that there was a recovery after irradiation at anoxia which, however, could be blocked by a fraction of irradiation in air. Lüning and Söderström[2] extended these observations to sex-linked recessive lethals and concluded that there existed a similar recovery process among this type of mutations as among chromosome breaks.

Irradiation at anoxia induced changes which could either result in a recessive lethal mutation or reversion to a non-lethal state which could not be distinguished from the original state. If a second fraction of irradiation was given in air within 15 min. after the treatment at anoxia the recovery process was blocked and a rate of recessive lethals was obtained equal that when the whole of the dose was given in air.

In a paper presented to the second Geneva Conference on the Peaceful Uses of Atomic Energy, Lüning showed that the recovery of chromosome breaks could be blocked if the second fraction (in air) was given within 30 min. but not when given on later occasions.

From these results it was concluded that the recovery occurred between 30 and 40 min. after irradiation, and when it had recovered the subsequent irradiation in air had no influence.

A similar analysis using recessive lethals would be of great interest. First, the question arose whether there could be determined a time within which recovery occurred. The establishment of such a borderline should also give a proof of the existence of recoverable mutation processes. Secondly, it was desirable to know whether this borderline agreed with that obtained from chromosome breaks.

In order to study this, the conventional Muller-5 technique was used. 3–4 days old *cv:sc*^{8}*Y* males were given nitrogen for 15 min. before and during the treatment (5 min. = 2,750 r.). The males were then divided into four groups. After varying intervals, they were irradiated in air (3 min. = 1,650 r.). The intervals were chosen to test agreement with the recovery process in chromosome breaks, namely, 15, 30, 40 and 50 min. The males were mated for 6 hr. The females were then allowed to oviposit for two three-day periods. The procedure was then the conventional one. The criterion on lethality has been at least 12 *M5* males but no *cv* males. Some cultures were analysed also in F_3.

Four repeats were made which gave consistent results and for that reason are combined in Table 1.

As is seen from Table 1 the series falls into two groups with the borderline between 30- and 40-min. intervals, which agrees with that from chromosome breaks. Furthermore, the two series with intervals 15 and 30 min. are consistent and significantly higher than the series with 40 and 50 min. interval. This result is in agreement with the expectancy if the

Table 1

Interval	Recessive lethals	Tested X-chromosomes	Recessive lethals (per cent)
15 min.	222	2,154	10·3
30 min.	220	2,026	10·9
40 min.	161	2,049	7·9
50 min.	172	2,192	7·8

recovery of potential recessive lethals occurred between 30 and 40 min. after irradiation at anoxia. The establishment of this borderline may be taken as a proof that there may exist recoverable mutations, although it does not give any information about the ratio of mutations which has this possibility.

PSYCHOLOGY

Effects of Independent Variations in Stimulus and Response Probability

The time taken by human beings to react to one of a number of possible signals increases with the number of alternatives involved. The effects of jointly varying stimulus and response uncertainty have been long known and adequately discussed[1,2]. In the present investigation these were varied independently, by using situations where the same response was required for a number of stimuli. The number of responses, and the ratio of response/stimuli were varied.

Card sorting was used as a convenient task for a pilot study. The subject turned and dealt cards from packs held in the non-dominant hand, on to a number of piles. Each pile represented a group of stimuli to which the same response was required. The stimuli were letters and figures (72 point) stencilled on the cards in indian ink. Packs were made up for each condition, so as to vary the number of different symbols for each pile; the number of piles was of course constant for each condition.

Four conditions of response uncertainty were used, four packs for each condition being employed. In one condition packs were to be sorted into two piles, there being one, two, four and eight symbols per pile. Cards were sorted into letters, or figures.

The other conditions used four, six and eight piles, with response/stimulus ratios of 1/1, 1/2, 1/3 and 1/4 in each case. Ten subjects were tested on condition one, and a fresh batch of twelve on condition two. Four trials were given on each pack (that is, each response/stimulus ratio). A third batch of nine subjects was used on the six- and eight-pile conditions. Six of these had eight trials with each pack; the remaining three had sixteen trials with each pack. Sorting time was taken with a stop-watch. Packs were given in random order. For the first sortings in each condition, but never afterwards, indicator cards were attached to the boxes into which the cards had to be sorted. The order of the boxes from left to right was varied randomly for each subject. Subjects were students at a teachers' training college, and female shop assistants. No significant differences appeared between these groups.

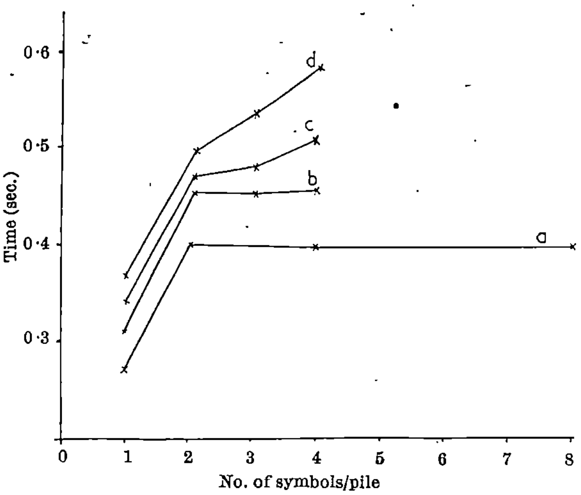

Fig. 1. *a*, 2-pile condition; *b*, 4-pile condition; *c*, 6-pile condition; *d*, 8-pile condition. Decision time/card was obtained by subtracting mean movement time, obtained individually for each subject, from the mean sorting time for each condition

The results of these tests are shown below. In condition one there was a marked significant increase in time between pack I and pack II. Times for packs II, III and IV did not differ. In condition two the results were similar. In condition three the most striking difference remains that between packs I and II. There is a non-significant difference between packs II and III, and a significant ($P < 0{\cdot}02$) increase between pack III and pack IV. In the fourth condition there are highly significant differences between all packs. The most striking is that between pack I and pack II. The results of the three practised subjects on the last conditions were of the same pattern.

In the last three conditions digits had been sorted into two of the piles. It was felt that the results might have been partly explained by the diminishing effect of the figures/letters dichotomy as the number of piles increased. Accordingly, the two- and four-pile conditions were repeated on six subjects practised in earlier trials using letters only. After eight trials on each pack in both conditions, the results showed the same pattern as the earlier tests. The increased practice necessary suggests that the figure/letter dichotomy had been used by the subject in earlier tests.

The results were still open to the interpretation that, despite the precaution of giving packs to the subjects face down, a small increase in reaction time with increase of stimuli/response was masked by subjects 'taking up the slack', and overlapping movement and decision-time to some extent. A choice reaction-time apparatus was used for investigating this, push buttons representing piles, and stimuli being projected on to a screen before the subject. Individual reaction-times were measured with a 'Dekatron' timer. Six subjects were used on the two-pile condition (letters/figures) and four on a four-pile condition (2 letters/figures, 2 letters only). The results gave the same pattern as the card sorting tests. In the four-pile condition considerable practice was necessary (500 presentations for each response/stimulus ratio) before this pattern emerged.

These results suggest that there are certain limits within which the response-time to groups of stimuli is dependent on the number of possible responses, rather than on the number of different alternative stimuli to which each response is to be made.

This work was carried out under a Department of Scientific and Industrial Research studentship, and the supervision of Mr. D. E. Broadbent.

Challenger Society (at the Linnean Society, Burlington House, Piccadilly, London, W.1), at 5.45 p.m.—Annual General Meeting, followed by Dr. G. S. Carter: "The Conditions of Evolution in the Deep Seas".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Mr. G. de Q. Robin: "Antarctic".

Wednesday, April 29—Thursday, April 30

Institution of Electrical Engineers (in conjunction with the British Nuclear Energy Conference, at Savoy Place, London, W.C.2.—Convention on "Thermonuclear Processes".

Thursday, April 30

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Mr. R. L. F. Boyd and Mr. N. D. Twiddy: "Electron Energy Distributions in Plasmas"; Mr. R. L. F. Boyd and Mr. J. B. Thompson: "The Operation of Langmuir Probes in Electro-Negative Plasmas".

Institute of Information Scientists (at the Berners Hotel, 10 Berners Street, London, W.1), at 6 p.m.—Symposium on "The Adaptability of Experience—an Inquiry into the Subject Qualifications Needed for Information Work". Chairman: Mr. L. J. H. Haylor. Speakers: Miss I. M. Slade, Mr. A. Gordon Foster, Mr. C. W. Hanson and Mr. F. Newby.

Institution of Electronics (in the Assembly Hall of the University of London Institute of Education, Malet Street, London, W.C.1), at 7 p.m.—Mr. G. H. Byford: "Measurements in Aviation Physiology".

University of London (at the Swanley Hall, Withersdane, Wye College, near Ashford, Kent), at 8.15 p.m.—Dr. I. A. Galloway: "Recent Advances in the Study and Control of Animal Virus Diseases".*

Friday, May 1

British Psychological Society, Occupational Psychology Section (in the Department of Psychology, Birkbeck College, Malet Street, London, W.C.1), at 1 p.m.—Mr. John Annett: "Problems of Training".

Antiquarian Horological Society (at the Science Museum, London, S.W.7), at 7 p.m.—Annual General Meeting.

Saturday, May 2

Association of Agriculture (at Senate House, University of London, W.C.1), at 10 a.m.—Conference on "Further Aspects of Animal Physiology".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Lecturer (with a degree in botany with some zoology) in Biology—The Registrar, University College of North Staffordshire, Keele, Staffs (April 30).

Assistant Lecturer (preferably with special interests in economic geography and statistics) in the Department of Geography—The Registrar, The University, Leeds (May 1).

Assistant Librarian (Chartered Librarian)—The Establishments Officer, Zoological Society of London, Regent's Park, London, N.W.1 (May 1).

Lecturer (with a good honours degree and preferably special qualifications in servo-mechanisms applied to electrical machines) in Electrical Engineering—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 1).

Assistant Lecturer (with a good honours degree in psychology and preferably some experience of teaching and research) in the Department of Psychology—The Registrar, The University, Leeds 2 (May 2).

Experimental Officer or Assistant Experimental Officer (with analytical experience) in the Technical Chemistry Department, to work on problems connected with grass and milk—The Secretary, The Hannah Dairy Research Institute, Kirkhill, Ayr, Scotland (May 2).

Lecturer in Physics and/or Chemistry—The Principal, Borough Road College, Isleworth, Middlesex (May 4).

Senior Scientific Officer (with a science degree of a university in the United Kingdom with passes in biochemistry, zoology, botany, etc., and preferably five-years experience in serology in the Health Service basic grade of Scientific Officer)—The Director, Regional Blood Transfusion Centre, Churchill Hospital, Headington, Oxford (May 2).

Lecturer in Physiology—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 4).

Assistant Lecturer (with a good honours degree in zoology and special interests in parasitic protozoa) in Zoology—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 5).

Lecturer in Biochemistry—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 7).

Lecturer (with a good honours degree and preferably a special interest in the field of numerical analysis) in Applied Mathematics—The Registrar, King's College (University of London), Strand, London, W.C.2 (May 7).

Assistant Lecturer (preferably with a special interest in systematic botany) in Botany, and a Tutorial Assistant in Geology—The Registrar, University College of Wales, Aberystwyth (May 8).

Lecturer or an Assistant in the Department of Mathematics—The Secretary, The University, Aberdeen (May 9).

Lecturer or Assistant Lecturer (Veterinary Surgeon) in Veterinary Pathology—The Secretary, Royal Veterinary College (University of London), Royal College Street, London, N.W.1 (May 9).

Research Fellow in the Department of Chemistry, for work on heterogeneous catalysis—Prof. C. Kemball, The Queen's University, Belfast (May 9).

Senior Lecturers (with a good university degree in requisite subject, considerable postgraduate experience in research and/or teaching, and conversant with tropical work in the appropriate subject) in *(a)* Horticulture, *(b)* Animal Husbandry and *(c)* Poultry Husbandry at Kumasi College of Technology—The Council for Overseas Colleges, 12 Lincoln's Inn Fields, London, W.C.2 (May 11).

Lecturer in Education, and Assistant Lecturers in Biochemistry and Physiology—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 14).

Research Demonstrators in Physics, Zoology, Geology and Mining; and a Research Assistant in Engineering—The Registrar, University College of South Wales and Monmouthshire, Cathays Park, Cardiff (May 14).

Lecturer (preferably with qualifications in the comparative physiology of invertebrates), and an Assistant in the Natural History Department—The Secretary, The University, Aberdeen (May 15).

Research Assistant (Physical Chemist), for work with organometallic compounds—The Secretary, The University, Exeter (May 15).

Research Fellows (2) in the Department of Medical Chemistry, John Curtin School of Medical Research, Australian National University—The Secretary, Association of Universities of the British Commonwealth, 36 Gordon Square, London, W.C.1 (Australia, May 31).

Biochemist, Scientific Officer or Senior Scientific Officer grade (with a first- or second-class honours degree in biochemistry, and preferably postgraduate experience), to work on biological methods of preparing organic compounds labelled with radioactive isotopes—The Personnel Officer, Radiochemical Centre, U.K.A.E.A., Amersham, Bucks.

DEMONSTRATORS, INSTRUCTORS and ASSISTANT PROFESSORS IN THE DEPARTMENT OF PHYSICS, University of British Columbia, Vancouver—Dr. G. M. Shrum, c/o British Columbia House, 1–3 Lower Regent Street, London, S.W.1.

LABORATORY TECHNICIAN (with bacteriological or virological experience), for virus research—The Medical Superintendent, Common Cold Research Unit, Harvard Hospital, Salisbury, Wilts.

LECTURER (physicist with experience in X-ray crystallography, a knowledge of electronics and control mechanisms, and preferably previous experience in the rubber field) IN RUBBER PHYSICS—The Clerk to the Governors, National College of Rubber Technology, Northern Polytechnic, Holloway Road, London, N.7.

MASTER TO TEACH MATHEMATICS up to university scholarship standard—The Headmaster, Framlingham College, Framlingham, Suffolk.

MASTER TO TEACH PHYSICS to advanced level—The Headmaster, Malvern College, Worcestershire.

MATHEMATICS TUTOR (honours graduate in mathematics), to prepare to University of London degree standard—The Science Director, University Correspondence College, Burlington House, Cambridge.

RESEARCH PHYSICIST (preferably with experience in the use of ultra-high vacuum systems or in the chemical physics of surfaces) IN THE DEPARTMENT OF PHYSICS, for work which will involve electrical measurements applied to the study of surface contamination processes on semiconductors—The Professor of Physics, University of Reading, Physics Research Laboratories, Upper Redlands Road, Reading.

SCIENTIFIC ASSISTANT (ABSTRACTOR) (with a degree in agriculture or natural science, and a knowledge of languages)—The Director, Commonwealth Bureau of Pastures and Field Crops, Hurley, near Maidenhead, Berkshire.

SCIENTIFIC OFFICER (BOTANIST or AGRONOMIST), to work on the plant species and cultural conditions giving the best yields in the large-scale separation of leaf protein—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

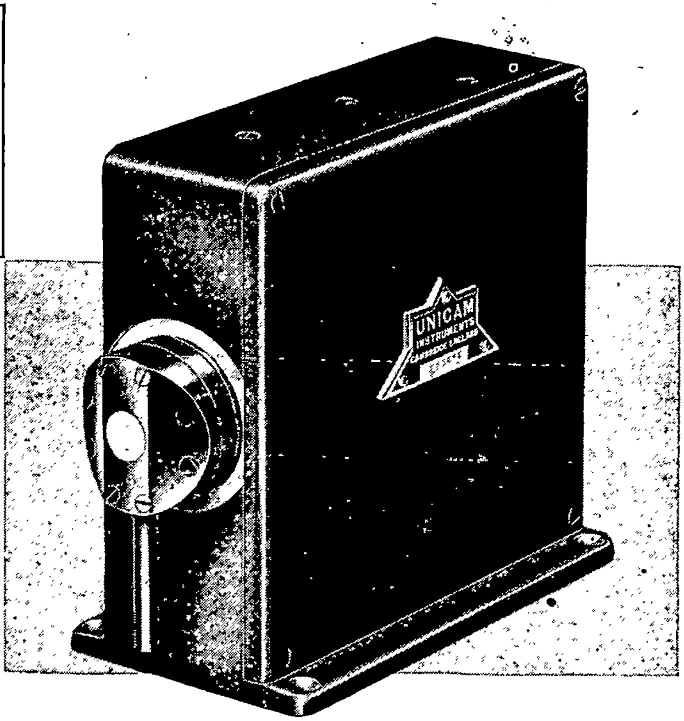
INFRARED DETECTOR



*sensitive
from
Visible
to
Microwaves*

The operation of the Golay Detector is based upon the expansion of a gas of low thermal conductivity in contact with a non-selective heat absorbing membrane. The cell in which the gas (normally Xenon) is sealed has at one end a mirror membrane operating in a photoelectric amplifier system in such a way that the light intensity at the photocell varies directly with the gas expansion.

One of the major advantages of this system is a uniform sensitivity over a wide range of wavelengths. With suitable window material the Detector can be used to measure radiation intensities from visible light out to the microwave region. The adjoining table shows recommended window materials for specific wavelength regions.

The Detector can be delivered from stock with the following windows—KBr, Quartz, KRS-5, CsBr.

We shall be pleased to quote for alternative windows, for the Detector alone or for the full equipment including electronic and chopper units.

TABLE OF WINDOW MATERIALS

Material	Approximate useful wavelength limits
KBr	from visible to 26 μ—27 μ.
CsBr	„ „ „ 35 μ—40 μ.
CsI	„ „ „ 45 μ—50 μ.
Quartz (0.25 mm thick)	„ „ „ 3.5 μ and from 45-50 μ to microwaves.
*Arsenic trisulphide	„ „ „ 10 μ.
*KRS-5	„ „ „ 35 μ.

*These two salts are non-hygroscopic but introduce some energy losses.

SCIENCE AND TECHNOLOGY IN THE UNITED STATES

THE appointment of Dr. J. R. Killian as special assistant for science and technology to President Eisenhower and the expansion of the activities of the National Science Foundation which followed swiftly on President Eisenhower's message to Congress of January 27, 1958, have been welcomed as facilitating Anglo-American co-operation and strengthening the organization of the Western world both in science and in defence. The essential ideas for these developments are to be found in reports issued earlier, notably in Dr. Vannevar Bush's report, "Science—the Endless Frontier", and the Steelman report, "Science and Public Policy" in the United States, and in the Barlow report on scientific staff in Great Britain. The United States is now, indeed, giving effect to ideas which in Great Britain have found expression in the establishment of the Advisory Council on Scientific Policy and the Defence Research Policy Committee, for example.

The address on "Science and Public Policy" which Dr. Killian delivered on December 25 to the American Association for the Advancement of Science shows how vigorously the Federal Government is implementing the new policy and how much has already been done to strengthen the position of both science and technology in the United States. This first report of Dr. Killian on the work of his office and of the President's Science Advisory Committee[*] is of great interest to the scientist and technologist in Britain, not only as summarizing what has been done but also from the point of view of eliminating weaknesses in our organization which have become apparent during the past year or so. Reference has indeed already been made in these columns to the report of the Science Advisory Committee's Panel on Scientific Information. This address, and the report of the Committee's Panel on Research Policy, to which Dr. Killian refers in detail, provide ample evidence to justify Dr. Killian's claim that the President's proposals have already been translated into action.

The expansion of the National Science Foundation, the available funds of which have been increased from 50 million dollars in 1958 to 136 million in 1959, may be appropriately left for consideration with the Foundation's latest annual report, merely noting Dr. Killian's view that it is now one of the Government's major means for advancing science and supporting basic research. Next, Dr. Killian notes the creation, under the Department of Defence Reorganization Act, of a new post of Director of Research and Engineering in Defence, and of the Advanced Research Projects Agency, to sponsor long-range research for defence and to undertake projects of common interest to the military Services. The former appointment indicates the importance now attached in the United States to the formulation at a high level of research and development defence policy and to the supervision of an overall programme. Besides this, the National Aeronautics and Space Administration has been created to provide a civilian-directed and civilian-oriented programme of space science and exploration, including research support for military aeronautics and space programmes, with a National Aeronautics and Space Council, advisory to and presided over by the President.

This new pattern of organization of scientific and technological research in the United States and of advisory service to the Government is quite distinct from the structure existing in Great Britain, but there are some similarities. These similarities are perhaps more marked in the work of the Science Advisory Committee and in the recently established Federal Council for Science and Technology, while on the educational side, under the National Defence Education Act, measures have been taken to strengthen science education that are probably more vigorous than those yet adopted in Britain. Likewise, the recent appointment by the State Department of seven scientific attachés suggests that the United States Government is giving more weight to such appointments than the British Government has yet done in spite of the recommendations of the Advisory Council on Scientific Policy.

Dr. Killian emphasizes that neither he, nor the Science Advisory Committee, has any executive responsibilities. Like the Advisory Council on Scientific Policy in Britain, their functions are purely advisory and they do not even share such responsibilities for the decision of policy as fall on the Lord President of the Council. They are charged with providing the best scientific advice and with making recommendations for the advancement of science and technology in the United States, especially by the Federal Government and in matters relating to security and welfare. A principal function is to provide a communications centre for science in the Federal Government, and thus to facilitate intercommunication among various scientific activities within the Government and between the civilian scientific community and the Government.

As in Britain, this is achieved to a considerable extent by the common membership of committees, as well as by the rotation of much of the membership, while the group of panels organized under the Science Advisory Committee enlist the advice and services of a very wide range of experience and knowledge, numbering at present about seventy-five scientists and engineers. Moreover, the Special Assistant for Science and Technology is invited to attend meetings of the National Security Council and the Cabinet, and, when appropriate or requested, to present the views and findings of the Science Advisory Committee. Objective scientific and technological advice can thus be presented effectively at the highest level of government, and it would appear probable that the United States has now a more effective means than Great Britain for ensuring that science and technology play a direct and creative part in formulating public policy. Moreover, particular attention is being given to the problem of placing at the disposal of the Government the creative powers and talent of the younger scientists and technologists, without handicapping either their professional development or their creative work in science and technology.

---

[*] A Statement by the President, and Strengthening American Science: a Report of the President's Science Advisory Committee. Pp. iii+36. (Washington, D.C.: Government Printing Office, 1958.) 20 cents.

The principal recommendation in the report, "Strengthening American Science", of the Science Advisory Committee's panel on research policy is the establishment of a Federal Council for Science and Technology to advise the Cabinet on those aspects of the Government's programme which require interdepartmental and Government-wide co-ordination and policy, and which affect science as a whole. The President has already authorized an executive order establishing this Council, and, as recommended by the Committee, membership of the Council will include representatives of the departments and agencies which have substantial research activities, and these representatives will be drawn from the policy-making level. The Committee suggested, for example, that the Council should include the Director of the National Science Foundation, the Commissioner of the Atomic Energy Commission, the Administrator of National Aeronautics and Space Administration and the Director of Defence Research and Engineering; but the Council will be able to call for advice from the Science Advisory Committee, the members of which are largely drawn from outside Government service.

In constitution and membership, the new Council thus appears to be drawn from a higher level than the Council for Scientific and Industrial Research in Britain, and for that reason may well prove a more effective instrument for concerting and co-ordinating Government policy in scientific and technological matters and in all national concerns where such factors are important. The Council is specifically to consider problems and developments in science and technology which affect more than one department or agency, and to recommend policies and other measures to promote the more effective planning and administration of Federal scientific and technical programmes. To that end the Council is to prepare a projection of the programme costs required to meet Federal needs, including both capital and man-power, and to consider the level and type of research financed by the private sector of the economy. It is also to promote effective utilization of Government resources and full co-operation among Government agencies, as well as consider and recommend measures for implementing policy decisions affecting the administration and conduct of Federal programmes in science and technology.

As thus conceived, the new Council, while still advisory, like the Advisory Council for Scientific Policy in Britain, appears to have functions going beyond those of the latter, and much further than those of the Council for Scientific and Industrial Research; and, as already noted, the higher level at which its membership is linked with Government may make it more influential and effective. Much will depend, none the less, on how clearly its advice and recommendations are understood by the Government; but scientists and technologists could scarcely expect their advice to be presented at a higher level. Moreover, the structure proposed appears to be reasonably flexible and to avoid the excessive centralization of authority that can be so inimical to the obtaining and presentation of the best scientific and technical advice.

It remains to be seen how far in practice these new arrangements will solve for the American scientist and technologist the difficult problems of power and responsibility, but they seem to afford reasonable prospect of the scientist and technologist exerting effective influence on public policy. It is not expected that the new Council will solve all the problems in managing research conducted by the Government, but it should assist Government departments in the United States to strengthen their own laboratories and to ensure a fuller and more economic use of their scientific resources. Moreover, the Panel on Research Policy is particularly concerned with the financing and planning of such highly expensive research equipment as particle accelerators in nuclear physics, and the research institutes which are needed or have been proposed in various fields. It recognizes the importance of considering carefully the relation of such institutes to the universities, and the danger of weakening the universities if unsound planning draws away from them too many research workers.

In this connexion, too, the Panel stresses the importance of greater emphasis on basic research. At present about 6 per cent of the U.S. Government's total budget for research and development of more than 5,000 million dollars in 1959 is earmarked for basic research, and the Panel is convinced that more vigorous support of basic research during the past decade would have paid rich dividends in reducing the cost of development. Stress is laid on nurturing new scientific fields and strengthening those, like meteorology, which are assuming new importance. Geology, geophysics, oceanography, radio astronomy, materials research and combustion are also mentioned as needing increased support and effort.

With its limited resources, Great Britain needs to select even more carefully than the United States the objectives of her research effort; this is a task to which the Council for Scientific and Industrial Research should be giving attention before reaching its decisions about the work of its own research stations. Had there been evidence of such a wider view, particular decisions like those taken in regard to fuel research and the discontinuance of *Fuel Abstracts* might have been less open to challenge. In directing attention last year to the need for the creation of new institutions for fundamental research in particular fields or sub-fields of science, the National Science Foundation stressed the importance of obtaining ample evidence where it is thought that existing facilities are inadequate or inappropriate, and it is no less important in closing down work in a particular field to be sure that appropriate facilities exist elsewhere.

The Panel on Research Policy in this report discusses also the problem of sponsored research in non-Government institutions and recommends more consideration of programme grants as a means of reducing the potential growth of Government administration and providing greater freedom for the scientific community to direct the work. It also recognizes the importance of the independent research foundation and private industry, and the need to avoid discouraging such support of research. The climate as well as the means have to be created whereby ideas which are challenging and sound but unconventional and difficult can be hospitably considered and encouraged.

Dr. Killian refers next to the activities of a Panel on Science and Technology in Foreign Affairs which has been concerned notably with aid to under-developed countries, the re-establishment of the posts of scientific attachés, and the creation of the necessary atmosphere for effective interchange of ideas and international scientific co-operation. Again, he describes at some length the study, by the Panel on Science and Engineering Education, of the objectives and needs of that part of the educational system which is responsible for supplying adequate numbers of first-rate scientists and engineers and achieving a high degree of scientific literacy. This Panel was convinced that some of the major challenges facing the United States to-day are on the intellectual front and that, in the long run, a greater desire to learn and increased respect for intellectual excellence may be essential to national survival—a view which Dr. Warren Weaver has elaborated in an article in *The Scientific American.*

This may be equally true of Great Britain, and it is certainly true that, in considering our educational problems at any level, we, too, should be considering how such objectives can best be achieved. From this point of view alone, it is of interest to note three specific conclusions reached by this Panel. First, because in the immediate future the rising number of students will outstrip the supply of teachers, it is necessary to find new ways of increasing the effectiveness of existing teachers. Secondly, more attention should be given to the quality and content of courses and curricula in science. Thirdly, in the judgment of the Panel, in relation to national responsibilities and opportunities in science, the United States has too few first-rate institutions of higher education in science and engineering, so that there is real danger of overloading the few departments of the highest quality.

The Minister of Education, Mr. Geoffrey Lloyd, remarked in the House of Commons on March 12 that his main impression on his recent visit to the United States was that the American and British educational systems are growing closer together, and that each in its own way is seeking to combine equal educational opportunity with high academic standards, particularly for specially gifted children. The three specific conclusions of the Panel relate to American conditions but are essentially valid elsewhere, particularly if it is intended to pay greater attention to specially gifted children. Moreover, as Dr. Killian emphasizes, the quality of science and of scientific education depends on the quality of the intellectual life in the society in which they are nurtured, and his plea for adequate attention to the cultivation of talent, quality and intellectual ability is one to be heeded equally in Britain.

In reaffirming his belief in the capacity of man to improve both himself and his society, Dr. Killian rejected the note of pessimism to be found in Britain as well as in the United States. He insisted that science does not contribute simply to the comfort and convenience of life: it contributes also to its quality, to the individuality from which creative work arises, to its dignity as well as to its productivity. Science, he claimed, is one of the great disciplines vital to society and worthy of first-class minds, and the growing linkage of science and technology with government demands of science a new order of poise and statesmanship, and of the scientists who serve as advisers a deep understanding of the role and limitation of the adviser. It is only when this conception of science as one of man's most powerful means for searching out truth and augmenting his dignity is fully and widely recognized that science can prosper in any country and attract its proper complement of creative and gifted minds.

It would be foolish to suggest that the new structure for bringing science and technology to play their fitting part in public policy in the United States should be slavishly imitated in Britain. The importance to Britain of Dr. Killian's review and of the report on strengthening science in the United States lies rather in indicating factors which should receive closer attention, in suggesting points of view from which our own organization may well need re-appraisal, dangers to be avoided and problems on which new and creative thinking is required. The emphasis on education is to be noted above all, for on that finally depends both the effectiveness with which science and technical advice is presented and the understanding with which it is received. Whatever criticisms may well be made as to the shortcomings of the British organization for bringing science to bear on public policy, the address which the Prime Minister gave to the Parliamentary and Scientific Committee at its annual luncheon on February 18 shows how largely this is already recognized.

Mr. Macmillan referred to the opportunities he had of listening to scientific advice, particularly in view of his departmental responsibility for the Atomic Energy Authority, and to the Government's duty to increase the scientific potential, including the provision of sufficient trained man-power through the educational system and the development of scientific and technological teaching in the schools, technical colleges and universities, as well as the provision of adequate and varied facilities for research. With his reference to the importance of international co-operation in this field, including the decision at Montreal to establish an Overseas Research Council, Mr. Macmillan's address showed that attention is already being given to the several aspects of Government support for science and technology discussed by Dr. Killian, and if the scale of that support can sometimes be challenged, the Government is at any rate aware of a responsibility. Mr. Macmillan pointed out that a Minister has, in fact, much in common with the scientist: like him, he must always be ready to study and use all known facts bearing on a problem; to search dispassionately for truth and right answers; and to be ready to recognize them when the facts force them on our understanding, whatever the cost to our previous beliefs or prejudices. No scientist could ask or expect more than that a Minister should show the courage and vision to act on such principles, or that a Government should be, as Mr. Macmillan affirmed, alert to such scientific advice, not only about what it is doing now, but also about what it might be doing five, ten or twenty years hence. Mr. Macmillan's address to the Parliamentary and Scientific Committee should encourage the scientist and technologist to examine and explore the possibilities of improving our research organization, our advisory services and our educational system; Dr. Killian's review of the work of the Science Advisory Committee may suggest with greater confidence that the task will be well worth while.

Mind and Matter

By Prof. Erwin Schrödinger. (The Tarner Lectures delivered at Trinity College, Cambridge, in October 1956.) Pp. vii+104. (Cambridge: At the University Press, 1958.) 13*s*. 6*d*. net.

A LARGE part of Prof. Heisenberg's book is entitled "Historical Sources", and consists of long quotations of great writers on physical science from Kepler to Louis de Broglie. These are selected to show the "changes in the attitude of science" that have occurred during the development of 'modern' science. Needless to say, a selection from such great thinkers made by another great thinker is in itself of profound interest. But it immediately occurs to one that we have before us some of the writings of three of the greatest contributors to the latest phase of the development; one wonders how another Heisenberg of, say, 300 years hence might quote from them in making a corresponding selection for his own time and how true an impression of this phase would be given thereby. This in turn makes one wonder what is the real significance of a selection such as Heisenberg himself has made.

The first point that seems relevant to these considerations is somewhat prosaic. Some of the contents of these books are invited addresses for various public occasions. The very care that the authors have taken to suit their particular audiences hinders them from being wholly 'professional' accounts of their subjects. Far more, one questions whether, for example, Heisenberg's first quotation from the dedication of the "Mysterium Cosmographicum" to "their Illustrious, High-born, Noble and Righteous Lords . . ." should be treated critically as the record of Kepler's scientific attitude. Again, the most fascinating parts of Prof. Schrödinger's books are his personal reflexions upon the perennial problems of the place of science in human thought; they largely transcend the particular phase of physical science to which he has contributed. Similarly, one asks if, for example, Heisenberg's quotations from W. Ostwald, who was a less inspired thinker and writer than Schrödinger, are more than his personal reflexions and if they serve to give a just indication of the contemporary trend of physical thought.

Of the dozen writers quoted by Heisenberg, probably only Galileo, Newton and de Broglie have themselves made advances in the most fundamental development of physics more important than, or as important as, those made by the three authors of the present books. Moreover, it happens that these authors have written here and elsewhere with very deep penetration about the significance of the developments to which they have contributed so much.

In passing, we may learn something from the fact that Heisenberg quotes nothing from Hamilton, Faraday, Maxwell or Rutherford, whose work contributed vastly more to the development of physics than that of the majority of writers on his list. It is that physics itself is just what it is gradually discovered to be, and physicists who are prepared to take it, literally, as they find it are able to make great progress. If it be contrary to their cast of mind to trouble much about questions of significance, that probably makes no difference to their strictly scientific work. This is almost inevitably the case, since advances come by not over-rating the significance of previous work and they have to come before their own significance can be discussed. The attitude of such physicists towards their work is akin to that of a pure mathematician in his field.

Nevertheless, for most of us it is a truism that the interest of scientific advances is in what we call their significance; and what Bohr, Heisenberg and Schrödinger are doing is to stand back from their own work in order to survey its setting in wider fields of thought and its possible influence upon such thought. Bohr's book is a collection of essays and addresses prepared over the years 1932–57, and they have all had extreme care bestowed upon them. The author says himself, "The theme . . . is the epistemological lesson which the modern development of atomic physics has given us and its relevance for analysis and synthesis in many fields of human knowledge". Heisenberg's book consists, in the first part, of a sketch of the attitude to Nature in modern physics, together with general considerations regarding intellectual problems confronting man in the situation produced by the development of his own science and technology. The second part consists of the "sources" already mentioned, which are claimed to show that modern science started with an awareness of the limitations of its scope, passed through a phase in which it forgot its own limitations, and is now appreciating these limitations with new insight. The first of Schrödinger's books is a re-issue, with one addition, of the essays previously published in "Science and the Human Temperament" (1935). His second book consists of the Tarner Lectures for 1956. It is the most far-ranging of all these books and, in one way or another, bears upon the whole range of human thought. To the reviewer it breathes a freer air than do the others. This is perhaps because Schrödinger seems less prone to regard recent developments as supremely decisive in the long roll of man's thinking and so it comes more naturally to him to look beyond them. Whereas Heisenberg says, "When we speak of the picture of nature in the exact science of our age, we do not mean a picture of nature so much as a *picture of our relationships with nature*", Schrödinger says, "The world is given to me only once, not one existing and one perceived. Subject and object are only one. The barrier between them cannot be said to have broken down as a result of recent experience in the physical sciences, for this barrier does not exist".

However, when these distinguished authors stand back to survey the whole realm of thought, it cannot be expected of the writer of a short review to stand even farther back to survey the survey. All he can do is to urge others to enjoy the extraordinary richness of thought contained in each of these brief volumes.

W. H. McCrea

ADVANCES IN MICROBIOLOGY

Annual Review of Microbiology

Vol. 12. Edited by Charles E. Clifton in association with Sidney Raffel and Mortimer P. Starr. Pp. viii + 579. (Palo Alto, Calif.: Annual Reviews, Inc., 1958.) 7 dollars.

In these days when the expanding volume of literature is the despair of every scientist who hopes to keep abreast of advance in anything more than a narrow field, the annual review volumes have become indispensable. They serve two purposes: to provide a rapid guide to recent literature and, more rarely, to present an appreciation and synthesis of recently acquired knowledge. The latter type of review article is only possible when knowledge in a particular branch has reached a degree of attainment and significance that enables something more than appraisal of detail to be attempted. Three of the major articles in the present "Annual Review of Microbiology" are in this latter class and each makes a valuable contribution in its own right: "Metabolism of Carbohydrates and Related Compounds" by S. R. Elsden and J. L. Peel is an outstanding contribution, particularly in its consideration of the energetics of anaerobic metabolism, discussing the breakdown of substrates from the point of view of the yield of adenosine triphosphate. The article also covers cellulose synthesis and breakdown, the breakdown of aromatic compounds, and tricarboxylic acid cycles. "Bacterial Genetics" by A. W. Ravin reviews advances on the mutation, replication, transfer and function of genetic material, and the contribution by A. Nason and H. Takahashi places recent studies on denitrification, nitrate utilization, nitrification and nitrogen fixation into perspective in the field of "Inorganic Nitrogen Metabolism".

"Bacterial Protoplasts" and "Bacterial Viruses" are dealt with by C. Weibull and W. Weidel, respectively, while L. Provasoli presents a thoughtful study of the relation between laboratory and field investigations in the "Nutrition and Ecology of Protozoa and Algae". The parasitic and pathogenicity aspects of microbiology are well catered for in this volume, which contains reviews on staphylococci, respiratory tract viruses, virus infection in plants, parasitic diseases in man, and the use of bacteria grown *in vivo* for studies on the basis of their pathogenicity. The control of infection is discussed in articles on antibiotics in plant disease, chemical disinfectants, and radiation preservation of food. P. Grabar provides a further summary, with 200 references, of recent Russian literature.

It can be seen that the present volume, containing nineteen articles and a grand total of 3,211 references, will find a place on the shelves of microbiologists, medical men and biochemists, all of whom will acknowledge their indebtedness to the editors and contributors for maintaining the high standard that we have come to expect of these "Annual Reviews".

TOPICS IN CARBOHYDRATE CHEMISTRY

Polysaccharides in Biology

Transactions of the Second Conference, April 25, 26 and 27, 1956, Princeton, N.J. Edited by Dr. George F. Springer. Pp. 245. (New York: Josiah Macy, Jr. Foundation, 1957.) 5 dollars.

This book gives a verbatim account of the transactions of a second conference, sponsored by the Josiah Macy, Jr. Foundation. It brought together a group of experts who discussed three topics in carbohydrate chemistry, namely: "Sialic Acid and Related Compounds"; "Interaction of Polysaccharides and Viruses"; and "Pyrogens". These topics are of the utmost importance in certain aspects of medicine at the present time, and the twenty-six experts were undoubtedly among the best that could be got together for the particular subjects. The method of reporting the conference, however, must be sharply criticized, because it can only be of value to the expert: even to the expert it is very irritating, but to the non-specialist it would be almost impossible to get anything of real significance out of the book. The whole thing is reported in a completely uncritical manner, and many comments of the experts, some of them mere interjections, are of no value. Perhaps the scientific editors will in future take a leaf out of the books of the Ciba Foundation and provide a substantial piece of well-thought-out writing on which to base the main conclusions of a topic: then comments by participants in the succeeding discussion will have more weight and will be more tangible.

The discussion on sialic acid and related compounds was led by Dr. F. Zilliken, and generally all that is known about this interesting group of substances up to 1956 was brought out either by direct communication or by discussion. The growing importance of this nonosaminic acid was well illustrated by the experiences of the participants in a number of fields.

The discussion of polysaccharides and viruses was led by Frank L. Horsfall, who was allowed to make at least a page and a half of contribution before he was interrupted by his fellows. It did emerge that the twenty or more viruses react in one way or another with erythrocytes. Many of them can cause hæmagglutination, a phenomenon which can be inhibited specifically by complex polysaccharides of the muco-protein class. Powerful inhibitors of viral hæmagglutination may be found in urine, egg-white, serum, and so on. The animal viruses may be divided into three groups: those which contain particles which react with the red cells, are absorbed, and then emerge again; others which contain components which react and are absorbed by the red cell but cannot be released; and the third group which does not attach itself to a red cell but produces a soluble substance that does attack the cell.

The discussions on the implications of these new interactions of polysaccharides and viruses components are intensely interesting. The discussion on pyrogens was led by Dr. O. Westphal, of the Wander Research Institute, Freiburg, Germany. Pyrogens are substances which, after injection in higher animals, promote a rise in body temperature. Among these are many polysaccharides, particularly those which are elaborated by bacteria. The problem of pyrogen production is, of course, of the greatest importance in medical treatment. Those discussed were of the lipo–polysaccharide–protein complex type. In this discussion masses of observations by the different participants were described and in one way or another almost all the constituents of Gram-negative bacteria have been brought in. The nature of the properdin system and its reaction with polysaccharides were well discussed and comparisons were made between properdin and antibody. In some cases these are well described in tables and diagrams, but they are very difficult to sort out in regard to their relative importance.

Excellent references are given, and to the expert, the whole of this discussion will be of the greatest value and interest. However, to make the book of wider appeal and the discussions of greater value in the future, it is to be hoped that the editor will make a critical assessment of those positive results which have emerged from discussion.

M. Stacey

POPULATION ECOLOGY

Animal Ecology To-Day

By Prof. F. S. Bodenheimer. (Monographiae Biologicae, Vol. 6.) Pp. 276. (Den Haag: Uitgeverij Dr. W. Junk, 1958.) n.p.

Cold Spring Harbor Symposia on Quantitative Biology

Vol. XXII: Population Studies—Animal Ecology and Demography. Pp. xiv+437. (Cold Spring Harbor, L.I.: Long Island Biological Association, 1957.) 8 dollars.

Bodenheimer's "Problems of Animal Ecology" (1938) has for some time been out of print. Although broader in scope, "Animal Ecology To-Day" is essentially a revision of the earlier book in the light of twenty years added experience. The central theme remains that "the principal aim of ecological research is to explore the fluctuation of populations and their (homologous) causes". From this point of view Bodenheimer discusses longevity (Chapter 1), life-history (2), population dynamics (3 and 4), the community (5), environment and heredity (6) in animals, and ends with a brief dissertation on human ecology (7). Many of the illustrations are from works unfamiliar to Western readers. As might be expected in a widely ranging treatise, a few subsections are not quite up to date.

"Animal Ecology To-Day" is truly, as the author says, "not written against anyone or against any theory" quoted or discussed. Nevertheless, it is still to a considerable extent a fairly strong testament of Bodenheimer's personal views. Naturally, he has changed some of the latter since 1938; for example, on the question of weather in population dynamics. At the same time, he is sometimes penetratingly critical of opposing views, as when he points out that parasites can be wrongly credited with controlling increase of their hosts (Fig. 17). This is not a book for beginners. It should be regarded as a thought-provoking supplement to text-books such as those of Allee *et al.* and Andrewartha and Birch. The mature ecologist will find much with which to agree and much with which to disagree. Where acceptable it is sometimes illuminating, and where unacceptable it is occasionally stimulating. Theorists, and those who do not readily distinguish between theory and fact, should profit by reading pp. 190–201.

For up-to-date comprehensive surveys, biologists the world over owe much to the organizers of the carefully edited and beautifully produced "Cold Spring Harbor Symposia". Vol. 22, on population studies, puts them still further in debt. No serious worker on population problems can afford to be without access to it. Containing thirty-six papers (with useful discussions of twenty-four), it is devoted about equally to human and animal populations. Many of the authors are well-known authorities in their subjects and about one-third are from outside the North American continent. Representation is well balanced with respect to controversial matters; for example, the question of natural control of animal populations. Beginning with a very capable introductory survey (containing, as seems to be inevitable, its author's own views at some length), the volume effectively covers most of the important aspects of population study—historical, theoretical, laboratory and field. One is still waiting, however, for geneticists to direct their attention from evolution to regulation of populations. Like all symposia (cp. "The Numbers of Man and Animals"), this volume has disjointed and ill-assorted features. One therefore admires the realism of the author of the "Conclusion", who soon abandons all pretence of summing up the proceedings and devotes most of his paper to expounding a particular view of his own. After all, no one could be expected to sum up proceedings on two subjects so different (despite some basic similarities) as human and animal populations, and including papers on aspects as diverse as "Farris' Formula for predicting Fertile Days" in women and "Roosting Habits, Sexual Dominance and Survival in the Great Tit". Future symposia should be on either human or animal populations, but not on both.

In animal ecology to-day there is less need for new books than for an international committee to define and standardize terms and concepts. Perusal of these two volumes makes this abundantly clear.

A. Milne

Hemophilia and Hemophilioid Diseases

International Symposium. Edited by Prof. Kenneth M. Brinkhous. Pp. xxii+265. (Chapel Hill, N.C.: University of North Carolina Press; London: Oxford University Press, 1957.) 60*s*. net.

In August 1956 a symposium, sponsored by the National Hemophilia Foundation of the United States, was held in New York. About 125 persons attended, and among the 62 who read papers or contributed to the discussion were included a high proportion of the scientists and clinicians of the present day who have contributed most to the study of hæmophilia and allied disorders. The present book is a record of this meeting, consisting of 29 papers divided into seven main sections and verbatim reports on subsequent discussions. Most of the papers are illustrated by figures and most of them include adequate lists of references.

The papers are inevitably of uneven quality; some are short general summaries, others describe experiments in detail. One of the most interesting and controversial subjects discussed inconclusively at the symposium was the frequency with which anticoagulants or inhibitors are found in the plasma of hæmophiliacs and their importance in the pathogenesis of bleeding. The discussion at the end of each group of papers makes interesting reading, even if the questions asked and statements made often pose more questions than they answer.

A good example of a tantalizing statement is to be found at the foot of p. 62. In it R. J. Carroll states that hæmophiliacs are graded 1, 2, 3 and 4 on the basis of the anticoagulant content of their plasma and that the grade is constant for a particular patient. It need perhaps scarcely be added that there is still no uniformity of opinion as to whether anticoagulants really exist in hæmophilic plasma except on rare occasions.

This is a book for those who have a special interest in the hæmorrhagic disorders, whether they be physicians, clinical pathologists or medical scientists. It does not seem likely to have much appeal to workers outside this field.

J. V. Dacie

Biological Aspects of the Transmission of Disease

Edited by C. Horton-Smith. (Reports of Symposia of the Institute of Biology.) Pp. ix+184. (Edinburgh and London: Oliver and Boyd, Ltd., 1957. Published for the Institute of Biology.) 21*s*. net.

"Biological Aspects of the Transmission of Disease" is the title of the proceedings of symposia organized by the Institute of Biology. It covers such a wide range of subjects that few reviewers would feel competent to do it justice. With the increasing specialization in all aspects of biology, it is very refreshing and most instructive to read accounts of problems of transmission of disease in fields or media totally different from those known to the reader.

As is inevitable in asking experts to write briefly on very complex subjects, one can find minor errors and ambiguity in places, but this does not really detract from the value of this kind of book in widening the field of interest and, one hopes, whetting the appetite of the reader to pursue further many original papers by the eminent contributors.

Unfortunately, it is a small book for a guinea.

C. W. Dixon

The Astronomer's Universe

By Prof. Bart J. Bok. Pp. xi+107+16 plates. (Melbourne: University of Melbourne Press; London: Cambridge University Press, 1958.) 21*s*. net.

The author of this book, who was formerly on the staff of the Harvard Observatory, is now director of the Commonwealth Observatory and professor of astronomy in the Australian National Observatory. The book is based on four lectures delivered in Canberra, in which some account was given of the more important developments that have been made in recent years in our knowledge of the universe. The first of these lectures deals with some problems of the solar system, including the atmospheres of the planets, the origin of the system, and the Sun's corona. The second is concerned with some of the properties of stars as individuals and describes the two types of stellar populations found, respectively, in the spiral arms of galaxies, and in stellar clusters and galactic nuclei. The third lecture is concerned with the Milky Way system and summarizes the evidence for the existence of spiral arms from optical and radio observations. The final lecture is somewhat more speculative in character, discussing matters, such as the cosmic time-scale, stellar evolution, and the birth of stars, on which much evidence has been obtained in the past decade.

The book avoids technicalities and is well written. It will interest all who wish to know how astronomical ideas are tending in many important problems which still await definite solutions. The book, which was printed in Melbourne, is well produced and has reproductions of a number of stellar photographs, several of which were obtained at the Commonwealth Observatory.

H. Spencer Jones

Physical Acoustics and the Properties of Solids

By Dr. Warren P. Mason. (The Bell Telephone Laboratories Series.) Pp. xii+402. (Princeton, N.J.: D. Van Nostrand Company, Inc.; London: D. Van Nostrand Company, Ltd., 1958.) 67*s*. 6*d*.

Workers in acoustics look forward eagerly to a new book from the pen of Dr. W. P. Mason, who brings to his writings the authority and experience of many years on the research staff of the Bell Telephone Laboratories. As head of mechanics research he is writing of his own work and that of his associates in the main, though with frequent comparison of the Bell methods with those of other laboratories. The title of the book is possibly a little misleading since the words "physical acoustics" are evidently to be taken in conjunction with the words that follow—the introduction gives, in fact, the basic theory only in reference to the propagation of sound waves in solids.

The experimental portion covers in four chapters the sources (mostly ultrasonic) which can be used for transmitting longitudinal or shear waves in bars, the method of determining the velocity and attenuation of the signals launched into them, together with industrial applications of these experiments, like the ultrasonic flaw detector and the soldering iron, for which British firms have gained credit.

Part 2 of the book will have most appeal to physicists, since it discusses the theory of transmission of these waves in terms of dislocations, grain boundary losses, and lattice vibrations with their relaxations. The general reader can, in fact, appreciate from this authoritative account the important part which acoustics is playing to-day in solid state physics.

E. G. Richardson

SOCIAL IMPLICATIONS OF MENDELISM VERSUS MICHURINISM

By A. QUINTANILHA

Centro de Investigação Científica Algodoeira, Lourenço Marques, Mozambique

THE rediscovery of Mendel's Laws in 1900 raised the greatest interest in the world of science. Such a great amount of knowledge on the behaviour of the chromosomes, in the somatic life as well as in the sexual reproduction of plants and animals, accumulated during the last twenty years of the nineteenth century that it was not difficult to find a perfect parallel between this behaviour, on one hand, and the transmission of hereditary units, on the other. Thus was born the chromosome theory of heredity, an eminently materialistic theory which tried to localize in material particles, along the chromosomes, the factors responsible for the transmission of those hereditary characters which follow Mendel's Laws.

However, the fact that the first Mendelian geneticists were essentially interested in the problem of transmission of hereditary characters, that is, in the phenomenon of permanence, throughout the generations, of characters already existent in the ancestors, caused a great number of biologists and a considerable part of public opinion to suspect that the geneticists of the then new school were anti-evolutionists and reactionaries. This suspicion was reinforced by the fact that Mendel was a Catholic priest; and, on the other hand, by the circumstance that the Mendelian geneticists did not accept the Lamarckian theory of the heredity of acquired characters.

But after the first years of confusion the situation became clearer. The new school of Mendelian genetics accepted, as a demonstrated fact, the doctrine of evolution; and, as all the experiments trying to demonstrate the heredity of acquired characters led to negative results, they looked for the explanation of evolution in spontaneous mutability and natural selection.

In 1935, Lysenko started a campaign, partly scientific and partly political, against Mendelian genetics. Using, and, in my view, abusing, the name of Michurin, who enjoyed great popular prestige in the U.S.S.R., Lysenko tried to create a new school of Soviet biology of a strong nationalistic and anti-Mendelian tendency.

Mendel's fundamental and most original idea is that there are independent units of heredity responsible for the transmission of those characters which follow mathematical laws. The followers of Mendel succeeded in demonstrating that such units really exist, and are material particles localized in the chromosomes.

The Michurinists, on the contrary, deny the existence of cellular organs responsible for the transmission of hereditary characters. Heredity, they say, is a function of the organism as a whole, and not of any one specific organ. In grafting, for example, the scion as well as the stock can transmit to one another hereditary characters by means of plastic substances. "The plastic substances", wrote Lysenko, "produced by the scion and the stock, possess the characters of the breed, are endowed with definite heredity just as the chromosomes, and just as any particle of the living body"[1].

The Michurinist theory seems to me, on this point, in complete disagreement with the coherent results of half a century of cytogenetic research. To deny the specific role of the chromosomes in transmission of those hereditary characters which obey Mendel's Laws would be as absurd as to deny the specific role of the chloroplasts in carbon assimilation in green plants.

But the most interesting aspect of the question is that Michurin himself was not a Michurinist in the same sense as Lysenko. He himself confesses: "Unfortunately, I at first was enthusiastic about Grell's ideas of those days concerning the acclimatization of the best foreign varieties by grafting them on to hardy wild plants. Much labour and time were lost on these erroneous experiments before I finally became convinced that the method was useless. Then, following the advice of Dr. Betling, I began to breed my own new local varieties of fruit-bearing plants from the seeds of superior quality fruits. But it soon became clear to me that I could not expect to accomplish much without artificially crossing local varieties of plants with the best foreign varieties, because it is difficult to obtain higher qualities from mediocre varieties. To achieve this, the fruit of one of the parent plants must possess better, outstanding qualities. Consequently, it was necessary to resort to hybridization"[2].

That is, while Michurin used the Lamarckian methods of progressive acclimatization of varieties from temperate climates to the hard conditions of central Russia, he had only failures. Then he started working as any plant breeder of the Mendelian school would, that is, crossing varieties highly resistant to cold with others from temperate climates, not resistant but producing fruits of outstanding quality, and selecting among the descendants those plants bearing a new and desirable association of characters. Michurin was then acting as if he accepted the Mendelian principle of the existence of independent hereditary units susceptible of being associated in new combinations. He was carrying out Mendelian plant breeding.

Moreover, the impression which one gets from reading Michurin's "Selected Works" and from his biography is that he was a modest man without any kind of pretension to create a new biological doctrine and without the aggressiveness characteristic of the writings of his disciple and admirer, Lysenko. His criticism of the Mendelian theories is, above all, the consequence of a deficient scientific education. As a self-taught man, Michurin must have met with enormous difficulties in access to works of reference, and it is highly probable that he never read Mendel's original work.

In an article published in 1925, in which he gives a summary of the results of half a century's work, he says: "In conclusion, I should like to note that in general, and in the brief résumé of my work in particular, I make no pretensions of having demonstrated new discoveries or having refuted any laws established by authorities in science.

"It is very probable that in some cases I may be wrong due to having erroneously interpreted various phenomena in the life of plants and the application of, let us say, the laws of Mendel or other modern teachings to them; but such mistakes are inevitable in every work and they cannot be of much significance since they will in all probability be rectified by other investigators in the future"[3].

It is strange to notice that the Michurinists accept enthusiastically and with great praise Darwin's materialistic theory of evolution with the exception of its most original part, the principle of natural selection, as a consequence of the struggle for life, and the survival of the best adapted. Yet, strange though this may seem, it can be explained. Darwin himself confesses: "In October 1838, that is fifteen months after I had begun my systematic inquiry, I happened to read for amusement *Malthus on Population*, and, being well prepared to appreciate the struggle for existence which everywhere goes on from long continued observation of the habits of animals and plants, it at once struck me that under these circumstances favourable variations would tend to be preserved, and unfavourable ones to be destroyed . . . Here then I had at last got a theory by which to work"[4].

Now the work of Malthus was published for the first time in 1798 in an atmosphere of controversy. Against the socialist doctrine that misery is a consequence of a faulty social organization, Malthus tried to prove that, on the contrary, misery was the necessary consequence of a natural law, the law which rules the growth of population. When there are no obstacles, the human population, like those of other animals, tends to grow in geometric progression, while the means of subsistence grow in arithmetic progression.

Misery in the last analysis is the unavoidable consequence of this disproportion, of this 'natural law'. Great famines, wars, epidemics, social or natural cataclysms are so many other means which re-establish automatically a certain equilibrium between the number of mouths and the possibility of feeding them.

Social reforms, raising the standard of living of the poorer classes, far from solving the fundamental problem, may even help to aggravate the situation; as a matter of fact, stimulating the birth-rate of the working classes by a temporary increase in their well-being may create in this way a greater future discrepancy between the population and the means of subsistence.

For Malthus the problem is not a social one, and it is not possible to solve it by re-organizing human society on different bases. The only solution would be the exercise of 'moral restraint'—abstention from marriage for poor people who could not feed and educate their families, and the practice of conjugal continence for married people in similar conditions.

The application of Malthusian principles to animals and plants allowed Darwin to find an explanation of evolution, that is, the appearance of new species derived from pre-existent ones. An unavoidable consequence of the population law is the struggle for life, for breathing space and means of subsistence between individuals of the same species. As soon as the species covers a sufficiently large area, in each place there will be greater probability of survival for individuals bearing variations which make them better adapted to the local conditions. From this arises the tendency for the formation, inside the species and in different ecological areas, of nuclei of populations with different hereditary characters, each of which is the possible starting point for the formation of a new species.

During the nineteenth century, economists and sociologists tried to use Malthus's doctrine against socialist propaganda. In the same way Darwin's theory of the struggle for life and the survival of the fittest was used to justify the existence of human societies divided into classes with different functions and different rights.

Competition, the struggle for life among individuals of the same species, would be in this way a natural law from which human society could not escape. Just as in other animal societies, the struggle for life among human beings would lead to the success of the fittest. It would then be quite in order to give the upper classes functions of direction. Misery, hunger, unemployment are not only unavoidable consequences of biological laws; but in their way they contribute to the slowing-down of procreation in the worst-adapted classes of society.

It is not difficult to understand the violence of the reaction in socialist circles, not only against Malthus's doctrine on population, but also against the political-social consequences which sociologists pretended to deduce from Malthus's and Darwin's doctrines.

Karl Marx, in his famous book "Das Kapital", attacked Malthus sharply and asserted that an abstract law of population can only exist for plants and animals. In human societies a particular law of population corresponds to each type of social organization of production. In the capitalist society of the nineteenth century, the limiting factor in population increase was the possibility of obtaining work. The working classes were permanently under the menace of unemployment crises, an unavoidable consequence of a social organization which produced not for consumption but for sale.

Engels's reaction was not less violent, and extended to the consequences which, in reactionary circles, they pretended to deduce from Darwin's doctrines. In a letter published in 1875 he wrote: "The entire Darwinian teaching on the struggle for existence merely transfers from society to the realm of living nature Hobbes' teaching on *bellum omnium contra omnes* and the bourgeois economic teaching on competition, along with Malthus' population theory. After this trick (the absolute justification for which, as indicated in point 1, I deny, particularly in regard to Malthus' theory) has been performed, the same theories are transferred back from organic nature to history and the claim is then made that it has been proved that they have the force of eternal laws of human society. The childishness of this procedure is obvious, and it is not worth while wasting words on it. But if I were to dwell on this at greater length, I should have started out by showing that they are poor economists first, and only then that they are poor naturalists and philosophers"[5].

Kautsky accepted the Malthusian principle that human populations, like animal ones, *tend* to grow quicker than the amount of available food. But, like Marx, he directed attention to the circumstances that, in capitalist societies, what limits the production is the antagonism of interests between the proprietors and the workers. Once this antagonism disappears through the advent of socialism, the production of means of subsistence will be able to increase in unprecedented proportions. But, according to Kautsky, this will not yet solve the problem, because the tendency of a more rapid increase in population than in the means of subsistence will remain. The solution, however, is not in the abstention from marriage nor in the practice of continence, as Malthus preached, but in a future birth-control. Already in 1880 Kautsky foresaw that birth-control would be more and more used as the cultural level of human society rose.

The solution of the tragic problem posed by Malthus at the end of the eighteenth century is then, for Kautsky, in the advent of socialism and in the practice of birth-control.

Another great socialist who wrote widely about the problem was Kropotkin. In his book "Mutual Aid as a Factor of Evolution", Kropotkin tried to demonstrate that, besides the struggle for life among individuals of the same species, another factor of evolution exists, namely, mutual aid. In animal populations, as soon as social life becomes intensified, there develops a spirit of co-operation and solidarity. The struggle of one against all for the means of subsistence tends to be little by little replaced by the struggle of all the individuals of the same society against their common enemies and against adverse natural conditions.

As soon as animals start to live in societies a new factor intervenes in natural selection, namely, the instinct of sociability (gregariousness). Within each species Nature will select those individuals in which this instinct is most highly developed. In inter-specific competition, those species in which social life is best organized will have greater chances of success.

Many other socialist leaders took an active part in the controversy which arose around the thesis put forward by Malthus and the social consequences which many sociologists pretended to take from his doctrines and from that part of Darwin's theory of Malthusian origin.

Now we can understand better the attitude of the Michurinists who, imbued with an out-of-date Marxism, were never able to understand that the admission of the existence of a struggle for life between individuals of the same species, in the plant and animal kingdoms, does not in any way justify the social consequences which the opponents of socialism pretend to deduce against the socialist doctrine.

In the plant kingdom and in a great number of animal species the struggle for life, even among individuals of the same species, is a biological fact so evident that it seems to me difficult to deny it. But already in many animal species, as soon as a social life starts, this struggle begins to be gradually replaced by co-operation between the members of the same community against their external enemies and the adverse conditions of Nature: and who would be better placed than the Russian biologists to assert that, in human societies, it is possible and advantageous to replace the principle of competition between individuals of the same community by the principles of co-operation and mutual aid?

Modern history proved the correctness of the socialist leaders' predictions in the Malthusian controversy. In modern human societies the reproduction-rate decreases, in spite of the spectacular decrease in mortality, with the increase in their cultural level. Deliberate birth-control tends, therefore, to establish an automatic balance between the number of mouths to be fed and the possibility of feeding them. On the other hand, the advent of socialism and consequent disappearance of antagonistic class interests has shown the possibility of developing agricultural and industrial production, even in backward countries, in a way without precedent in human history.

The rejection by the Michurinists of the Darwinian doctrine of the struggle for life as a factor of evolution is, in my opinion, the consequence of a social–political prejudice, the erroneous conviction of the incompatibility between that doctrine and the socialist ideal of a classless society based on the principle of co-operation.

DENSITY OF THE ATMOSPHERE AT HEIGHTS BETWEEN 200 KM. AND 400 KM., FROM ANALYSIS OF ARTIFICIAL SATELLITE ORBITS

By D. G. KING-HELE
Royal Aircraft Establishment, Farnborough

THE action of atmospheric drag makes the orbit of an Earth satellite slowly contract, and its period of revolution T decrease. When the eccentricity of the orbit exceeds about 0·02, the drag at perigee is much greater than at apogee, and the rate of decrease of T is determined by the total loss in velocity due to the integrated effect of drag in the region near perigee. If the mass and dimensions of the satellite are known, and estimates are made of its aerodynamic drag, values of air density at heights near perigee can be obtained.

Such estimates of air density have been made in a number of previous papers[1–11]. Since the effective cross-sectional areas and drag coefficients of the satellites are difficult to determine exactly, the various authors have inevitably made different estimates of these quantities. Also most of the previous papers refer to only one or two satellites. In the present article, values of density are derived from all the ten satellites launched up to the end of 1958 whose orbits are known, the satellites are treated consistently, and a more accurate method of determining density is used.

Previous Estimates

The results from the previous papers[1–11], and values[12] obtained from instruments aboard *Sputnik* 3 (1958 δ 2), are collected in Fig. 1, together with two proposed interim model atmospheres[3,13] and the A.R.D.C. model atmosphere[14], which was probably the most widely used standard atmosphere in the year prior to satellite launchings. As is well known, the results from satellites show the density in the

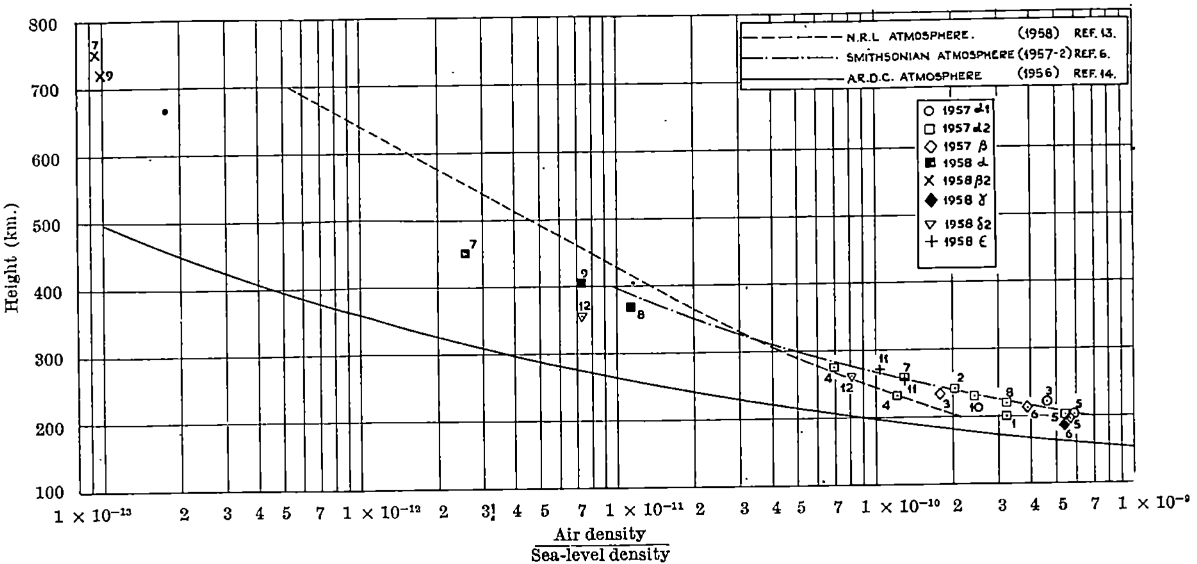

Fig. 1. Values of air density obtained by means of satellites (refs. 1–12), with proposed 'standard atmospheres' (refs. 6, 13, 14). Reference numbers are shown beside the plotted points

200–400 km. height range to be 5–15 times greater than indicated by the A.R.D.C. model. In Fig. 1, the abscissa is the density relative to sea level, the sea-level density being taken as 1·23 kgm./m.^{3} or 0·0765 lb./cu. ft. The scatter of the points in Fig. 1 is not significant, since it could be due to the different methods and assumptions of the different investigators.

Present Method of Analysis

It is customary to express the air drag D encountered by a body moving with velocity v in air of density ρ in terms of a drag coefficient C_D as:

$$D = \tfrac{1}{2}\rho v^2 S C_D \qquad (1)$$

where S is a reference area, which may here be taken as the mean cross-section of the satellite perpendicular to the direction of motion. If a satellite of mass m is in an orbit with semi-major axis a and eccentricity e between 0·015 and 0·15, the air density at perigee, ρ_p, can be expressed[5,15] as:

$$\rho_p = -\frac{dT}{dt}\,\frac{m}{3\,SC_D}\sqrt{\frac{2e}{\pi a H}}\left\{1 - 2e - \frac{H}{8ae} + 0\left(e^2, \frac{H^2}{a^2e^2}\right)\right\} \qquad (2)$$

where dT/dt is the rate of change of the period of revolution T, which can be determined accurately from observation. In deriving equation 2, it is assumed that, above perigee height y_p, the density of the air varies exponentially with height, the density ρ at height y ($> y_p$) being given by:

$$\rho = \rho_p \exp\left\{-\frac{y - y_p}{H}\right\} \qquad (3)$$

where H is constant. Since the value of H is not accurately known at heights of 200–400 km., equation 2, though it determines $\rho_p\sqrt{H}$ with little error, does not yield an accurate value of ρ_p.

This limitation can, however, be avoided. Let H^* be the best estimate of H. Then the density at height $y_p + 0{\cdot}5H^*$ may, by means of equations 3 and 2, be expressed as:

$$\rho_{p+0\cdot5H^*} = \rho_p \exp\left(-\frac{H^*}{2H}\right)$$
$$= -\frac{dT}{dt}\,\frac{m}{3\,SC_D}\sqrt{\frac{2e}{\pi a H^*}}\left[\sqrt{\frac{H^*}{H}}\exp\left(-\frac{H^*}{2H}\right)\right]\left\{1 - 2e - \frac{H^*}{8ae} + 0\left(e^2, \frac{H^2}{a^2e^2}\right)\right\} \qquad (4)$$

The function in square brackets is insensitive to the value of H^*/H, and may be taken as 0·593, with error less than 2·5 per cent, if the estimated value H^* does not differ from the true value H by a factor of more than 1·5. Since H is usually known to within a factor of 1·5, and since the likely error in m/SC_D is as a rule appreciably greater than 2·5 per cent, it is legitimate to replace the term in square brackets in equation 4 by this constant, so that (4) becomes:

$$\rho_{p+0\cdot5H^*} = -\frac{0{\cdot}158\,m}{SC_D}\,\frac{dT}{dt}\sqrt{\frac{e}{aH^*}}\left\{1 - 2e - \frac{H^*}{8ae} + 0\left(e^2, \frac{H^2}{a^2e^2}\right)\right\} \qquad (5)$$

The error arising from neglect of terms in e^2 and H^2/a^2e^2 is less than 3·5 per cent if $0{\cdot}015 < e < 0{\cdot}15$. The use of equation 5 to obtain the density at height $0{\cdot}5H^*$ above perigee should not lead to errors of more than 4·5 per cent if H^* is not in error by a factor of more than 1·5. If H^* is in error by a factor of 2, the error in equation 5 rises to 12 per cent.

Evaluation of m/SC_D

In applying equation 5 to actual satellites, the chief difficulty is the evaluation of SC_D. Its value depends on the shape of the satellite, the manner in which it is rotating, and the mechanism of reflexion of the air molecules. Diffuse reflexion, in which the air molecules are re-emitted in a random manner after striking the surface, has been chosen as the most likely mechanism, in preference to specular reflexion, in which the molecules are reflected as if from a mirror. Though there is scope for argument about the speed of re-emission of the molecules in diffuse reflexion, the drag coefficients obtained under the various possible assumptions do not differ by more than about

Table 1. Values of Mass m and m/SC_D for Satellites 1957 α–1958 ζ

Satellite		Mass, m (kgm.)	m/SC_D (kgm./m.^{2})
Sputnik 1	1957 α 2	83	110
Sputnik 1 rocket	1957 α 1	—	62
Sputnik 2	1957 β	—	58
Explorer 1	1958 α	14	23
Vanguard 1	1958 β 2	1·5	23
Explorer 3	1958 γ	14	23
Sputnik 3	1958 δ 2	1,327	190
Sputnik 3 rocket	1958 δ 1	—	59
Explorer 4	1958 ε	17·5	29
Atlas	1958 ζ	3,960	28

5 per cent. It has been assumed here that the re-emission speed has a Maxwellian distribution about the speed appropriate to the temperature of the satellite, and drag from electrical forces has been ignored.

The value of SC_D is most difficult to estimate for the nearly cylindrical satellites, *Explorers* 1, 3 and 4 and *Atlas* (1958 α, γ, ε and ζ). It appears very probable, both on general dynamical principles and from observations[7], that each of these cylindrical satellites, and the rockets of the Russian satellites[10], have rotated about their axis of maximum moment of inertia, that is, an axis perpendicular to their length, though the angle between this axis of rotation and the direction of motion has varied. If this picture is correct, the two extreme modes of rotation are (*a*) travelling exactly like an aeroplane propeller, and (*b*) tumbling end-over-end. In (*a*), the axis of spin and the direction of motion are parallel; in (*b*), they are at right angles ; and in practice the angle may be anywhere between these extremes. A recent study (G. E. Cook, unpublished work) has shown that, under the assumption of diffuse reflexion, a rotating cylinder of length l and diameter d ($d \sim 0{\cdot}1\, l$) has a value of SC_D of about $2{\cdot}2\, ld$ under regime (*a*) and about $1{\cdot}5\, ld$ under regime (*b*). For any motion between these extremes, SC_D lies between $1{\cdot}5\, ld$ and $2{\cdot}2\, ld$. The nearly cylindrical satellites have been treated here as cylinders, with SC_D taken as $1{\cdot}85\, ld$, the mean of the values under regimes (*a*) and (*b*). If each satellite has rotated about its axis of maximum moment of inertia, this value of SC_D will not be in error by more than 19 per cent.

The spherical satellites *Sputnik* 1 and *Vanguard* 1 (1957 α 2 and 1958 β 2) both have cylindrical antennæ, and their drag coefficient C_D has been taken as 2·2, with S as the mean cross-section during one rotation. This value should not be in error by more than 5 per cent, since $C_D \simeq 2{\cdot}1$ for a sphere and $C_D \simeq 2{\cdot}2$ for a rotating cylinder. For the conical *Sputnik* 3 (1958 δ 2), S has been taken as the mean of the cross-sections in modes of rotation (*a*) and (*b*), with $C_D = 2{\cdot}3$. For *Sputnik* 2 (1957 β), no weights and dimensions are available, but the value of m/SC_D can be inferred from *Sputnik* 1. Since the perigee heights of *Sputniks* 1 and 2 were virtually the same[10], equation (2) gives :

$$\left(\frac{m}{SC_D}\right)_2 = \left(\frac{m}{SC_D}\right)_1 \sqrt{\frac{a_2 e_1}{a_1 e_2}} \left(\frac{dT}{dt}\right)_1 \Big/ \left(\frac{dT}{dt}\right)_2 \qquad (6)$$

where suffixes 1 and 2 refer to *Sputniks* 1 and 2, respectively. Since the factors on the right-hand side of (6) are known, $(m/SC_D)_2$ can be found. Values of m/SC_D for the rockets of *Sputniks* 1 and 3 (1957 α 1 and 1958 δ 1) can be found similarly. This indirect method should be reliable if, as is believed[16,17], each of the satellites 1957 α 1, 1957 β and 1958 δ 1 retained a virtually constant value of m/SC_D until the last day of its life.

The values of m/SC_D obtained by these various methods for the satellites with known orbits launched in 1957 and 1958 are listed in Table 1. If the assumptions already stated are justified, the error (standard deviation) in the tabulated values of m/SC_D will probably be about 10 per cent.

Evaluation of Air Density

If values of m/SC_D are available, the air density at height $0{\cdot}5H^*$ above perigee can be found from equation 5. For the Russian satellites, values of dT/dt, a and e have been taken from orbital determinations made in Britain[2,18–20]. For the American satellites, values have been obtained from the orbital data regularly issued as part of their prediction services by the Smithsonian Astrophysical Observatory, Cambridge, Mass., and Project Space Track, Bedford, Mass. The values of H^* chosen are consistent with values of H given later in this article.

The resulting values of density, from all the satellites in Table 1, are plotted in Fig. 2, and a curve has been drawn through the points to indicate likely average values for density. It is usual when constructing a 'model atmosphere' to make a plausible assumption about the variation of temperature and air composition with height, and thence derive density. Since the primary measurements are of density, however, it seems more logical to take the density as the basic parameter and then to deduce temperature from it. This procedure has the further merit that it shows the large errors in temperature which can arise, even when a good fit is achieved for the density.

Several features of Fig. 2 are worth noting :

(1) The ten different satellites give surprisingly consistent values of air density. None of the 15 plotted points in the cluster between 190 km. and 260 km. differs from the curve by a factor greater than 1·4, and the average factor of difference is about 1·2. Probably, therefore, the assumptions made were not grossly in error, as they would have been if, for example, one of the cylindrical satellites had flown like an arrow instead of rotating.

(2) Even if the method of analysis were perfectly accurate, the points in Fig. 2 would not all lie on the same curve, since the effective air density is known to vary from day to day and month to month, by up to 30 per cent at 200–250 km. height[16,17] and by a factor of 3 at 700 km. (ref. 21). The curve in Fig. 2 can therefore only represent average values.

(3) The points in Fig. 2 cover latitudes between 50° N. and 35° S. ; but there is no sign of any regular variation with latitude, and the spread of the points suggests that, between 50° N. and 35° S., density does not depart from its average value by a factor of more than about 1·5. This is in contrast with results from rocket experiments[22], which suggest a variation by a factor of up to 5 between 59° N. and 33° N. on a summer day. The accuracy of initial estimates of life-time for the Russian satellites, the perigees of which moved from an initial latitude near 50° N towards the equator, also suggests that density does not vary greatly within this range of latitude.

(4) The one point above 400 km. in Fig. 2 should not be taken seriously, partly because it is unsupported and partly because the effect of charged drag[23] is likely to be important at 700 km., where more than 5 per cent of the atoms may be ionized.

Table 2 lists values of average density from the curve in Fig. 2, for heights between 200 and 400 km., where the error-factor should not exceed 1·5.

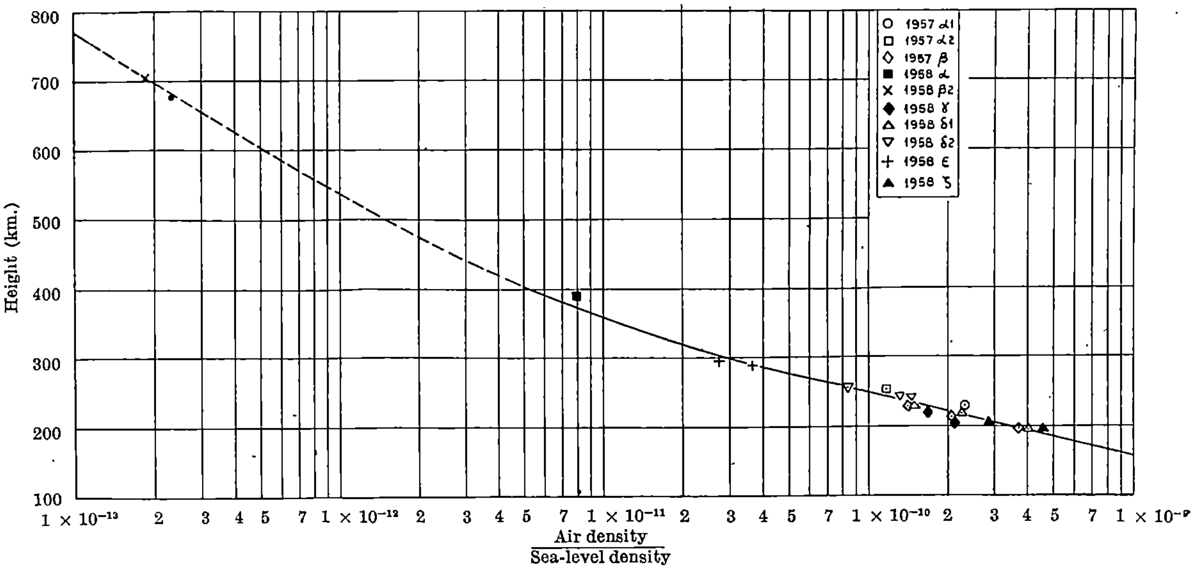

Fig. 2. Values of air density obtained from satellites 1957 α–1958 ζ, using equation 5

The air temperature should, in theory, be obtainable from the slope of the curve in Fig. 2; but in practice the accuracy is poor. Values of the coefficient H of equation 3 derived from the slope of the curve in Fig. 2 rise from $H = 37$ km. at 200 km. height to $H = 71$ km. at 400 km. height. But it is possible to link the points in Fig. 2 with other curves, of different slopes. For example, a straight line between 200 and 400 km. height, with $H = 50$ km., fits the points almost as well. There are other ways of finding H, the most direct being to use the equation connecting eccentricity e with perigee distance from the centre of the Earth, r_p. The appropriate expression for H, accurate to $\pm$ 5 per cent if $0{\cdot}015 < e < 0{\cdot}2$, is found (D. G. King-Hele and G. E. Cook, unpublished work) to be:

$$H = \frac{r_{p_0} - r_p}{\frac{1}{2}\ln\left\{\frac{ae}{a_0e_0}\left(\frac{8a_0e_0 - 3H}{8ae - 3H}\right)^2\right\} - \frac{a_0e_0 - ae}{a_0}} \qquad (7)$$

where zero suffix denotes initial values. This equation, like equation 2, is not significantly altered by the effect of the oblateness of the Earth. The value of H obtained from equation 7, using kinetheodolite observations of *Sputnik* 2, is $H \simeq 55$ km. at 200 km. height. It is, at present, difficult to choose between these rather scattered values of H. It seems probable however that, at heights between 200 and 400 km., the average value of H is near 50 km., and that H tends to increase with height. If a value had to be chosen, H might be assumed to rise from 45 km. at 200 km. height to 60 km. at 400 km. height, with an error-factor which should not exceed 1·5.

At heights between 200 and 400 km., the air temperature in degrees Kelvin may be expressed approximately as $1{\cdot}1\, MH/(1 - H')$, where M is the molecular weight of the air, H is in kilometres, and H' is the rate of change of H with height. The main constituents of the air at these heights are believed to be atomic oxygen and atomic nitrogen, in proportions as yet unknown[12,24–26]. If, then, M is taken as 15 and $H' \simeq 0{\cdot}07$, the average temperature between 200 and 400 km. height will be about 1,000° K. It should be emphasized, however, that any values of temperature are far less reliable than values of density.

I wish to thank Mrs. D. M. C. Walker for preparing the graphs in this article.

Table 2. Average Air Density at Heights between 200 km. and 400 km.

Height (km.)	Air density / Sea-level density	Density (gm./c.c.)
200	$3{\cdot}4 \times 10^{-10}$	$4{\cdot}1 \times 10^{-13}$
220	$2{\cdot}0 \times 10^{-10}$	$2{\cdot}5 \times 10^{-13}$
240	$1{\cdot}2 \times 10^{-10}$	$1{\cdot}5 \times 10^{-13}$
260	$7{\cdot}6 \times 10^{-11}$	$9{\cdot}3 \times 10^{-14}$
280	$4{\cdot}6 \times 10^{-11}$	$5{\cdot}6 \times 10^{-14}$
300	$2{\cdot}9 \times 10^{-11}$	$3{\cdot}6 \times 10^{-14}$
320	$2{\cdot}0 \times 10^{-11}$	$2{\cdot}4 \times 10^{-14}$
340	$1{\cdot}4 \times 10^{-11}$	$1{\cdot}7 \times 10^{-14}$
360	$9{\cdot}7 \times 10^{-12}$	$1{\cdot}2 \times 10^{-14}$
380	$7{\cdot}1 \times 10^{-12}$	$8{\cdot}7 \times 10^{-15}$
400	$5{\cdot}3 \times 10^{-12}$	$6{\cdot}5 \times 10^{-15}$

OBITUARIES

Dr. W. R. G. Atkins, C.B.E., F.R.S.

The death occurred on April 4 of William Ringrose Gelston Atkins at the age of seventy-four. Son of the late Thomas Gelston Atkins, M.D., of Cork, W. R. G. Atkins was born on September 4, 1884. After his schooldays at the Friend's School, Newtown, Waterford, and the Grammar School, Cork, he went to Trinity College, Dublin, where he took two honours degrees in physics and chemistry, and in botany, zoology and geology. He was awarded Senior Moderatorships in Experimental and in Natural Sciences in 1906, and was then successively assistant, during 1906–11, to the late Prof. S. Young, the University professor of chemistry, and during 1911–20, to the late Prof. H. H. Dixon, the University professor of botany, in Trinity College, Dublin. The latter period was broken by the First World War, in which Atkins was an assistant chemist at Woolwich Arsenal in 1915 and a volunteer assistant in the Division for Aeronautical Chemistry of the National Physical Laboratory for the first six months of 1916. As a result of his work at the National Physical Laboratory, he was given a commission as equipment officer in the Royal Flying Corps to organize and direct a laboratory in the Experimental Aircraft Establishment at the Aboukir Depot in Egypt, reaching the rank of major in the Royal Flying Corps. After the War he went for a short time as indigo research botanist at the Imperial Department of Agriculture in India.

In 1921, Atkins was appointed head of the Department of General Physiology at the Plymouth Laboratory of the Marine Biological Association, where he remained until his retirement in 1955, apart from the years of the Second World War, when he served successively in the Home Guard, the Royal Army Medical Corps, and the Meteorological Office.

Atkins's research work thus falls into two distinct periods, that at Trinity College, Dublin, and that at Plymouth. During the first period it was mainly physico-chemical, including such subjects as the properties of urine and the osmotic pressures of blood and eggs of birds, and of plant tissues. While in Egypt he was specially concerned with the deterioration of fabrics and the study of lubricants. In 1916, he published a book entitled "Some Recent Researches in Plant Physiology".

On his arrival at Plymouth Atkins thus had a very wide background on which to draw for his new field of research, which was the physical and chemical conditions of sea water as an environment for marine life. During his long period at Plymouth he undertook researches, the results of which are now basic to all modern research on the productivity of the sea and have passed into essential background knowledge. These related chiefly to the seasonal variations in the chemical conditions, especially the nutrient salts, in sea water; and to the penetration of light into the sea and the effects of fine particles in suspension. In the latter field Atkins collaborated with Dr. H. H. Poole, of the Royal Dublin Society. As a side-line, Atkins continued work started in Egypt on the deterioration of fabrics, in this instance experimenting on methods of preservation of nets and ropes. His researches on chemical and physical conditions in the sea brought considerable fame to the Plymouth laboratory.

Atkins was an indefatigable research worker, and a noteworthy feature was the way in which he adapted his methods to many environments. For example, his chemical work on sea water was repeated on freshwaters and soils; and his measurements of light were made on land, in woods and in many parts of the world. For many years he ran a continuous light recorder on the roof of the Plymouth Laboratory. He also gave liberally of his advice in many spheres during the Second World War. The range of subjects on which he published is too wide to include in this brief notice.

Atkins held the degrees of M.A. and Sc.D., and was a Fellow of the Royal Institute of Chemistry and of the Institute of Physics; in the First World War he was twice mentioned in dispatches and was awarded the O.B.E. (Mil.) in 1919. He was elected a Fellow of the Royal Society in 1925, and in 1928 he received the Boyle Medal of the Royal Dublin Society. In 1951 he was appointed a Commander of the British Empire in the King's Birthday Honours. He was president of Section K (Botany) of the British Association for this year's meeting in York.

In his earlier days at Trinity College Atkins was an athlete, and besides playing hockey and rowing at Trinity College, he was especially noted for his boxing. He became middle-weight champion of Ireland.

A man of great integrity and kindness, he had very many friends from all parts of the world, to whom he and his wife extended much hospitality at their home at Antony in Cornwall. To Mrs. Atkins, and their married son, all who knew him will extend their sympathy. F. S. Russell

Prof. Erik Hägglund

Erik Hägglund died in Stockholm on March 13 at the age of seventy-one. His life was dedicated to the elucidation of the involved reactions in processing wood into cellulose and paper, more particularly the chemistry of the sulphite pulping process, its technology, and the nature of lignin and its secondary derivatives.

Hägglund obtained his scientific education at the University of Stockholm, being fortunate to come under the guidance of an inspiring teacher, Hans von Euler. He received his doctorate in 1914, presenting a thesis on the effect of *p*H on alcoholic fermentation. It is one of the very first critical investigations of modern type on hydrogen ion concentration. By the way, Hägglund was the first of von Euler's research students to become the incumbent of a university chair in chemistry among the twelve future professors who emerged from the Euler fold. Hägglund graduated three months before the outbreak of the First World War, during which research and chemical technology were given a potent impetus for the sake of national economy and feeding of the people. A few years earlier, the method of fermenting the sugars of waste liquor from the sulphite-pulping process had been worked out in Sweden, a method still used and of great importance in Scandinavia. Hägglund had already, in 1911, been investigating this problem at the University of Stockholm, collaborating with the inventors of this process. He was thus predestined for an industrial position. The step from the university to industry was then very unusual, in Sweden at least. However, Hägglund found his right field of work and contributed substantially to the ultimate success of the 'sulphite–alcohol' venture. The first and, even by now, the only scientific account of this interesting fermentation is given in his monograph, "Die Sulfitablauge und ihre Verarbeitung auf Alkohol" (1921).

It was quite logical for a man of Hägglund's acumen to inquire further into the problem of converting wood into alcohol—the hydrolysis of the main constituent of wood, the cellulose—to produce fermentable sugars. This difficult problem had already received a great deal of attention in many quarters, but in vain. The only technique of practical use existing is that developed by Hägglund and Bergius, the so-called Rheinau-method (1917) in which hydrochloric acid is used as hydrolysing agent.

The great ability of this young scientist in solving intricate technical problems by application of fundamentals was early recognized in academic circles. In 1920, Hägglund accepted the chair of the chemistry of wood products especially established for him at Åbo Akademi, the Swedish-language university of the new Republic of Finland. A flourishing school of cellulose research came into being, the research output became formidable and many of the fundamentals of the speciality established. Hägglund's work formed a continuation of that of the grand old man of lignin chemistry, Peter Klason, emeritus professor of chemical technology in the Royal Institute of Technology in Stockholm. Actually, Hägglund became the spiritual successor to Klason in 1930, when a chair in wood chemistry and technology was founded at the Royal Institute, through donations from the pulp and paper industries. Fourteen years later, the Swedish Government erected an institute for pulp and paper research, probably the largest and best equipped institute of its kind at that time, constituting a unit of the Royal Institute.

Hägglund and his many pupils—of whom quite a number occupy leading positions in this key-industry of Sweden at the present time—have, during the past twenty-five years, investigated practically every phase of the wood-pulping processes and paper making. Work of a fundamental theoretical nature as well as important contributions to technological aspects of this industry, which is, of course, of great importance for Sweden, have emanated from the Hägglund school. Among his numerous co-workers, Adler, Enkvist, Erdtman, Giertz and Johnson were prominent. It is generally conceded that Hägglund did more than any other single individual to unravel the intricacies of the 'cooking' processes—his research on the formation of lignosulphonic acids being particularly outstanding. His comprehensive text-books, "Holzchemie" (1928, 1939), "Natronzellstoff" (1926) and "The Chemistry of Wood" (1951), are standard works throughout the world.

His unflagging endeavour in furthering the progress and well-being of the industry to which Hägglund devoted his life gave him an international standing. He was a member of many learned societies at home and abroad and received several honorary degrees, that from the University of Heidelberg giving him great pleasure. Among numerous awards he received was the rare distinction of the Grand Gold Medal of the Royal Swedish Academy of Technical Sciences, and the greatest honour to be given a cellulose chemist, the Ekman and Mitscherlich Gold Medals.

Hägglund was a sterling character, an inspiring colleague and a staunch friend. He will be greatly missed by a large circle of friends and colleagues in many lands.

K. H. Gustavson

Prof. Alfred Kohn

Alfred Kohn, professor and director of the Department of Histology of the German University in Prague until 1937, died in Prague on January 15, five weeks before his ninety-second birthday. Born in Libin, Bohemia, he received his medical education at the German University in Prague and, while still a student, became assistant to the histologist, Siegmund Mayer, whom he later succeeded in the chair. For various periods in his career he was a senator of the University and dean of its medical faculty.

Kohn is famous for his work on the parathyroids, which he termed *Epithelkörperchen*. His contribution was to point out clearly their independence of the thyroid. He was, at least, a silent partner in Gudernatsch's discovery, made in Kohn's institute, that feeding thyroid to tadpoles inhibits their growth but accelerates metamorphosis. His best-known work deals with the paraganglia and the chromaffin system, which terms he introduced. There has been much dispute about the nature of paraganglionic cells, but recent electron microscopical investigations bear out his views. Kohn considered chromaffin cells to be a special category, comparable with epithelium, nerve cells, muscle cells and so forth. They form a link between nervous and endocrine systems. Kohn also made significant contributions to our knowledge of the differentiation of the peripheral nervous system, stressing the early differentiation of nerve cells ("*primogenitur*", *Hauptzellen*) and the later differentiation of Schwann cells, paraganglia and suprarenal medulla ("*secundogenitur*", *Nebenzellen*).

I worked with him for ten years, and in my view Kohn should be considered a great clarifier who put into focus many structures and problems then only vaguely known or misinterpreted.

During the Nazi occupation of Prague, it seems that some informal protection was first extended to him, but when a *Diener* of the German Anatomy Department saw Prof. Grosser, the well-known embryologist, talk to the Jew, Kohn, in the street, the seventy-four year old Kohn was deported to a concentration camp. He returned to Prague in 1945, but he met new difficulties: on account of his German education and his position in the abolished German University, he was deprived of his superannuation; however, following protest in the Czech Press, it was restored. Later, the Communist government bestowed on this entirely unpolitical scientist the Order of Labour, which carries a supplemental income, thus making comfortable the last years of his life. Max Watzka, who succeeded him in Prague and is now editor of the *Anatomische Anzeiger* and professor of histology in Mainz, is, of all Kohn's disciples, the one who continues most consistently the work of Alfred Kohn.

Rudolf Altschul

NEWS and VIEWS

The Royal Society : New Foreign Members

The following have been elected foreign members of the Royal Society : Prof. Melvin Calvin, University of California, Berkeley, California, distinguished for his researches into the mechanism of photosynthesis ; Prof. Gerhard Domagk, University of Münster, director of the Research Laboratories for Experimental Pathology and Bacteriology, Farbenfabriken Bayer, Wuppertal-Elberfeld, Germany, distinguished for his researches leading to the discovery of 'Prontosil', the first chemotherapeutic agent against septic infection ; Prof. Jan Hendrick Oort, State University of Leyden, The Netherlands, distinguished for his contributions to the knowledge of galactic structure, of stellar distribution and of stellar dynamics ; Prof. Axel Hugo Teodor Theorell, of the Nobel Medical Institute, Stockholm, Sweden, distinguished for his work in the field of enzyme chemistry, particularly in relation to oxidation in animal tissues.

Overseas Geological Surveys :
Dr. Frank Dixey, C.M.G., O.B.E., F.R.S.

Dr. Frank Dixey will retire on June 30 from the post of director of Overseas Geological Surveys. Dr. Dixey graduated in the University of Wales in 1914. After service on the Western Front from 1915 to 1918 he was appointed government geologist in Sierra Leone. He worked in Africa for nearly thirty years, and was successively director of the Geological Survey of Nyasaland (1921–39) ; director of Water Development, Northern Rhodesia (1939–44) ; and director of the Geological Survey of Nigeria (1944–47). In addition, at various times in the years 1938–44, he carried out advisory work on water development and on geological survey matters for the Governments of the Sudan, Eritrea, Kenya and Tanganyika. In 1947 the Directorate of Colonial Geological Surveys was inaugurated as a central organization in London to link and provide specialist services for the surveys overseas, and Dr. Dixey became its first director. There were then eleven Colonial territories with Geological Survey Departments. In the next ten years surveys of thirteen other territories were organized ; the number of senior staff overseas was increased from 50 to 212 ; Photogeological and Geophysical Sections were set up in London ; the Mineral Resources Division was formed by transfer from the Imperial Institute, and its activities were extended ; and among many other developments, arrangements were made for extensive co-operation with universities and other institutions in the United Kingdom. The establishment of this thriving organization is the climax of an official career during which Dr. Dixey has been the author of more than 130 publications, relating mainly to Africa. Their range includes mineral resources and water supply, Karroo and Mesozoic stratigraphy, the rift system, many aspects of geomorphology, and petrological topics, including work in collaboration with Dr. W. Campbell Smith and Mr. C. B. Bisset which afforded the first recognition of carbonatites in Africa. Dr. Dixey was awarded the Draper Medal of the Geological Society of South Africa in 1945, and the Murchison Medal of the Geological Society of London in 1953. Since 1948 he has been president of the Association of African Geological Surveys.

Dr. S. H. Shaw, O.B.E.

Dr. S. H. Shaw has been appointed to succeed Dr. Frank Dixey as director of Overseas Geological Surveys. Dr. Shaw, who is fifty-five, graduated in 1926 at the Royal School of Mines with first-class honours in mining and mining geology. From 1926 to 1928 he worked with the late Dr. A. Broughton-Edge on electrical prospecting in what is now the copper-belt in Northern Rhodesia, and from 1928 to 1930 in Australia as a member of the Imperial Geophysical Experimental Survey. He then returned to the Royal School of Mines as a demonstrator in the Experimental Department. In 1932 he joined the staff of the Geological Department of the University of Birmingham, where he continued his work on the development and application of various methods of geophysical prospecting, including resistivity measurements in boreholes. At the invitation of the Government of Southern Rhodesia, he visited that country in 1933 to make tests of resistivity methods for locating underground water supplies, with results which led to the adoption of these methods as standard procedure. In 1937 Dr. Shaw was appointed as government geologist in Palestine, where he served until the termination of the mandate in 1948. In 1949 he joined the Directorate of Colonial Geological Surveys, and was charged with the task of initiating and developing the Photogeological and Geophysical Sections. He was promoted to deputy director in 1950. Dr. Shaw's publications include part-authorship of the official report of the Imperial Geophysical Experimental Survey, and a series of papers on resistivity work and on the estimation of free quartz in rocks by micrometric methods.

Geology at Leicester :
Prof. P. C. Sylvester-Bradley

Peter Colley Sylvester-Bradley, appointed to the recently created chair of geology in the University of Leicester, was educated at Haileybury and the University of Reading. After a short period in charge of the Department of Geology at the Seale-Hayne Agricultural College (1937–39) he served in combined operations, and later as administrative officer in a branch of the Admiralty Operations Division in the Mediterranean. His appointment to the staff of the Geology Department of the University of Sheffield followed in 1945, and there he now holds the post of senior lecturer in geology.

Bradley's comprehensive teaching experience also includes an appointment as visiting Rose Morgan professor in the University of Kansas during 1955–56. His researches in palæontology have dealt authoritatively with fossil Ostracoda, for he is part author and general co-ordinator of the volume dealing with these fossils in the "Treatise on Invertebrate Palæontology". Other fields of palæontological research are concerned with the fossil oysters of the Jurassic of north-west Europe, and with the ammonites of the Lias of the Yorkshire coast. His published work also bears witness to a deep interest in fundamental and philosophical aspects of palæontology, such as those concerned with the study of communities, with speciation, and with the taxonomic problems which arise therefrom. This varied and successful research activity has been recognized by the Geological

Society of London in the awards of the Wollaston Fund in 1953, and the Edmund Johnston Garwood Fund in 1957.

Bradley's active participation as a member of council of a number of geological societies and associations, together with a period (1953–57) as editor of the Yorkshire Geological Society, is a measure of the importance of his contribution to, and interest in, the welfare of his science. His enthusiasm and energy are combined with a strong and pleasant personality and his friends and colleagues look forward with anticipation to a most successful tenure of the chair of geology at the University of Leicester.

Ministry of Supply :
Mr. Lewis Boddington, C.B.E.

Mr. L. Boddington, a deputy chief scientific officer and director of Royal Naval Aircraft Research and Development at the Ministry of Supply, has been appointed to the rank of chief scientific officer, and will become the director-general of Aircraft Research and Development (R.A.F.) ; he succeeds Air Vice-Marshal P. S. Blockey, whose tour of duty with the Ministry of Supply expires in July. Mr. Boddington has been associated with research and development on naval aircraft and aircraft-carrier equipment during the greater part of his career. He joined the Royal Aircraft Establishment in 1936 and became superintendent of the Design Department in 1944. From 1946 until 1951 he was superintendent of the Naval Aircraft Department ; he was appointed to Ministry of Supply headquarters in 1951, and later became the director responsible for naval aircraft research and development. He has become recognized internationally as the leading authority on naval aeronautics, and his name has been associated with a number of important developments in this field. In particular, the angled deck, of which he was the joint inventor, and the mirror deck-landing sight, which was developed under his direction, have made the operation of aircraft from carriers very much easier and safer, and have been adopted by both the Royal Navy and the United States Navy. He has also been responsible for the planning and direction of the Royal Aircraft Establishment's new research facilities for naval aircraft at Bedford. In recognition of his services to the development of naval aircraft he was awarded the Bronze Medal of the Royal Aeronautical Society in 1953.

Science Correspondent of the B.B.C.: Mr. C. L. Boltz

The British Broadcasting Corporation has created a new post at Broadcasting House, that of science correspondent in the News Division. The post is comparable to that of the Division's diplomatic and industrial correspondents and will involve duties on both sound and television. Mr. C. L. Boltz has been appointed to the post. He joined the B.B.C. in 1952, as science correspondent on the European Service, and has been broadcasting to Europe ever since. Educated at Huish's School, Taunton, and at University College, Exeter, Mr. Boltz graduated in mathematics and physics, later taking a degree in psychology at Birkbeck College (University of London) with a view to research. After a period spent in research and teaching (during the War he taught radar at Hackney Technical College), he turned to science writing. Among his best-known books are "Wireless for Beginners" and "A Statue to Mr. Trattles". He has contributed to a number of scientific journals, including *Nature* and *Discovery*. He has been an active Fellow of the Physical Society for fifteen years and has served on the Colour Group's committee for two periods. Few people have had so wide an experience of science broadcasting, for during the time he has been broadcasting from Bush House he has covered a vast range of scientific topics. Among European listeners he has a great reputation and he is one of the most popular broadcasters to give talks at Bush House.

International Commission on Higher Education in Nigeria

It was announced on April 27 that the Nigerian Government has invited a Commission comprising Nigerian, American, and British members to investigate Nigeria's needs in post-secondary education over the next twenty years, and to recommend to the Nigerian Government what steps should be taken to meet these needs. The cost of this operation is to be met by a grant from the Carnegie Corporation of New York. Sir Eric Ashby, Master of Clare College, Cambridge, has accepted an invitation to be chairman of the Commission. The names of other members of the Commission will be announced when they have all accepted invitations. It is proposed that the full Commission should meet in Nigeria in January and again in August 1960, and should produce a preliminary report for the Nigerian Government by October 1960, when Nigeria attains full independence.

Intelligence Unit for Natural History

The formation last year of the Council for Nature (*Nature*, 181, 867 ; 1958) has given cohesion to the natural history movement in Great Britain, but there is a fundamental need for a central information service on matters concerned with natural history and nature conservation. At present there is no authoritative source of up-to-date information on these subjects available to naturalists. The B.B.C. has agreed to make an annual grant of £5,000 for three years to enable the Council for Nature to establish an Intelligence Unit, the first task of which will be the collection of information on what work is at present being undertaken by individual naturalists and by societies and various other bodies. By the end of the year it should be possible for the Council to provide information and advice, and to foster co-operation schemes of work and intimate what is required in the investigations of neglected fields of work. In particular it is hoped that help and encouragement can be given to amateur cinematographers wishing to make nature films. These are very important in fostering an interest in wild life in a population which is becoming increasingly urban. The Council for Nature (41 Queen's Gate, London, S.W.7) is grateful to the B.B.C. for its support, which is unconditional and places no restraint on the general services to all.

Space Research in Britain

In replying to a question in the House of Commons on April 20, the Minister of Supply, Mr. A. Jones, said that the United Kingdom missile programme could, with some adaptation, give an initial launcher in aid of a space research programme, but of itself could provide neither the satellites nor the instruments needed to attack the scientific problems of space research. The Government was at present considering the question of a British space research project using Earth satellites in the light of advice from the

Advisory Council on Scientific Policy. The Government had in mind the scope such a project would provide for co-operation with Commonwealth countries, but such discussions could most profitably proceed when the scale and nature of any British effort had been decided. Mr. Jones agreed that the danger of losing our youngest and ablest scientists to the United States in the absence of occasional opportunities for such research, even if it involved using equipment originally designed for a specific military purpose, was an important consideration. Mr. Jones promised that a statement would be made quite soon.

Commercial Manufacture of Nuclear Fuel Elements

In reply to a question regarding the circumstances in which a private company was permitted to manufacture nuclear fuel elements, and the security reasons for the refusal of the Parliamentary Secretary to the Ministry of Power to reveal, on April 21, which organization other than the Atomic Energy Authority was preparing to make such elements, the Prime Minister stated that the Parliamentary Secretary was unwilling to go into greater detail until he had been able to refer to the defence authorities as to whether any question of security arose. Mr. Macmillan now saw no objection to stating that it was the intention that Rolls-Royce, Ltd., should manufacture fuel elements for nuclear submarine machinery. The material would be supplied by and would remain the property of the Admiralty. At present all nuclear fuel was manufactured by the Authority, but it was likely that in future elements would be manufactured in some of the processes of industry. The Nuclear Installations (Licensing and Insurance) Bill at present under consideration in Committee ought to provide for this, and all such material would either be the property of the Authority or manufactured only under licence and control, for which the Bill set up a proper system. Except for a certain amount of processing, Mr. Macmillan thought that for many years all nuclear fuel would be supplied either by the Atomic Energy Authority or, for defence purposes, by the Defence Departments.

The Royal College of Surgeons of England

The recent intense activity in the Royal College of Surgeons, which has aroused considerable interest among both the professional and lay public, is not in fact a recent development. Before the Second World War the scientific work undertaken by the College had been extended by adding a Department of Physiology to the old-established Departments of Anatomy and Pathology in Lincoln's Inn Fields, London, and by establishing a centre for experimental surgical research, the Buckston-Browne Farm, at a site adjacent to Darwin's old home at Downe. But since the War, the programme of research and education has gained fresh impetus from the need for reconstruction after the grievous damage which the College suffered in 1941, and from the needs of postgraduates seeking higher qualifications in surgery, dental surgery and anæsthetics. When planning the rebuilding of the College, the Council therefore resolved that laboratories should take the place of some of the destroyed museums, and that Departments of Pharmacology and Biochemistry should be established to provide a complete syllabus of postgraduate education in the basic medical sciences which would be available not only to young surgeons but also to all postgraduates studying for any of the higher diplomas for which these subjects are required. Recognizing that teachers must be provided with accommodation and equipment for research if a high academic standard is to be maintained, the College included in its building programme a very considerable expansion of the floor area for laboratories as well as a corresponding extension of the Library. These plans were designed to discharge what the Council regarded as its plain duty to postgraduates, and to meet its ancient obligation to promote the science as well as the art of surgery.

In making these decisions the Council had to face the problem of finding the money to pay for new buildings and to maintain the new research departments. Fees from students and the welcome contribution from the University of London through the British Postgraduate Medical Federation provided only a small fraction of the sums required, which now stand at £350,000 to complete the buildings and an annual £150,000 for the salaries of teachers, research workers and technicians and for laboratory maintenance. The College exerts a far-reaching influence upon the National Health Service, but is not a hospital and therefore is not eligible for a direct grant from the Government. The Fellows have contributed handsomely to College funds, thus showing their confidence in the policy of the Council; but in order to raise these large sums of money an appeal to the public for funds has recently been launched. Already most generous support has been forthcoming from the friends of the College in industry, commerce and in the world of finance, whose example should be followed by many others who have the understanding and the vision to see that by supporting surgical research and education they are promoting the best interests of themselves, their families and their dependants.

Italian Nuclear Research Centre at Ispra

The President of Italy, Signor Gronchi, formally opened the Italian Nuclear Research Centre at Ispra on April 13 before a distinguished gathering of about a thousand people. Ispra is about a mile from the extreme south of Lake Maggiore and about 35 miles from Milan, with which it is connected by *autostrada*. The centre is set in a beautiful district and occupies 340 acres of part grassland and part woods. Ultimately it should have a working population of around a thousand. Work began on the site in the late summer of 1957 and later in the year an organization headed by Prof. Carlo Salvetti was set up in Milan to prepare for the move to Ispra. About three weeks before the official opening of the centre, *Ispra*-1, a 5-MW. heavy water-moderated research reactor, fueled by 20 per cent enriched uranium with a fast neutron flux of $1 \cdot 1 \times 10^{14}$ n/cm.^{2} sec. and a thermal neutron flux of 8×10^{13} n/cm.^{2} sec., went critical. This reactor is a modification of the *CP*-5 reactor at the Argonne National Laboratory which operates at 1 MW. The moderator and fuel for the reactor were imported from the United States, as were some of the most important reactor components, so as to speed up the construction of the reactor. At the opening ceremony the United States Atomic Energy Commissioner, Mr. Floberg, made a speech in Italian and handed a cheque for 350,000 dollars to President Gronchi as the American contribution to the cost of the reactor.

Ispra-1 is enclosed in a gas-tight metal cylinder, 79 ft. high, which is kept at a negative pressure as a safety measure. Several laboratories are grouped around the reactor, and a metal chimney stack, more than 200 ft. high, towers over the metal shell. The reactor is intended primarily for research purposes and its scope of activities is very similar to that of the *Pluto*-type reactors, to which it bears some resemblance. The Ispra centre will provide a valuable addition to the Italian nuclear scene, which includes the centre for fundamental research at Frascati and the new centre for research studies to be built near Rome. Italy, in common with most countries in western Europe, is increasing its consumption of power at the rate of about 7 per cent a year, and with the hydroelectric power potential in the north fully exploited, Italy has begun a nuclear power programme that should give a capacity of 500 MW. by 1964. At present the 200-MW. reactor being built by the Nuclear Power Plant Company for Agip Nucleare is the most advanced of the reactors under construction.

Braille Translation by Computer

IBM MATHEMATICIANS, working with the American Printing House for the Blind, have developed a process for translating printed text into Braille by computer. The computer used is an *IBM* 704 which can convert a 300-page book into Braille in an hour—a job that would take skilled translators more than six days. This new technique will make available many school and technical books now rarely produced in Braille, thus enlarging the possibilities for careers for the blind. To speed this translation, printed texts will be recorded on magnetic tape and distributed to IBM computer installations, where they will be translated and the cost borne by IBM United Kingdom, Ltd.

Writing Braille requires knowledge of many complicated rules, the symbols often changing their meaning in a different context. Braille consists of 63 combinations of six raised dots which represent not only the letters of the alphabet, numerals and punctuation marks, but also 183 special contractions and abbreviations, as in the case of shorthand. Texts to be translated by the computer are first transcribed on to punched cards. The cards are then fed directly into the computer, which has had previously stored in its memory a programme for conversion of English into Braille. The translated text emerges from the computer in coded symbols on punched cards, and these, in turn, are fed to the printer unit of the *IBM* 704, which reproduces Braille symbols above the English text. After editing, the corrected punched cards are fed into an embossing machine which produces metal plates ready for use on a rotary press.

Denudation and Burial of Archæological Structures

THE British Association (Section *H*) has formed a special committee to "investigate by experiment the denudation and burial of archæological structures". The aim of the committee, the members of which are Dr. G. W. Dimbleby (chairman), Dr. P. Jewell (secretary), Prof. R. J. C. Atkinson, Dr. I. W. Cornwall and Dr. B. Proudfoot, is to obtain precise measurements of the rates at which soil moves and accumulates, how far buried objects may move in the soil, and the way in which buried objects disintegrate and decay. Building a simple ditch and bank with incorporated markers, and following the rate of silting of the ditch, and of denudation and spreading of the bank, formation of turf and compaction of soil, over the following years would help to answer some of the questions. Comparative results will be obtained from sites established in different parts of Britain. The observations should not only aid in the interpretation of archæological excavations but may throw more light on the changes that past land-use has produced. Buried materials will include wood, charcoal, bone and metal, treated in different ways, and their examination in the future may enable more information to be obtained from the accumulating finds from archæological sites. The committee will be very glad to hear from anyone interested in the project, particularly those whose specialist knowledge might help in laying out the structures, and who in turn might derive information of interest from the experiments. The secretary of the committee is Dr. P. A. Jewell, Royal Veterinary College, London, N.W.1.

A Century of Biological Research in Illinois

THE Illinois Natural History Survey Bulletin (27; 1958), entitled "A Century of Biological Research" (Pp. vi+85–234. Urbana: Illinois Natural History Survey, 1958), deals with the development of biological research in a mainly agricultural community, in which the practical problems affecting land-use and agriculture have largely controlled the outlook of the investigators as well as the policy controlling development. This is reflected in the five main lines of progress summarized, namely, economic entomology, faunistic surveys, applied botany and plant pathology, aquatic biology, and wild-life conservation. The work has, however, included notable contributions of a fundamental nature, and the brief outlines of these included in this Bulletin are of considerable interest. The rapid changes in Illinois due to the transformation of woodland and swamp to farmland, and to the utilization of the now 'vanishing prairies', have all greatly affected the plant and animal populations. These have been followed in studies and records which can scarcely be paralleled anywhere over so long a period. As one example, map records are given of the density of populations of a wheat predator, the chinch bug (*Blissus leucopteris*), available since 1840. Other examples trace the gradual disappearance of prairie animals, such as the prairie chicken, as arable land has replaced grassland, while the recorded fluctuations of the bob-white quail or of ducks and geese or of introduced pheasants, in areas of diverse ecological character, have abundantly justified the bird-census techniques which were adopted at an early date. Very well known to fresh-water biologists are the massive pioneer papers on the plankton, bottom-fauna and fishes of the Illinois River. Not only do they record some of the earliest quantitative work in these fields but also the 'indicator' species present and succeeding one another, as drainage and pollution modified the character of the river. This Bulletin is therefore a valuable guide to records which trace the growth of modern aspects of wild-life conservation from earlier efforts concerned simply with crop protection. It is, incidentally, also a memorial to the genius and foresight of A. S. Forbes, who for so long guided the destinies of the organization.

National Science Foundation Fellowships

THE National Science Foundation has awarded 1,100 graduate fellowships in the natural sciences and allied fields for the academic year 1959–1960. In addition, the Foundation has announced the names of 160 winners of regular postdoctoral fellowships. Of the graduate awards, 216 were made in the life sciences, 866 in the physical sciences, including a number in interdisciplinary fields, and 18 awards were made in certain areas of the social sciences. Of the postdoctoral awards, 55 were made in the life sciences, and 104 in the physical sciences, including a number in interdisciplinary fields, and in the field of econometrics.

The Genetic Concept of the Origin of Cancer

THE theory that malignant transformation in cells may be considered to be a genetic event was suggested in 1908 by J. A. Murray of the Imperial Cancer Research Fund (London), but experimental evidence had to wait twenty-years until inbred mice were available. In this respect the credit is due to the pioneering work of Dr. L. C. Strong (Buffalo), who was the organizer and chairman of a conference on "The Genetic Concept for the Origin of Cancer", supported by the New York Academy of Science and the National Institutes of Health (Bethesda). The papers presented by 29 contributors at the Conference, which was held in New York, October 1957, have now been published (*Ann. N.Y. Acad. Sci.*, 71; 801–1241; 1958). They are representative of the various aspects of cancer research of the past three decades. The diverse subjects discussed include: the role of genetic and environmental influence in the causation of experimental cancer; the effect of selection on transplanted tumours; the occurrence of tumours in plant and animal interspecific hybrids; the modifying effects of genes on melanotic tumours in the fruit fly *Drosophila*; the nature of carcinogen-induced mutations in *Neurospora*.

J. Schultz (Philadelphia) attempted to show how our knowledge of genetical changes in somatic cells can be related to malignant change. D. B. Amos (Buffalo), on the other hand, gave examples to illustrate how the antigenic patterns of tumours can be used as a tool to study somatic genetics. The relationship between chromosome changes in tissue culture of mammalian cells and those observed in tumour cells was brought to the fore by A. Levan (Lund) and J. J. Biesele (New York); the possible relevance of certain types of phage mutations to malignant transformation of cells was discussed by S. E. Luria (Urbana). Papers by P. A. Gorer (London) and C. P. Oliver (Austin) deal with the genetics of human cancer, both agreeing that genetically determined predisposition to a particular type of cancer is present in certain families.

Royal Institute of Chemistry: Officers

MR. E. LE Q. HERBERT, managing director of Shell Refining Co., Ltd., was recently elected president of the Royal Institute of Chemistry for 1959–61. He took over this office from Dr. D. W. Kent-Jones (president 1955–57), who had been acting president since the death, on December 19, 1958, of Prof. W. Wardlaw (elected president for 1957–59). Dr. C. W. Herd, Prof. Charles Kemball and Mr. Clifford Paine were elected vice-presidents for 1959–61. Prof. Harold Burton was re-elected honorary treasurer for the ensuing year.

Iron and Steel Institute: Changes on Council

The following new members were recently elected to the Council of the Iron and Steel Institute: *President*, Mr. W. Barr; *Honorary Treasurer*, Sir Julian Pode; *Vice-Presidents*, Mr. B. Chetwynd Talbot (chairman and managing director, South Durham Steel and Iron Co., Ltd.), Mr. C. H. T. Williams (managing director, Park Gate Iron and Steel Co., Ltd.); *Ordinary Members of Council*, Major W. R. Brown (chairman, Ashmore, Benson, Pease and Co., Ltd.), Mr. T. R. Craig (director, Colvilles, Ltd.); *Additional Honorary Members of Council*, Dr. N. P. Allen (director, Metallurgy Division, National Physical Laboratory), Mr. A. Jackson (technical adviser on steelmaking, United Steel Companies, Ltd.).

Announcements

DR. D. A. LONG, recently on the staff of the Medical Research Council at the National Institute for Medical Research and during 1957–58 visiting professor in microbiology in the School of Medicine at the University of Pittsburg, has been appointed chief medical adviser and head of the Medical Research Department of the Wellcome Foundation, Ltd.

THE Physical Society is holding a conference on "Co-operative Phenomena and Phase Transitions" at King's College, Newcastle upon Tyne, during July 6–7. Further information can be obtained from the Secretary, Physical Society, 1 Lowther Gardens, London, S.W.7.

UNESCO is holding an arid zone symposium at the Instituto Nacional de Investigaciones Agronomicas, Madrid, during September 24–30. Summaries of proposed papers must reach the Department of Natural Sciences, Unesco, Place Fontenoy, Paris VII, by June 1. Further information can be obtained from the above address.

A CONVENTION on "Television Engineering in Science, Industry and Broadcasting", organized by the British Institution of Radio Engineers, will be held in the University of Cambridge during July 1–5. Delegates may reside in the colleges of the University. Further details can be obtained from the Secretary, British Institution of Radio Engineers, 9 Bedford Square, London, W.C.1.

AT the summer conference of the Society for Applied Bacteriology, to be held in London during July 7–9, a symposium will be held on "Lactobacilli". Those interested in attending, or contributing to, this symposium can obtain further details from the honorary secretary, G. Sykes, Boots Pure Drug Co., Ltd., Microbiology Division, Standards Department, Nottingham.

THE fourteenth Annual Electronics Exhibition and Convention of the Northern Division of the Institution of Electronics will be held at the Manchester College of Science and Technology during July 9–15. It will include extensive displays of electronic equipment of interest in all branches of science and industry. Details can be obtained from the Honorary Exhibition Organizer, Mr. W. Birtwistle, 78 Shaw Road, Rochdale, Lancs.

A MATHEMATICAL colloquium is to be held under the auspices of the Edinburgh Mathematical Society in University Hall, St. Andrews, during July 8–18. The principal speakers will be: Prof. H. S. M. Coxeter (subject to be announced), Prof. V. C. A. Ferraro (magnetohydrodynamics), Prof. C. Lanczos (linear operators and function spaces), Dr. A. P. Robertson (functional analysis), and Dr. R. Schlapp (history of mathematics). Further particulars and forms of application can be obtained from Mr. J. R. Gray, St. Salvator's College, St. Andrews.

EDUCATION FOR GOVERNMENT

A DEBATE on the motion "That the education of our future rulers should be primarily in the sciences rather than the humanities" was held in the Beveridge Hall, Senate House, University of London, on March 18. Sir Cyril Hinshelwood was in the chair; the motion was proposed by Sir Alexander Fleck, seconded by Prof. A. R. Ubbelohde, and opposed by Prof. B. Farrington, seconded by Prof. W. Beare. The debate was sponsored jointly by the London Section of the Royal Institute of Chemistry, the London branch of the Classical Association and the Haldane Society.

Sir Cyril remarked, in opening the proceedings, that he supposed he owed his position on the fence on this occasion to the fact that he happened to be president of the Classical Association as well as president of the Royal Society. He asked that there should be a straight fight on the arts versus science issue implied in the motion, but in this he must have been rather disappointed. Scarcely a speaker could be found to defend the motion as worded, and it was necessary even for Sir Alexander Fleck to assure his audience that whatever he might say, he was, in fact, moving the motion. His reluctance to do so stemmed not only from his slender acquaintance with the classics—failures in Latin having on two occasions "almost wrecked an otherwise promising career"—but from his dislike of the term "our future rulers". Any suggestion of a Platonic *élite*, selected by some process of intellectual eugenics, was repugnant to him. But there was an urgent need to orient the education of the people as a whole so that the statesmen and leaders they produced would be capable of handling scientific ideas. He contrasted, not too seriously, the legendary pedantry and other-worldliness of the classical scholar, with the severely practical, positive approach which a scientific training could bring to the consideration of human affairs. He believed, with Lord Cherwell, that it was more important to know something of the properties of chlorine than of the improprieties of Clodius. The continued growth of science and of informed opinion about science was vital to our country and to all peoples.

Prof. Benjamin Farrington, in a persuasive speech, opposed the motion on the grounds that it appeared to imply that there should be a compulsory tilt in the whole educational system so as to give primary emphasis to science. He had no quarrel with science—we should spend even more of our resources upon it in the future than we do at present—but it was essential that science remained the servant, not the master. The transformation of human life by science in the past three hundred years had been remarkable, but it had produced problems to which science by itself had no answers. The problems raised by automation, for example, or the whole question of man's survival, were beyond purely scientific answers. The humanist could survey the whole development of the marvellous being we called Man. This did not imply a backward-looking philosophy: it was the only hopeful way of looking to the future. Man alone had the power of creating his own inner world, the world of ideas, and he had drastically changed life on earth by his rational acts. The human intellect was the greatest force in the universe, since it alone could produce change. Science was one of man's achievements, but it was not the only one of significance. Scientists often seemed excitable, unstable, and at the mercy of every new idea. They were apt to be misled into new superstitions and to confuse their abstractions and concepts with reality. Hence one heard of discussions about the psychology of the man-made machine, when no machine could possess consciousness. The study of conditioned reflexes in organisms was important, but they did not supersede the rational acquisition of knowledge. The humanist was concerned with the conscience of man, in which is enshrined all the long history of man's endeavour; he must remain master.

Prof. A. R. Ubbelohde was prevented from being present by illness and his speech in support of the motion was read for him. The role of science had changed completely since the time when Dr. Johnson had ruled that "speculations upon matter are voluntary, and at leisure". It was necessary to continue the age-old process of adapting the content of education to the requirements of a changing society and admit science to the priority. A knowledge of science should be as fundamental an element of education in the future as were reading, writing and arithmetic to-day. Our future leaders would be at a disadvantage if they had not had scientific training; to understand and control the power of science would be one of their prime responsibilities. We could not risk that the potentialities of applied science should be at the mercy of "humanistic Druids" whose sympathies lay wholly outside the sciences. Scientific knowledge now formed one of the major empires of the human intellect; its disciplines threw new light upon old problems of human existence. The scientist soon learnt a humility in the face of objective facts which would stand many a politician in good stead. He was also accustomed to co-operating with his fellows across national boundaries in an international community of endeavour. There were dangers in too narrow an approach in scientific studies, as there were in all academic studies, but these were recognized and could be avoided. It would be a far greater danger to leave our future rulers in ignorance of science.

Prof. W. Beare, in seconding the opposition, said that the fact that they were debating this motion showed that there was a widespread uneasiness about the objects of education. Since there was no clear answer it was important to preserve freedom of choice. The idea that the education of the whole community should be compulsorily slanted was dangerous. It were better that a man should be a first-rate historian than a second-rate chemist. Our citizens and voters would be better guided by a knowledge of history than of quantitative science, but the study of any subject could not, of itself, make a good citizen or ruler—it was the knock-about of everyday life which was the true education. He did not grudge the scientists their palatial new premises, even though a new hat-rack might prove to be more than could be managed for the arts faculty. But a knowledge of thermodynamics would tell you nothing about hell-fire; our rulers should come from the humanists who had studied the imperfections and sins of man, as well as his potentialities.

When the discussion was thrown open it soon became clear that the motion had found few friends. The first two speakers were classicists; Dr. R. E. Witt spoke from experience as a headmaster of a grammar school and said that the study of Greek seemed to produce a greater humility, a greater readiness to look on the other side of a problem, than the study of scientific subjects. Mrs. M. Lockwood suggested that our leaders should have a humanistic philosophy within which their problems could be judged. Scientific progress seemed frighteningly aimless and uncontrolled; there was a suspicion that the real spur to our scientific effort was simply fear of the U.S.S.R. Prof. Timonen, of the University of Helsinki, pointed out that some of the greatest scientists had had a sound classical education and that this had probably contributed to their clarity of thought and expression.

There followed contributions by four chemists, but only one favoured the motion. Dr. A. C. C. Newman urged the importance of inculcating moral values during the education of the citizen. Political leaders had to deal with issues which were primarily moral and human; so long as they were well advised on scientific questions that was enough. Dr. H. J. Barber suggested that the study of the history of science could provide a valuable synthesis of the humanities and the sciences; it should take its place in curricula along with political history. Mr. R. A. Frazer disliked the suggestion that the sciences should predominate in education—a balance should be struck with emphasis primarily on the humanities. Mr. F. F. Ross agreed that the learning of Latin was a valuable discipline in primary education, but it should give way to science later. An understanding of man's scientific progress was basic to the study of history.

Prof. Farrington, in replying for the opposition, deplored the fact that the necessary expansion of the science faculties of British universities had been accompanied by drastic reductions in the facilities for studying ancient and modern languages and cultures. This was bringing about an undesirable change in the character of the universities themselves.

Sir Alexander Fleck, summing up for the motion, strenuously denied that the motives for the expansion of science were political. Man might not live by bread alone, but bread was still a necessity, and it was up to science to provide it. Only if our leaders understood science could it be used to improve life on earth.

Sir Cyril Hinshelwood then put the motion to the meeting and it was heavily defeated. A vote of thanks to the chairman and the speakers, proposed by Dr. S. A. Miller, was carried with acclamation.

N. LINDOP

DETERGENTS, TEXTILES AND DYES

A CONFERENCE on "Detergents, Textiles and Colour", organized by the Textile Institute in collaboration with the Branded Textiles Group, was held on February 11 in the Lesser Free Trade Hall, Manchester. Mr. Roland Thomas (director, C.P.A., Ltd., Branded Textiles Group), opening the meeting, said that the products produced by the Group were guaranteed and that members of the Group were interested in maintaining high quality in a very large range of textile goods. Serious consideration had been given for two and a half years to problems arising from the new detergents; on the subject of deterioration of textiles, the detergent manufacturers' attitude to complaints had been that: (*a*) they were not true, (*b*) if true, it did not matter, (*c*) if it did matter, nothing could be done about it, and (*d*) if anything could be done, it would be too expensive. The problem was serious, the housewife was lost in the complexities of advertisements and it was the business of industry to find a solution.

In the morning three papers were read and a number of excellent demonstrations shown to illustrate loss of tint by lack of fastness of dyes to detergent mixtures, by contamination by fluorescent bleaches and by chemical bleaching.

Mr. C. F. Ward (on behalf of the Branded Textiles Group) referred to the great increase in recent years in the number and variety of textiles and also of detergents and substances added to the synthetic soaps. It was fortunate, he said, that in this change emphasis has been placed by the textile manufacturer more and more upon quality. He listed detergent requirements and mentioned the need for instructions understandable by the non-technical housewife. Detergent compositions were discussed, particularly the so-called optical bleaches—the colourless blue-fluorescing substances used to give the "whiter-than-white" look. The danger of transfer of these substances from one article to another in the wash was pointed out and, in particular, the most objectionable effect upon the tint of textiles originally dyed to pastel shades such as peach and nil which, after contamination by the fluorescent optical bleach, appear pink and dirty blue.

Complaints of faults caused by the chemical bleach in the detergent powder, such as 10 per cent sodium perborate, were described; in particular of a royal blue dye on wool which develops yellow patches and spots at temperatures as low as 110° F. Cellulosic materials develop pin-holes either through the action of particles of the bleach which have not been completely dissolved, or through local traces of metal catalysts causing violent action by the dissolved persalt. Fading of dyes in sunshine while drying on the line may be attributed to incomplete rinsing of alkali. Some optical bleaches are themselves not fast to light and discolour in sunlight. The quite common practice of the housewife adding bleach containing chlorine to a detergent when washing whites leads to further troubles; Mr. Ward said that he understood that organic chloro-compounds are already being added to domestic washing powders in the United States and are being considered for use in Great Britain. He viewed this with the greatest concern, since it would lead to increase of complaints of loss of colour, fading, local bleaching, and loss of wear.

Mr. Ward concluded by saying that the housewife is puzzled by the number of products and the various claims made for them; whereas he had no objection to optical bleaches for those who want them for whites, he did complain that colours of textiles are spoilt by them, and argued that there should be available a detergent containing no bleach and no optical brightener.

Mr. F. P. Thompson (Unilever Ltd.) then spoke on the problem from the point of view of the manufacturer of detergents. He gave the typical compositions of washing powders of the soap (classical carboxylate) and non-soap (synthetic detergents) types, shown in Table 1. Both contain 0–1 per cent of sodium carboxymethyl cellulose and 0·02–0·08 per cent of optical bleach.

Table 1

Soap	(per cent)	Non-soap	(per cent)
Soap	40–65	Sodium alkylanyl sulphonates	20–22
Sodium carbonate	5–20	Other wetting or frothing agents	0–5
Sodium silicate	3–5	Sodium polyphosphates	30–40
Sodium phosphate	0–10	Sodium perborate	10
Sodium perborate	0–10	Sodium silicate	5
		Sodium sulphate	20

Mr. Thompson claimed that perborates have negligible effects upon most dyes and that oxygenated bleaches do not cause loss of strength of textiles. Perborates give better removal of some soils than manual scrubbing. With reference to the bright blue dye which turns green or yellow, he said that no change in shade is produced by carboxylate soap; with perborate it changes shade gradually, the effect being greater in soaps than in synthetic detergents. The change in colour increases with temperature and with concentration of suds. Loss of strength of textiles is least for the carboxylate soap; but with perborate it is much the same for all types of soaps and detergents.

Mr. Thompson spoke of many reports that no discoloration is caused by repeated washing with optical bleaches. He spoke of the difference between the skills and desires of the housewife and the technical expert, and also of the education of domestic users which is carried on by the makers of detergents.

Mr. G. S. J. White (Imperial Chemical Industries Ltd.) gave a brief account of the outstanding advances in the discovery of new dyes, pointing out that major new discoveries occurred at intervals of about thirty years. The requirements of a dye were listed as, first, ease of application; secondly, colour fastness and, to-day, fastness to detergents; and thirdly, colour gamut. Most attention has been given and most success achieved in making products easier to apply. On the other hand, those dyes most easily applied are least fast, and fastness requires more expensive dyeing processes. A striking demonstration was shown of a blue dye which, when made soluble by sulphonation, is applied easily but shows serious loss of colour on washing. When the dye is chemically bonded by the more expensive process of attachment by the cyanuric chloride reaction, only slight loss of colour occurs. When made soluble by a quaternary nitrogen atom and fixed upon the fabric by dequaternizing, it is fast to detergent; but this is the most difficult and expensive method of dyeing.

Mr. White recalled the pre-war German label guaranteeing fastness of dyed textiles to detergents and light, and mentioned the present 'Felisol' label controlled by an international committee which tests dyes and dyeings. He regarded the flow of information from the dye maker to the dye user as very good, but pointed out the paucity of the return of information and complaints from users. He estimated the annual world expenditure on research by dye makers as £15 million, of which about £4 million was spent on the salaries of chemists. He concluded by claiming that the problem of the ultimate consumer who still encounters textile goods of poor washing fastness can broadly find alleviation, if not entire resolution, within the textile industry itself, using the whole wide range of products of the dye manufacturers.

Dr. A. S. C. Lawrence (Sheffield), opening the discussion, said that it was clear that the main reason for the meeting was the composition of detergent mixtures; that the meeting was held to discuss whether the additional obligation laid upon dyestuff makers and textile manufacturers by the composition of detergent mixtures is, first, more than they can be reasonably expected to meet to protect the interests of their users and their own good name; and, secondly, whether this additional obligation is necessary for improving detergents or if it is a passing and unnecessary phase which will die out in a few years.
